GS. Keyboard Shortcuts .......................................................................................................................78
GS. Services and Support Information .................................................................................................81
Nuclear Safety Related Features .........................................................................................................82

Chapter 2: What's New? ........................................................................................................................84
STAAD.Pro CONNECT Edition V22 ......................................................................................................84
   CONNECT Edition V22 Update 1 .......................................................................................................84
   CONNECT Edition V22 ......................................................................................................................90
STAAD.Pro CONNECT Edition ............................................................................................................91
   CONNECT Edition Update 3 ..............................................................................................................91
   CONNECT Edition Update 2 ..............................................................................................................98
   CONNECT Edition Update 1 .............................................................................................................103
   CONNECT Edition ..........................................................................................................................105
STAAD.Pro V8i ......................................................................................................................................108
   V8i (SELECTseries 6) .........................................................................................................................108
Chapter 3: Tutorials ................................................................. 373

T.1 - Steel Portal Frame .......................................................... 373
  T.1 Methods of creating the model ....................................... 373
  T.1 Description of the tutorial problem ............................... 374
  T.1 Creating a new structure ................................................ 375
  T.1 Creating the Model using the Physical Modeler ......... 377
  T.1 Creating the model using the analytical user interface ... 385
  T.1 Analysis and Design ....................................................... 412
  T.1 Viewing the input command file ................................... 427
  T.1 Creating the model using the command file ............... 428
  T.1 Performing Analysis/Design .......................................... 432
  T.1 Viewing the output file ................................................ 433
  T.1 Post-Processing ............................................................. 441

T.2 - RC Framed Structure .................................................. 449
  T.2 Methods of creating the model ..................................... 449
  T.2 Description of the tutorial problem ............................... 449
  T.2 Creating a new structure .............................................. 451
  T.2 Creating the Model using the Physical Modeler ......... 452
  T.2 Creating the model using the analytical user interface ... 458
  T.2 Analysis and Design ....................................................... 458
  T.2 Viewing the input command file ................................... 483
  T.2 Creating the model using the command file ............... 494
  T.2 Performing the analysis and design ......................... 499
  T.2 Viewing the output file ................................................ 501
  T.2 Post-Processing ............................................................. 506

T.3 - Analysis of a slab ....................................................... 535
  T.3 Methods of creating the model ..................................... 535
  T.3 Description of the tutorial problem ............................... 536
  T.3 Creating a new structure .............................................. 536
  T.3 Creating the Model using the Physical Modeler ......... 538
  T.3 Creating the model using the analytical user interface ... 539
  T.3 Analysis and Design ....................................................... 547
  T.3 Post-Processing ............................................................. 578
Chapter 4: Modeling .............................................................. 615
M. Navigating the Graphical View Window ................................................................. 615
M. To select a center of rotation at a node ................................................................. 615
M. To view a 3D rendering of your model ................................................................. 616
M. Labels .................................................................................................................. 617
M. Views .................................................................................................................. 623
M. To insert custom text in a view ............................................................................ 630
M. To display loads graphically .................................................................................. 631
M. To identifying beam start and end ....................................................................... 634
M. Rotation tools ...................................................................................................... 636
M. To display master nodes ...................................................................................... 638
M. Creating Model Objects ...................................................................................... 639
M. Drawing Aids ...................................................................................................... 639
M. Beams .................................................................................................................. 643
M. Physical Members ................................................................................................ 649
M. Plates ................................................................................................................... 653
M. Composite Decks ................................................................................................. 693
M. Solids ................................................................................................................... 696
M. Nodes ................................................................................................................... 697
M. Modify Your Model .............................................................................................. 699
M. Groups ............................................................................................................... 704
M. Structure Wizard .................................................................................................. 710
M. Pages in the Analytical Modeling Workflow ...................................................... 729
M. Properties and Specifications ............................................................................. 730
M. Section Profiles .................................................................................................... 730
M. Materials and Constants ...................................................................................... 788
M. Member Orientation .............................................................................................. 794
M. Member Specifications ......................................................................................... 797
M. Plate Specifications ............................................................................................... 805
M. Node Specifications ............................................................................................... 810
M. Supports ............................................................................................................. 812
M. To assign a fixed or pinned support ..................................................................... 812
M. To assign an enforced support ............................................................................. 813
M. To assign custom release supports ...................................................................... 814
M. To assign a spring support .................................................................................... 814
M. To assign an inclined support .............................................................................. 817
M. To assign a foundation support ............................................................................ 818
M. Loading Your Model ............................................................................................ 819
M. Available Structural Load Specifications in STAAD.Pro ................................. 819
M. To create a new primary load case ...................................................................... 822
M. Load Items .......................................................................................................... 823
M. Wind Loads ........................................................................................................... 835
M. Seismic Loads ...................................................................................................... 840
M. Response Spectra ................................................................................................. 842
M. Snow Loads .......................................................................................................... 851
Chapter 5: Analysis ................................................................. 928

A. Types of Analysis ......................................................................................................................... 928
A. To specify a linear elastic analysis ............................................................................................ 928
A. To specify a P-Delta analysis ...................................................................................................... 928
A. To specify a direct analysis ......................................................................................................... 929
A. To specify a nonlinear analysis .................................................................................................. 930
A. To specify a nonlinear cable analysis ......................................................................................... 931
A. To specify an imperfection analysis .......................................................................................... 932
A. To specify buckling analysis ..................................................................................................... 932
A. To specify a pushover analysis .................................................................................................. 933
A. To add a change command ...................................................................................................... 934
A. To generate a floor spectrum .................................................................................................... 935
A. To specify pre-analysis commands .......................................................................................... 936
A. To create a load list ..................................................................................................................... 937
A. To check for soft stories and seismic code irregularities .......................................................... 937

M. Notional Loads .............................................................................................................................. 852
M. Moving Loads .............................................................................................................................. 853
M. Time History Loads ..................................................................................................................... 855
M. Pushover Loads .......................................................................................................................... 861
M. To use starting vectors with load-depant Ritz vectors .............................................................. 865
M. Load Combinations .................................................................................................................... 865
M. To add a repeat load case .......................................................................................................... 872
M. To create a reference load .......................................................................................................... 873
M. Damping Modeling ...................................................................................................................... 874
M. Mass Modeling .......................................................................................................................... 876
M. To create a load envelope .......................................................................................................... 877
M. Piping workflow ......................................................................................................................... 878
M. Bridge Deck workflow ............................................................................................................. 883

M. Checking Your Model ................................................................................................................. 887
M. To check for multiple structures ............................................................................................... 887
M. To check for warped plates ....................................................................................................... 887
M. To check for and remove duplicate entities ............................................................................. 889
M. To detect and remove zero length members ........................................................................... 890
M. To check for overlapping collinear members ......................................................................... 891
M. To change a beam incidence .................................................................................................... 892
M. To detect and remove orphan nodes ....................................................................................... 892
M. To display the distance between two nodes ........................................................................... 892
M. To display beam lengths ........................................................................................................... 893
M. To check for negative volume solids ...................................................................................... 893
M. Physical Modeling workflow .................................................................................................... 894
M. Using the Physical Modeler ...................................................................................................... 894
M. To drop the associated physical model ................................................................................... 894
M. Building Planner workflow ...................................................................................................... 895
M. To start a STAAD Model in the Building Planner workflow .................................................. 895
M. Plans ........................................................................................................................................... 895
M. Slabs .......................................................................................................................................... 899
M. Columns ................................................................................................................................... 902
M. Beams ...................................................................................................................................... 904
M. Frames ..................................................................................................................................... 911
M. Analysis and Design ................................................................................................................ 923
Chapter 6: Design .............................................................. 944

D. Batch Design versus Interactive Design Workflows ................................................................. 944
D. Steel Design ................................................................................................................................. 944
D. Available Steel Design Codes ................................................................................................... 944
D. Batch Steel Design Operations ................................................................................................. 950
D. Steel Connection Design ........................................................................................................ 953
D. Concrete Design ....................................................................................................................... 1000
D. Available Concrete Design Codes ........................................................................................... 1000
D. Batch Member and Element Design Operations ...................................................................... 1002
D. Interactive Concrete Design ................................................................................................. 1005
D. Advanced Concrete Design .................................................................................................... 1352
D. Advanced Slab Design ........................................................................................................... 1353
D. Foundation Design .................................................................................................................. 1359
D. Aluminium Design .................................................................................................................. 1362
D. Available Aluminum Design Codes ........................................................................................ 1362
D. To specify aluminum design code and parameters ................................................................. 1363
D. To specify aluminum design commands ............................................................................... 1363
D. To generate aluminum take off ............................................................................................. 1364
D. Timber Design ....................................................................................................................... 1364
D. Available Timber Design Codes ............................................................................................ 1364
D. To specify timber design code and parameters ..................................................................... 1365
D. To specify timber design commands ..................................................................................... 1365
D. Design Codes ......................................................................................................................... 1366
D1. American Codes .................................................................................................................... 1366
D2. Australian Codes .................................................................................................................. 1627
D3. British Codes ....................................................................................................................... 1655
D4. Canadian Codes ................................................................................................................... 1695
D5. European Codes ................................................................................................................. 1742
D6. French Codes ........................................................................................................................ 1872
D7. German Codes ..................................................................................................................... 1880
D8. Indian Codes ......................................................................................................................... 1887
D10. Mexican Codes ................................................................................................................... 2002
D11. New Zealand Codes .......................................................................................................... 2021
D12. Norwegian Codes .............................................................................................................. 2046
D13. Russian Codes ................................................................................................................... 2113
D14. South African Codes .......................................................................................................... 2176

Chapter 7: Postprocessing and Reports .......................................................... 2212

P. To view analysis results ........................................................................................................... 2212
P. Postprocessing Workflow ...................................................................................................... 2213
P. To reposition support reaction labels .................................................................................... 2213
P. To create a animated video file from analysis results ............................................................ 2213
P. Nodal Results ......................................................................................................................... 2214
P. Beam Results ......................................................................................................................... 2214
Chapter 9: General Engineering Theory

G.1 Input Generation
G.2 Types of Structures
G.3 Unit Systems
G.4 Coordinate Systems and Structure Geometry
  G.4.1 Global Coordinate System
  G.4.2 Local Coordinate System
  G.4.3 Relationship Between Global and Local Coordinates
G.5 Finite Element Information
  G.5.1 Plate and Shell Elements
  G.5.2 Solid Elements
  G.5.3 Surface Elements (Deprecated)
G.6 Member Properties
  G.6.1 Prismatic Properties
  G.6.2 Built-In Steel Section Libraries
  G.6.3 User-Provided Steel Table
  G.6.4 Tapered Sections
  G.6.5 Assign Command
  G.6.6 Steel Joist and Joist Girders
  G.6.7 Composite Beams and Composite Decks
  G.6.8 Curved Members
G.7 Member and Element Release
G.8 Axial-Only Specifications
  G.8.1 Truss and Tension- or Compression-Only Members
  G.8.2 Cable Members
G.9 Connection Tags
G.11 Member Offsets
G.12 Material Properties
G.13 Supports
  G.9 Tension- and Compression- Only Springs
G.14 Rigid Diaphragms
G.15 Loads
  G.15.1 Joint Loads
  G.15.2 Member Load
  G.15.3 Area, One-way, and Floor Loads
  G.15.4 Fixed End Member Load
  G.15.5 Prestress and Poststress Member Load
  G.15.6 Temperature and Strain Load
  G.15.7 Support Displacement Loads

Getting Started

This help file is intended to guide users who are new to STAAD.Pro as well as experienced users who want specific information on the basics of using the program.

Start by reading through this section which contains basic information on getting STAAD.Pro running on your computer.

It is then strongly recommended that you work through all three of the tutorials. These contain step-by-step procedures of modeling, analysis, design, and post processing different structures.

Next, read through the frequently performed tasks to learn how to perform common operations in the program.

GS. Welcome to STAAD.Pro

The ultimate power tool for computerized structural engineering.

STAAD.Pro CONNECT Edition is the most popular structural engineering software product for 3D model generation, analysis and multi-material design. It has an intuitive, user-friendly GUI, visualization tools, powerful analysis and design facilities and seamless integration to several other modeling and design software products. The software is fully compatible with supported Windows operating systems.

For static or dynamic analysis of bridges, containment structures, embedded structures (tunnels and culverts), pipe racks, steel, concrete, aluminum or timber buildings, transmission towers, stadiums or any other simple or complex structure, STAAD.Pro has been the choice of design professionals around the world for their specific analysis needs.

To see the new features in STAAD.Pro, please read the release report, which is also included as the What’s New? section in the online help.

GS. Overview of the STAAD.Pro Environment

Tip: Click on any label in the figure to jump to that section of the help.
Getting Started
GS. About STAAD.Pro Documentation

The documentation for STAAD.Pro consists of the following sections that make up the online help.
All the manuals can be accessed from the Help facilities of STAAD.Pro.

Getting Started (GS.)

This section contains information on the contents of the STAAD.Pro package, computer system requirements, installation process, copy protection issues and a description on how to run the programs in the package.

What's New?

This section contains the software release report for STAAD.Pro contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 06.
Tutorials (T.)

Tutorials that provide detailed and step-by-step explanation on using the programs are also provided.

Modeling (M.)

This section describes how to model structural elements and loads in STAAD.Pro using the Analytical Modeling workflow.

Analysis (A.)

This section of the help describes the analysis methods, data print commands, and how to perform analysis in STAAD.Pro.

Design (D.)

This section describes how to perform the design of structural elements using STAAD.Pro.

This section contains information on the various concrete, steel, timber, and aluminum design codes that are implemented in STAAD.Pro.

Postprocessing and Reports (P.)

This section describes how to review output, perform post-processing tasks, generate reports, and plot from STAAD.Pro.

Data Files and Interoperability (I.)

This section describes how to manually edit STAAD.Pro input files, import and export data, and interact with STAAD.Pro using external applications.

General Engineering Theory (G.)

This section deals with the theory behind the engineering calculations made by the STAAD engine.

Technical Reference of STAAD Commands (TR.)

This section includes an explanation of the commands available in the STAAD command file.

Ribbon Control Reference

This section describes the tools found in the ribbon toolbars.

Verification Examples (V.)

This section includes examples of STAAD.Pro example models along side reference ("textbook") examples or a set of “hand” calculations. This provides you with validation of standard program calculations.
Application Examples (EX.)

This section includes examples of various problems that can be solved using the STAAD engine. The examples represent various structural analysis and design problems commonly encountered by structural engineers. Additional example models installed with the product are described here in brief.

OpenSTAAD (OS.)

This section describes the application programming interface for STAAD.Pro.

GS. Using Online Help

The Web help opens in your default web browser.

The Help window consists of two panes — the navigation pane on the left and the topic pane on the right.

The navigation pane has the following tabs:

- Contents — used for browsing topics.
- Index — index of help content.
- Glossary — glossary of the help content.
- Search — displays the search results.
- Tool Index — index of the tools.

Hypertext links, which appear in color and are underlined when you hover the pointer over them, let you move easily between related topics.

**Note:** In case you are not able to view the Web help properly in Internet Explorer, make sure you turn off the Enable Protected Mode check box in the Security tab of the Internet Options dialog.

**Note:** The text size in the topic pane on the right is controlled by your web browser. To learn how to change the web page’s text size, consult the web browser’s Help file.

To open the Help window

1. Either:

   Click the Help tool in the top, right corner of the application window

   or

   Press <F1>

   The Help window opens and the Contents tab is displayed.

The Help window consists of two panes — the navigation pane on the left and the topic pane on the right. At the top of the topic pane is a topic banner containing additional navigation tools.
To browse topics using the Contents tab

1. On the Contents tab, click the symbol preceding any link to expand its contents.
2. Continue expanding folders until you reach the desired topic.
3. Select a topic to display its content in the topic pane.

To display the next or previous topic according to the topic order shown in the Contents tab

1. Either:
   - View...  
     Select...  
     the next topic  
     click the right arrow in the help window’s control bar
   - the previous topic  
     click the left arrow in the help window’s control bar

To navigate in this manner, it is not necessary to first select the Contents tab.

To use the index to find help content

1. Select the Index tab.
2. Scroll through the index using the scroll bar to find a specific entry.

   Tip: Press <Ctrl+F> to use your web browser’s find feature to locate instances of a word or phrase in the index.

3. Select the desired entry.
   The content that the selected index entry is referencing displays in the topic pane.

To search for text in the help content

1. In the Enter search terms field, type the word or phrase for which you are searching.
2. Either:
   - Click Search
   - or
   - Press <Enter>
   Results of the search display on the Search tab.
3. Click the title of any search result.
4. (Optional) Search for a term within a topic:
   a. Press <Ctrl+F>
      Your browser’s search dialog opens.
   b. Type the word or phrase for which you are searching.
   c. Click Next to find each occurrence of the text in this topic.

Search results vary based on the quality of the search criteria entered in the Search field. The more specific the search criteria, the more narrow the search results. You can improve your search results by improving the
search criteria. For example, a word is considered to be a group of contiguous alphanumeric characters. A phrase is a group of words and their punctuation. A search string is a word or phrase on which you search.

**GS. Documentation Conventions**

A number of typographical conventions are maintained throughout Bentley documentation, which makes it easier to identify and understand the information presented.

**Notes, Hints, and Warnings**

Items of special note are indicated as follows:

- **Note**: This is an item of general importance.
- **Tip**: This is optional time-saving information.
- **Warning**: This is information about actions that should not be performed under normal operating conditions.

**File Path/File Name.extension**

A fixed width typeface is used to indicate file names, file paths, and file extensions (e.g., `.../STAAD/Staadpro.exe`).

**Interface Control**

A bold typeface is used to indicate user controls, such as ribbon tabs, tool names, and dialog controls. (e.g., **File > Save As**).

**User Input**

A bold, fixed width typeface is used to indicate information which must be manually entered. (e.g., Type **DEAD LOAD** as the title for Load Case 1).

### Terminology

- **Click** - This refers to the action of pressing a mouse button. When not specified, click means to press the left mouse button.
- **Select** - Synonymous with Click. Used when referring to an action in a menu, drop-down list, list box, or other control where multiple options are available to you.
- **pop-up menu** - A pop-up menu is displayed typically with a right-click of the mouse on an item in the interface.
- **Window** - Describes an on screen element which may be manipulated independently. Multiple windows may be open and interacted with simultaneously.
- **Dialog** - This is an on screen element which (typically) must be interacted with before returning to the main window.
- **Cursor** - Various selection tools are referred to as “cursors” in STAAD.Pro. Selecting one of these tools will change the mouse pointer icon to reflect the current selection mode.

### Mathematical Notation

Similar to spelling conventions, American mathematical notation is used throughout the documentation. A serif typeface is typically used to clarify numbers or letters which might otherwise appear similar.

- Numbers greater than 999 are written using a comma (,) to separate every three digits.
  
  For example, the U.S. value of Young's Modulus is taken as 29,000,000 psi.

**Warning**: Do not use commas or spaces to separate digits within a number in a STAAD input file.
• Numbers with decimal fractions are written with a period to separate whole and fraction parts. For example, a beam with a length of 21.75 feet.
• Multiplication is represented with a raised – or middle– dot (·) or a multiplication symbol (×). For example, \( P = F \cdot A \) or \( P = F \times A \).
• Operation separators are used in the following order:
  1. parenthesis ( )
  2. square brackets [ ]
  3. curly brackets (i.e., braces) { }

For example,

\[
F_a = [1 - (Kl/r)^2/(2 \cdot C_c^2)]F_y / \{5/3 + [3(Kl/r)/(8 \cdot C_c)] - [(Kl/r)^3/(8 \cdot C_c^3)]\}
\]

Which may also be represented as:

\[
F_a = \frac{1 - \left(\frac{Kl}{r}\right)^2}{2C_c^2} F_y \left\{ \frac{5}{3} + \frac{3\left(\frac{Kl}{r}\right)}{8C_c} - \left(\frac{\left(\frac{Kl}{r}\right)^3}{8C_c^3}\right) \right\}
\]

GS. Where are the old manuals?

For many versions of STAAD.Pro, the help was primarily a collection of the user manuals in an online format. Though the organization has changed somewhat, all of the existing content is still available to you.

This chapters of this document have been separated into the logical portions of this help file. You can find each of the sections as follows:

1. “General Description” - General Engineering Theory (on page 2294)
2. “American Steel Design” - D1. American Codes (on page 1366)
3. “American Concrete Design” - D1.F. American Codes - Concrete Design per ACI 318 (on page 1478)
5. “Commands and Input Instructions” - Technical Reference of STAAD Commands (on page 2404)

International Design Codes Manual

This content is included in the D. Design Codes (on page 1366) section of the online help.

The American codes are now included here for consistency. The sections including American aluminium design, American transmission tower design, API steel design code, ANSI/AISC N690 design, and ASME NF codes have all been moved to the chapter for American design codes as well.

Release Report

This document is included as the What’s New? (on page 84) section of the online help.
Getting Started

This document has been reorganized and is included primarily within the Getting Started section of the online help.

Graphical User Interface

This content is no longer collected into a sub-section, but has been expanded to cover modeling, analysis, design, post-processing, and interoperability as described elsewhere in the online help.

Examples Manual

Most complete input examples, verification examples, and extended modeling examples have been collected into the Application Examples section of the help.

GS. About STAAD.Pro

STAAD.Pro is a general purpose structural analysis and design program with applications primarily in the building industry — commercial buildings, bridges and highway structures, industrial structures, chemical plant structures, dams, retaining walls, turbine foundations, culverts and other embedded structures, etc. The program hence consists of the following facilities to enable this task.

1. Graphical model generation utilities as well as text editor based commands for creating the mathematical model. Beam and column members are represented using lines. Walls, slabs and panel type entities are represented using triangular and quadrilateral finite elements. Solid blocks are represented using brick elements. These utilities allow you to create the geometry, assign properties, orient cross sections as desired, assign materials like steel, concrete, timber, aluminum, specify supports, apply loads explicitly as well as have the program generate loads, design parameters etc.

2. Analysis engines for performing linear elastic and p-delta analysis, finite element analysis, frequency extraction, and dynamic response (spectrum, time history, steady state, etc.).

4. Result viewing, result verification and report generation tools for examining displacement diagrams, bending moment and shear force diagrams, beam, plate and solid stress contours, etc.

5. Peripheral tools for activities like import and export of data from and to other widely accepted formats, links with other popular software programs for niche areas like reinforced and prestressed concrete slab design, footing design, steel connection design, etc.

6. A library of exposed functions called OpenSTAAD which allows you to access the internal functions and routines in STAAD.Pro as well as its graphical commands to tap into STAAD.Pro’s database and link input and output data to third-party software written using languages like C, C++, VB, VBA, FORTRAN, Java, Delphi, etc. Thus, OpenSTAAD can be used to link in-house or third-party applications with STAAD.Pro.

GS. System Requirements

The following hardware requirements are suggested minimums. Systems with increased capacity provide enhanced performance.
### Processor
Intel® Pentium or AMD® processor 3.0 GHz or greater.

### Memory
1 GB minimum, 2 GB recommended (4GB for STAAD.Pro Advanced). More memory almost always improves performance, particularly when working with larger models. 4 GB (8 GB for STAAD.Pro Advanced) or more can help speed up solutions for very large complex models with large numbers of load cases.

### Video
Graphics card supported by OpenGL. See the graphics card manufacturer for latest information on graphics drivers. 256 MB of video RAM or higher is recommended. If insufficient video RAM or no graphics card supported by OpenGL can be found, the application will attempt to use software emulation. For optimal performance, graphics display color depth should be set to 24-bit or higher. When using a color depth setting of 16-bit, some inconsistencies will be noted.

### Screen Resolution
A minimum screen resolution of 1280x1024 is required, but higher is recommended.

### Hard Disk
Requirements will vary depending on the modules you are installing. A typical minimum is 500 MB free space.
**Supported Operating Systems**

- Windows 10 (64-bit) - Home, Pro, Enterprise, and Education
- Windows 8.1 (64-bit) - Standard, Pro, and Enterprise
- Windows 7 SP1 (64-bit) - Home Basic, Home Premium, Professional, Enterprise, and Ultimate

**Note:** Windows 7 operating system is supported only if you have its service pack (SP1) installed.

**Note:** You must have the following Microsoft updates installed on your machine:

- KB4340917 - For Windows 10 Version 1803 Builds prior to 10.0.17134.191. The changes in KB4340917 are built into the August 2018 monthly update of Windows 10.
- KB2999226 - For Windows 7 SP1, Windows 8.1, Windows Server 2008 R2 SP1, and Windows Server 2012
- KB2999226 - For Windows 8.1 (64bit)
- KB2919355 - For Windows 8.1 and Windows Server 2012

Bentley does not support its software running on Microsoft operating systems versions that Microsoft has "retired". For more information on Microsoft's application retirement policy, click [here](#). For similar information on Bentley products, refer to the [Bentley Product Support](#) article.

Additional RAM, disk space, and video memory will enhance the performance of STAAD.Pro.

The minimum amount of physical + virtual memory required by the program is over 600MB. You may need to ensure that adequate amounts of virtual memory are available and that parameters such as paging file sizes should be large enough or span over multiple drives if the free space on any one drive runs low.

Another issue to keep in mind is the location of the TEMP parameter as in the SET TEMP environment variable in Windows. While performing calculations, depending on the structure size, the program may create very large scratch files which are placed in the folder location associated with the TEMP parameter. You may want to point the SET TEMP variable to a folder on a drive that has disk space sufficiently large to accommodate the requirements for large size structures.

You should have a basic familiarity with Microsoft® Windows® systems in order to use the software.

### GS. Installation and Licensing

For details on installation and licensing of this product, please refer to the [product Readme file](#), which is installed in the same location as the product and this help file.
GS. Limits on Models

The following limits to model size are effective for STAAD.Pro CONNECT Edition (release 21.00.00) and later.

- Joint number 1 to 999,999
- Number of joints: 200,000*
- Member/Element numbers: 1 to 999,999
- Number of Members, Plates, and Solids: 225,000*
- Load Case numbers: 1 to 99,999
- Number of primary and combination cases: 10,101
- Number of modes and frequencies: 2,700
- Number of load cases that may be combined by a Repeat Load or Load Combination command: 550

* Some STAAD copies are available with much smaller limits, please check what limits you have purchased.

Notes:

The numerical limits should be considered as upper limits built into the software for those quantities on an individual basis. In practice, the actual maximums the program can handle are determined by the hardware resources as well as the limits imposed by the operating system. For example, it is highly improbable that a single model with 999,999 members and 99,999 load cases can be solved.

The memory demand of the program is determined by the combined effect of two or more of these terms. For example, when a steel design is performed, the memory required depends on the product of the members being designed (NMD) as well as the number of load cases being designed for (NL). That is, NMD × NL. So the smaller the NMD, the larger the NL capacity and vice versa.

Experience has shown that for a medium size model of 5,000 frame members, about 1,500 load cases is the practical limit of what can be run for the 32-bit program on a computer with 16 GB RAM and 200 GB of free disk space.

GS. Fundamentals

This section introduces you to some of the fundamental concepts necessary for using STAAD.Pro. You are strongly encouraged to review this section to gain a firm understanding of the core concepts of the program.

GS. Starting STAAD.Pro

1. Start STAAD.Pro by one of the following methods:
   double-click the STAAD.Pro CONNECT Edition icon on your desktop
or
click the Windows Start button and then select **Bentley Engineering > STAAD.Pro CONNECT Edition V22**
or
in the program group, select the STAAD.Pro icon.
or
in Windows Explorer, double-click a STAAD.Pro file (with the file extension .std)
or
in Windows Explorer, double-click the icon for STAADPro.exe.

**Note:** Until you have activated a license for the program, it will remain in Limited mode and only function for 15 minutes before shutting down the application.

The **STAAD.Pro License Information** dialog opens.

2. (Optional) To configure the license for this session:
   a. Click
      The **STAAD.Pro License Information** dialog opens.
b. Select the **Product Type** and any **Additional Licenses** you need to use for this session.

Please refer to the product ReadMe or click the **Help with license selection** link for additional details.

c. Click **Accept**.

The STAAD.Pro window opens to the Start page.

3. Click **Continue**.

The STAAD.Pro window opens to the Start page.

**Related Links**

- *GS. STAAD.Pro License Configuration dialog* (on page 53)
- *GS. STAAD.Pro License Configuration dialog* (on page 53)

**GS. To create a new STAAD.Pro model**

To create a new STAAD.Pro model, use the following procedure.

1. On the Start page, select **New**.

   The **New** page opens to the **Model Info** tab.

2. Enter a **File Name**.

3. Specify a **Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.

4. Select the **Type** of model.

   This option selects the modeling method you want to use:
Analytical  For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.

Physical  For creating a model using the STAAD.Pro Physical Modeler interface.

Building  For creating a building model structure using the Building workflow.

5. Select the system of **Units**.

- **English**  English Imperial units: feet, pounds, seconds
- **Metric**  System International units: meters, kilograms, seconds

**Tip:** The units can be changed later if necessary, at any stage of the model creation.

6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.

7. Click **Create**.

The new STAAD.Pro model is opened in either the Analytical Modeling workflow, STAAD.Pro Physical Modeler, or the Building workflow based on your selection.

**Related Links**
- **GS. Start Page** (on page 50)
- **ProjectWise Project Association** (on page 2273)

**GS. To open a STAAD.Pro model**

To open an existing STAAD.Pro model, use the following procedure.

1. On the Start page, select **Open**.
   The New page opens to the **Recent** tab.
   Recently opened models are organized by the following categories:
   - Analytical
   - Physical
   - ProjectWise
   - Archive
   - All

2. Either:
   - select a recently used model from one of these tabs
   - or
   - select **Open Other Models** to search for a STAAD input file
   - or
   - select either **Sample Models** or **Verification Models** to open the example models which are installed with the program
If you select a recent model, it will open. If you select to browse for a model, an **Open** dialog opens.

3. In the Open dialog, navigate to and select a STAAD.Pro file (file extension *.std*) and then click **Open**.

The selected file opens.

If the STAAD.Pro file does not have a ProjectWise Project associated with it, then you will be prompted to select one.

**Related Links**
- *GS. Start Page* (on page 50)
- *ProjectWise Project Association* (on page 2273)

**GS. Workflows in STAAD.Pro**

The program is organized to reflect the typical process of modeling, analyzing, and post-processing for a structure.

A workflow in STAAD.Pro groups all of the common tasks associated with a major stage of your structural project.

**Overview of Workflows**

<table>
<thead>
<tr>
<th>Workflows</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Analytical Modeling</strong></td>
<td>used to model your structure using analytical objects</td>
</tr>
<tr>
<td><strong>Physical Modeling</strong></td>
<td>opens the STAAD.Pro Physical Modeler application, which is used to model using physical objects which will be subsequently decomposed into analytical objects when exported back into the STAAD.Pro interface</td>
</tr>
<tr>
<td><strong>Building Planner</strong></td>
<td>used to generate concrete building models with the integrated STAAD Building Planner interface</td>
</tr>
<tr>
<td><strong>Piping</strong></td>
<td>used to import piping support geometry and reactions from Bentley AutoPIPE</td>
</tr>
<tr>
<td><strong>Bridge Deck</strong></td>
<td>generating loads for use in the analysis of bridge structures</td>
</tr>
<tr>

<tr>
<td>Earthquake</td>
<td>this postprocessing workflow is used to check if the structure conforms to the basic geometric recommendations made in Eurocode 8 (EC8).</td>
</tr>
</tbody>
</table>

**Tip:** Once you are familiar with the Workflows, you can free up some screen area by unpinning the Workflows panel from the program window. It will then collapse to a tab on the left side of the application window. You can expand the panel by clicking on the tab to display the workflows when needed.
Where did the Modes and Page Controls go?

In previous generations of STAAD.Pro, a series of page controls were listed vertically along the left side of the view window. A series of operation modes were listed along the top of the view window (and also accessed via the Modes menu).

These modes have now been replaced by the Workflows panel. Similarly, the page controls are available for the current workflow just below the ribbon bar. These are now organized in a single row, rather than the former groupings.

GS. Selecting Objects in STAAD.Pro

With even relatively small structural models containing many nodes, beams, plates, loads, and other model objects, it is important that you be able to select the correct objects for assigning parameters. STAAD.Pro has a variety of tools to allow you to select objects by type, filter, boolean logic, and more.

In certain modes of selection, objects are chosen by clicking on their entry in a list. For selecting more than one object, press and hold <Ctrl> while clicking.

Selection Method

STAAD.Pro allows you to select one of several methods for graphical selection. These are described in the table below.

To choose a different the selection method, either:

- Select it from the Select ribbon tab in the Modes group, or
- right-click in the view window and select Selection Mode from the pop-up menu.
<table>
<thead>
<tr>
<th>Selection Type</th>
<th>Description</th>

<td><img src="image4.png" alt="Image" /></td>
<td>&lt;Ctrl+Shift+F3&gt;</td>
</tr>
</tbody>
</table>
### GS. Units in STAAD.Pro

STAAD.Pro uses a set of base units, called current units, for all input and output. The Current Units can be changed at any time to simplify entering input or interpreting results. The current input units are set using the **Set Current Input Units** dialog.

**Tip:** There are several instances in the program where the Current Units cannot be changed, such as when an input dialog is open. In this case, you can use the `<F2>` key to input different units.

STAAD.Pro also includes an extensive unit conversion utility.

### Display Units

STAAD.Pro can use a different set of units for displaying values in the active view window. These are controlled through several tabs on the **Options** dialog.

### Base Unit System

There are two base unit systems in the program which control the units (i.e., length, force, temperature, etc.) in which, values, specifically results and other information presented in the tables and reports, are displayed in. The base unit system also dictates what type of default values the program will use when attributes such as Modulus of Elasticity, Density, etc., are assigned based on material types - Steel, Concrete, Aluminum - selected from the program’s library (Please refer to [Technical Reference of STAAD Commands](on page 2404) for details). These two unit systems are:

- English (Foot, Pound, etc.) and
- Metric (KN, Meter, etc.)

**Tip:** If you recall, one of the choices made at the time of installing STAAD.Pro is this base unit system setting. That choice will serve as the default until you specifically change it.
Selecting Different Input Units in Dialogs

While you may typically wish to work in one unit system - or even with a specific unit of force or length, it is not uncommon to use a different unit for input. STAAD.Pro allows for the input of a value in any unit in most dialog boxes. This avoids the need to manually change the unit before and after adding a command or to convert a unit to something less commonly used. A unit is entered in the most convenient format and then converted to the current units for you. This is especially useful when adding or editing loads, where the current input units cannot be changed.

GS. To change the system units

There are two base unit systems in the program which control the units (length, force, temperature, etc.) in which values — specifically results and other information presented in the tables and report — are displayed. The base unit system also dictates what type of default values the program uses when attributes such as Modulus of Elasticity, Density, etc., are assigned based on material types (i.e., steel, Concrete, Aluminum) selected from the program’s library (Please refer to Built-In Material Constants (on page 2506)). These two unit systems are English (Foot, Pound, etc.) and Metric (KN, Meter, etc.).

1. On the Start page, click Configure.

The Configure Program dialog opens.

2. Select appropriate system of units in the Base Unit group on the General.
3. Click OK.

Related Links

- TR.26.2 Specifying Constants for Members and Elements (on page 2503)
- GS. Application Configuration dialog (on page 55)

GS. To set the current input units

To change the current length and force units for inputs, use the following procedure.

The current input units used for creating the model and assigning attributes such as properties, offsets, loads, etc. can be changed to use convenient units.

1. On the Geometry ribbon tab, select the Input Units tool in the Structure group.

The Set Input Units pop-up opens.
2. Select the base system of **Input Units**:

   - **English**
   - or
   - **Metric**
   - or
   - **Custom** - to mix different systems of units

3. Select a unit for **Length** on the left and unit for **Force** on the right.

4. Click **Apply**.

**GS. To convert units within a dialog field**

To input a unit different than the current unit within a dialog field, use the following procedure.

1. Click within a field that takes a dimensional value as input.

2. Press `<F2>`.

   A pop-up dialog opens to allow you to input values in any dimensionally correct unit.

3. (Optional) Press `<Ctrl+Q>` to open a list of dimensionally correct units and select one to populate this pop-up dialog.

4. Type the value in the known units.

   **Tip:** Values can also be input using a fractional system (e.g., 5 7/8”).

5. Once you are finished entering the units, press `<Return>`. The unit is converted into the Current Unit system.
GS. STAAD.Pro Converter utility

An extensive unit converter is included with the program which can convert values from one unit system to another.

Opens when the Unit Converter tool is selected from the Tools group on the Utilities ribbon tab.

Tools

<table>
<thead>
<tr>
<th>Tool icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image.png" alt="Custom" /></td>
<td>Click to add a custom unit conversion to the current unit category. In the Custom Units table, type a From unit label, the conversion Factor, and a To unit label and then click Ok. For example, you can type the following to add yards to the Length conversion:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>From</th>
<th>Factor</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Feet</td>
<td>3</td>

<td>Set the number of items to display in the recently used items list.</td>
</tr>
<tr>
<td><strong>Top Most</strong></td>
<td>Check this settings to keep the <strong>Unit Converter</strong> dialog on top of all other windows on your screen, even when other windows are active.</td>
</tr>
</tbody>
</table>

### GS. Coordinates in STAAD.Pro

STAAD.Pro Physical Modeler uses a conventional Cartesian coordinate system, with the global Y axis assumed as vertical (i.e., "Y up", or the height of the structure is parallel to the global Y axis).

**Global Coordinate System**

This coordinate system is a rectangular coordinate system (X, Y, Z) which follows the orthogonal "right hand" rule. This coordinate system may be used to define the joint locations and loading directions. The translational degrees of freedom are denoted by u1, u2, & u3 and the rotational degrees of freedom are denoted by u4, u5, & u6.
Local Coordinates

Each member or surface has its own local Cartesian coordinate system which is also oriented using the “right hand” rule.

The longitudinal axis of a member is the first axis, with the positive axis taken from the i to the j ends (i.e., Ni and Nj). The second axis is the oriented such that the 1-2 plane is then parallel to the global Y axis. The third axis is then normal to the first and second local axes as defined by the right hand rule. The local 2 and 3 axes coincide with the two principle moments of inertia of the cross-section. In the special case of a vertical member (where the local 1 axis is parallel to the global Y axis; i.e., a column), the local 3 axis is then made parallel to the global Z axis and the 2 axis is oriented respectively.

For surfaces, the local x axis is aligned with the edge defined by the first two nodes of the surface (i.e., N1 and N2). The program then calculates the area of each triangle formed by any other nodes to determine the largest
area. This triangle determines the plane of the surface and the local y axis lies perpendicular to the x axis within this plane. The third axis is then orthogonal to the surface as defined by the “right hand” rule.

![Figure 3: Local coordinates of a surface](image)

**GS. To use Z as the vertical axis**

To re-orient the global axis so that Z is vertical, use the following procedure.

You must close any open STAAD.Pro models in order change program configuration.

![Y as vertical](image)  ![Z as vertical](image)

**Note:** Both options follow the “right hand rule.”

*Figure 4: Global axis orientation options in STAAD.Pro*

**Important:** Not all STAAD.Pro features are compatible with Z UP orientation. Refer to [SET { Y | Z } UP](on page 2418) for additional details.

1. On the Start page, select **Configure**.
   The Application Configuration dialog opens.
2. On the **General** tab, select **Z up** in the Global Axis group.
3. Click **OK**.
New models will use the Z up orientation of the global axis.

**Tip:** You can repeat this procedure except to select Y up to return to set Y as vertical.

Any input files which have the `SET Z UP` command will automatically use this orientation.

**GS. Load Types in STAAD.Pro**

Several load cases may be created for a structure and each load case may contain several individual load specifications. Load cases may also be created by combining several existing load cases. A load case consisting of explicitly defined loads is called a Primary Load Case. A load case which combines the results of previously defined cases is called a Combination Load Case.

**Tip:** Here, we wish to introduce you to some of the load terminology and types used in STAAD.Pro. These concepts are critical in understanding how to correctly model loads on a structure.

**Primary Load Cases**

A primary load case is a set of explicitly defined loads, presumably from the same physical source, which will be passed to the analysis engine during the analysis of the model. Each of these explicitly defined loads is referred to as a Load Item.

In the STAAD input file, a primary load case is indicated by the `LOAD n` command.

Refer to [TR.32 Loading Specifications](on page 2650) for details.

Some examples of where a primary load case would be used are:

- All dead load on a structure.
- The reducible live load on an office building.
- The easterly wind load.
- The dead and live composite load on a pedestrian bridge.
- The superimposed dead load on a post-tensioned floor.

**Load Combinations**

A load combination is a set of load results which are combined algebraically to produce a superimposed set of results for post-processing. Therefore, a load combination instructs the program to take the results of previously solved primary load cases, factor them appropriately, and combine the values using Algebraic, SRSS or Absolute methods.

In the STAAD input file, a load combination is indicated by the `LOAD COMBINATION n` command.

Refer to [TR.35 Load Combination Specification](on page 2791) for details.
Reference Loads

Large models can include multiple load cases which do not require analysis in their own right and are simply the building blocks for inclusion in primary load cases. Reference Loads may be defined for this purpose. This is similar to a Repeat Load command, but has the added benefit of not being solved in its own right.

This converts a real load case to something similar to a load case definition. A reference load case is solved only when it is later called in a load case. The benefit is that it enables you to define as many load cases as you wish, but instruct the program to actually solve only a limited number of “real” load cases, thus limiting the amount of results to be examined.

Refer to TR.33 Reference Load Cases - Application (on page 2789) for details.

Notional Loads

A number of design codes require that a notional load be considered. Typically, this is defined lateral load equal to a percentage of the gravity loads. STAAD.Pro uses a feature similar to a the Repeat Load, but one that Primary and /or Reference load cases can be selected and a percentage of them can be applied in the appropriate global direction at each framing level.

These lateral loads are a requirement for some design codes (e.g., AISC 360-10).

Refer to TR.32.14 Notional Loads (on page 2785) for details.

Load Lists

A load list is primarily used to specify a list of existing load cases and load combinations to be used for subsequent processes, such as design, printing, etc.

Refer to TR.39 Load List Specification (on page 2836) for details.

Load Envelopes

Load Envelopes are a means for clustering a set of load cases under a single moniker (number). If one or more tasks have to be performed for a set of load cases (such as, serviceability checks under steel design for one set of load cases, strength checks under steel design for another set of cases, etc.) this feature is convenient.

This is an alternative to Load Lists, and is primarily used in post-processing and design. Load Envelopes also have keyword types which identify their intended use in design.

Refer to TR.40 Load Envelope (on page 2837) for details.

Load Definitions

Definitions contain the options you use to define data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases, snow load cases, and time history load cases.

Refer to TR.31 Definition of Load Systems (on page 2540) for details.
GS. STAAD Input Files

A STAAD model consists of a data file made up of simple, English-language like commands, using a format native to STAAD.Pro. This file specifies all input, analysis, and output commands used to inform the STAAD engine as to the geometry of the structural model, loads acting on this model, and instructs the engine on the analysis and design operations to be performed.

There are two methods for building a model and assigning the structure data using STAAD.Pro:

a. using the graphical model generation, or
b. directly editing the command input file using the STAAD.Pro Editor

The graphical method of creation (a) involves using either the Analytical Modeling or Physical Modeling workflow to draw the model using the graphical tools, and assigning data such as properties, material constants, loads, etc., using the various tools and dialog boxes of that mode. In this approach, the command file is automatically created by the program while you work. The input command file is updated whenever your structure is saved.

The direct editing method (b) involves creating or editing the command input file (file extension .std) directly using the STAAD Editor utility. These commands are explained in detail in Technical Reference of STAAD Commands (on page 2404) and several examples which illustrate this method are provided in the Application Examples (on page 4309).

**Tip:** The command input file is a plain text file so you can use any plain text editing software you prefer. However, it is recommended you use the STAAD.Pro Editor as this program contains tools such as Intellisense to complete commands and syntax checking.

**Tip:** For a hands on illustration of both these methods, it is recommend that you take a look at the Tutorials (on page 373).

Regardless of the means used to create the STAAD input file, once the model is ready for analysis, you will use the graphical environment to initiate analysis, review the analysis and/or design output data, and perform advanced design operations.

GS. Object Properties Inspection

You can inspect the properties and results of most analytical and physical model objects by double-clicking them in the view window.

The dialog that opens reflects the type of object selected as well as the assigned specifications, properties, available analysis and design results, etc.

8. **GS. Data Area** (on page 61)
9. **GS. Status Bar** (on page 78)
10. **GS. View Window** (on page 61)

**GS. Start Page**

The start page is displayed when STAAD.Pro opens or there is no model currently open.
Open tab

Used to open an existing STAAD input file or Archive. You can also open STAAD projects from a ProjectWise data source.

Select the Recent tab to view recent files by type. Hover your mouse pointer over any file to display the file and CONNECT Project properties.

The Additional License options are available here to allow you to select which license options you want to use before opening a file.

**Tip:** If you hover your mouse pointer over any item in the recent files list, you will see several tool icons on the right-hand side:

- **Pint to list** – pin this project to the top of the list
- **Remove from list** – remove this project from the list
- **Open Containing Folder** – open the folder where the project is saved in Windows Explorer

New tab

Used to create a new STAAD project. Options are available to start with an analytical model, a physical model, or in STAAD Building Planner.

The Additional License options are available here to allow you to select which license options you want to use before creating a file.

Archive tab

Used to create or extract STAAD.Pro archive files.
Share tab

Table 1: Share menu items

GS. **STAAD.Pro License Configuration** dialog

Used to manage license options for STAAD.Pro.

Opens when you select **License** from the Start page menu.
**Product Type**
Select the primary license to use for the application here.

- **STAAD.Pro** – using this license you will have access to the primary features and capabilities available in STAAD.Pro, including all design codes
- **STAAD.Pro Advanced** – The extends the basic STAAD.Pro application with additional capabilities such as an eigen-based advanced buckling analysis, geometric non-linear analysis, and other advanced analysis methods, a faster analysis solver, and access to advanced concrete design using RCDC.

**Primary Licenses**
This displays the status of each license type associated with your account.

**Additional License**
Select additional licenses to use:

- Structural SELECT Entitlements
- STAAD.Beava (Bridge Codes)
- RAM Connection
- Nuclear Design Codes

**Product Activation Wizard**
Opens the CONNECT License Client Activation window, which is used to activate or to reserve a license.

**License Management Tool**
Opens the Bentley Licensing Tool window, which is used to manage your current license entitlements, managed reserved licenses, and review the status of product licenses available to you.

**Help with license selection**
Click to open the latest details on license selection information on Bentley Communities.
Accept
Save the changes to the license configuration and close the dialog.

Exit
Close the dialog without saving any changes to the license configuration.

• GS. Starting STAAD.Pro (on page 31)
• GS. Starting STAAD.Pro (on page 31)

GS. Application Configuration dialog
Used to set program-wide parameters for STAAD.Pro.
Opens when Configure is selected on the application Start page.

General tab
Language
Select the user interface language from the drop-down list. You must restart the program to see that language used in user interface.

Base Unit
There are two base unit systems in the program which control the units (length, force, temperature, etc.) in which, values – specifically results and other information presented in the tables and reports – are displayed. The base unit system also dictates what type of default values the program will use when attributes such as Modulus of Elasticity, Density, etc., are assigned based on material types – Steel, Concrete, Aluminum – selected from the program's library. These two unit systems are English (Foot, Pound, etc.) and Metric (KN, Meter, etc.)

Global Axis
Select which axis represents the gravity direction in your model by default. Subsequently all modeling, analysis, and post-processing items would be based on this coordinate system.

Select either the Y up or Z up option.

Note: Some features in STAAD.Pro require that Y up be used for the global axis orientation.

Diagram Background
Select either a White or Black background for the view window. This selection will also set some default colors in which beams, plates and solids are drawn. For example, a white background is accompanied by black lines for drawing beams.

Theme
Select the basic color theme used in the application.

Options tab
Additional Options
Always Save Auxiliary Data
During the course of performing analysis, design, and post-processing operations, multiple files associated with a STAAD project are generated. Set this option to direct the program to save all files in the STAAD project when the project is closed.

Always Delete Results Data If Out of Sync
Set this option to delete results files when a project is opened if the input file has been modified more recently than those input files. This option is helpful in ensuring that results invalidated by recent changes to the input file will not be used in error.
Warn if model accessed from Network Drive
Set this option to display a warning dialog when an input file is opened from a network drive. Using a network drive can dramatically slow performance. It is recommended that local copies of files be made to improve performance.

Remove Bentley (B) logo from Report
Set this option to remove the Bentley logo from reports generated in STAAD.Pro.

**Tip:** You can always add a custom logo and branding to your reports.

**Startup Options**

Show Licensing Information
Check this option during the application launch to be prompted with License Information dialog (see [GS. Starting STAAD.Pro](#) on page 31) listing enabled licensing options.

Show CONNECT Advisor
Check this option to open the CONNECT Advisor window when the program starts.

Show news feed for new posts
Check this option to open the news feed reader when the program starts.

**File Format tab**

**Input format**

Single Line Format
Select whether Joint coordinates as well as Member, Plate, and Solid incidences will be written one per input line or multiple per input line by setting the associated options here.

Write expanded list
Set this option to instruct the program to write out joint, member or element numbers individually, for example: 1 2 3 4 5 instead of 1 TO 5 and consequently, creates voluminous input.

Joint Coordinate Significant Figures
Specify the number of significant digits used for nodal coordinates. This is used for models which require a high degree of precision.

**Output format**

Add key file information
Set this option to instruct the program to list all the key files that were used with the analysis including the date of the principal files.

**Note:** Even if the general case is that the Key Information is displayed, it can be turned off in a particular analysis if the data file contains the command SET NOFILE.

**Error format**

Create Error File
You may choose not to have the error file created at all, though this isn’t advisable. Un-check the box provided for that purpose if you choose to do so.

Log maximum errors per single input
A single line of input may contain more than one error. We can set how many such errors we want shown for each input line.

Log maximum errors
You can also set the maximum number of errors you want reported for the entire file. That number is 100 by default.
Design Codes tab

STAAD.Pro supports several major international design codes. Select the default design code to use when selecting the material-based design in the program.

**Note:** You may not use more than one design code in one single run, even if the Input Command File has more than one `CODE` command. Also note the design code specified by the Design Code tab must match that specified in the Input Command File.

| Command File Editor | Opens the current input command file (file extension .std) in the STAAD.Pro Editor. If any change has been made in the structure that has not been saved, you are prompted to save the structure first.  
**Note:** Refer to the [STAAD.Pro Editor help](#) (on page 2251) for additional assistance. |          |
| STAAD Output        | Opens the results of a successful Analysis and Design run in the STAAD.Pro Editor window.                                                                                                                    |          |

**GS. Tool Search**

You can search for any tool by typing part of the name in the Search field.

**Tip:** Hover your mouse pointer over any search result to see the location of the tool in each workflow, ribbon tab, and group.

In the search results drop-down, click **Show Details** to display the tool tip description for each tool in the results list.
GS. Page Control

Within each workflow, there are a series of Pages available which layout the order of that workflow. Though not required, it is recommended to work from left to right along the pages within any workflow.

**Tip:** If you close some of the dialogs for a page and need to display them again, simply click the **Restore View** tool (±) on the right-hand side of the page control bar.

### Menu item | Description
--- | ---
**Geometry** | Used to graphically select nodes, members and elements of the structure simultaneously. To select nodes, members or elements using the Geometry Cursor, simply click on the desired structural components. To select multiple nodes, members and elements, hold `<Ctrl>` while selecting. We may also select the structural components graphically by creating a window on screen with the cursor around these components.

**Physical Member** | Used in Steel Design or Concrete Design to graphically select all those beams defined as a same member in the member set up of member design, simultaneously. Members may be user defined or may be generated automatically using the Auto Form Member tool. To select all the beams defined as a same member using the Member Cursor, just click on one beam. The other beams having the same member name as the selected one will automatically be selected. To select multiple physical members, hold down `<Ctrl>` while selecting. You may also select the physical members graphically by dragging a fence area around these physical members using the cursor.

**Selection Mode >** | Drag Box | Click to activate the drag box selection mode.
Drag Line | Click to activate the drag line selection mode.
Region | Click to activate the region selection mode.

**Take Picture** | Used to take a snapshot image of current view. The picture is automatically added to a picture album.

**Add Beam** | Used to add beam by clicking start and end nodes.

**Tables** | Opens the **Tables** dialog, which is used to display and close different tables, such as Node coordinates, Beam incidences, Node displacements, etc. irrespective of the current page.

**Connection Tags >** | View Connection Tags | Opens the **Assign Connection Tags** dialog.
Check Connection Tags | (Active only after a successful analysis has been performed) Opens the **Assign Connection Tags** dialog and **Check Connection Tags** dialog, the latter of which is used to check the load case results from the analysis against the defined connection capacities in the Connection Tags XML data file.

**Open View** | Opens the **Open View** dialog, which is used to open a previously saved structural view window.
### Menu item | Description
---|---

<tr>
<td><strong>Solid Tools &gt;</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Check for Solids with Negative Volume (Jacobian)</strong></td>
<td>Used to verify that the solid elements in their model have the proper sequence (order) of node numbering to prevent warnings in the output file of solids containing negative volumes.</td>
</tr>
<tr>
<td><strong>Check for Warped Solids</strong></td>
<td>Used to check if a solid element is warped. Warped solids cannot be analyzed and will produce errors in the output file.</td>
</tr>
</tbody>
</table>
### Tool Name | Description
--- | ---

**Physical Member Restraints** | Used to automatically generate top and bottom flange restraint conditions for the selected physical members.

*Note:* The PBRACE command generated by this menu item is valid only for [Member Design](on page 1649) per AS 4100-1998 (Australian) steel design.

When selected, the program will search through all the nodes along the Physical Member and determine if any other beam is connected besides the beams in the current physical member definition. If another beam is present, a full restraint is placed on both the flanges. Otherwise, an unrestrained condition is imposed on both the flanges.

**Groups** | Opens the [Create Group](dialog, which is used to cluster a set of joints, beams, plates or solids into a single entity identified by a distinct name.

*Note:* If no groups exist, you will be prompted to create a group using the [Define Group Name](dialog.

Forums

http://communities.bentley.com/products/structural/structural_analysis___design/f/5932 — Post questions in the Bentley Communities forums to receive help and advice from fellow users and members of Bentley’s product support groups.

Nuclear Safety Related Features

An installation of STAAD.Pro provides users with an extensive set of features and capabilities. It is recognized that STAAD.Pro can be used on projects that require the highest level of safety such as nuclear power stations. Therefore, a set of key features as listed below have been defined as “Nuclear Safety Related Features.” For any user who has signed up to the QA&R program, any serious defect discovered in any of these features in a build of STAAD.Pro supplied as part of the QA&R that is determined to be of Critical or High Severity, will be notified as per the reporting requirements.

Models must be defined using the default axis system (Y-up) and the following capabilities are identified as being safety related.

1. Static Analysis
   a. first order elastic analysis
   b. P-Delta analysis
2. Dynamic Analysis
3. Features related to application of general loadings applied at/on nodes, members, plates and solids.
4. Features related to application of local boundary conditions (e.g., member releases, offsets etc.)
5. Features related to application of global boundary conditions (e.g., fixed, pinned, fixed but, spring supports)
6. Automated load generation features as per US codes (e.g., ASCE, IBC, UBC) such as:
   a. Wind load generation per ASCE 7
   b. Seismic load generation
   c. Response spectrum load generation
   d. Moving load generation

Design Codes:
1. The following STAAD command file driven Steel design are available:
   a. AISC 360-2016
   b. AISC 360-2010
   c. AISC 360-2005
   f. AISC N690 1984 and 1994 with Supplements S1 and S2
   h. CAN/CSA S16-14
   i. CAN/CSA S16-09

2. The following STAAD command file driven Concrete design are available:

Note that any other features, such as the graphical user interface and interfaces to link to external applications such as AutoPipe, RAM Connection, RAM Concept etc. are not considered as “Nuclear Safety Related Features” of the product/program.
The Software Release Report for STAAD.Pro contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 06. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

STAAD.Pro CONNECT Edition V22

CONNECT Edition V22 Update 1

The Software Release Report for STAAD.Pro CONNECT Edition V22 Update 1 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition V22 (release 22.00). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.01.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 22.01.00-1.1 Reduced Section Properties per IS1893 2016

IS1893 2016 Clause 6.4.3 calls for a reduction of moment of inertia values by 0.35 for beams and 0.7 for columns of concrete members only while analyzing the structure for static seismic and response spectrum/linear dynamic analysis. STAAD.Pro now includes a code-specific option for reduced section properties of concrete members which will automatically generate a separate stiffness matrix for these IS1893 2016 load cases. For all other load cases, the analysis will be performed using the unreduced stiffness matrix.

You may use this feature by either selecting the new Code Specific option and then selecting IS1893 2016 as the code in the Member Specification dialog Property Reduction Factors tab. You can manually enter the command using the MEMBER CRACKED CODE IS1893 2016 command.

Note: Automated stiffness reduction analysis is not supported by the basic solver. STAAD.Pro Advanced is required for this feature.

Using the code-specific member reduction properties helps by automating the analysis for when reduced section properties are required by the IS1893 2016 code. A separate stiffness matrix is produced using the reduced stiffness values for use with load cases containing IS1893 2016 static seismic and response spectrum loads. The unreduced stiffness matrix is then used for all other load cases.
The prime advantage of this feature is that this analysis is completely automated once the reduction factors are defined. Previously, in order to comply with the IS1893 2016 Clause 6.4.3 provision, you would have to specify reduced section properties for members, analyze the structure for only the IS1893 2016 seismic load cases, then use a CHANGE command to reset the stiffness reduction factors back to unity, and then re-analyze the structure for the remaining load cases. Care had to be taken that only concrete members had the reduction factor applied, as the global MEMBER CRACKED command can be applied to any member. For large models with hundreds and thousands of members and hundreds of load cases, the implementation of clause 6.4.3 using the previous reduction command would be very cumbersome.

Use of the code-specific reduction factors automates the analysis procedure. These reduction factors are only applied to concrete members with the member list or member groups (non-concrete members are ignored for this command). The separate stiffness matrix is automatically created using these reduction factors for use with IS1893 2016 seismic loads only while the unreduced stiffness matrix is used for all other load cases. No re-analysis or change commands are required.

- Member Specification dialog (on page 2962)
- TR.20.10 Member Property Reduction Factors (on page 2485)
- M. To assign cracked section properties to a member (on page 802)

RR 22.01.00-1.2 Import General Sections from Section Wizard

General shapes can now be imported from Section Wizard for use in the program.

Note: This profile shape should consist of only an outer contour. Any internal voids such as internal contours or openings will be ignored, though section properties calculated by Section Wizard based on sections with voids will be used.

Tip: Changing the structure diagram to display 3D rendering types for Full Sections or Sections Outline will display the shape profile. Similarly, 3D renderings of the structure will also display the shape profile.
RR 22.01.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 22.01.00-2.1 Physical Modeler Static Seismic Loads

STAAD.Pro Physical Modeler can now generate static (equivalent lateral force) seismic load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using static seismic loads.

RR 22.01.00-2.2 Physical Modeler Response Spectra Loads

STAAD.Pro Physical Modeler can now generate response spectra load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using response spectrum loads.
RR 22.01.00-2.3 Physical Modeler Time History Loads

STAAD.Pro Physical Modeler can now generate time history load cases for use directly in the Analytical Modeling workflow.

Refer to the STAAD.Pro Physical Modeler help for additional details on using time history loads.

RR 22.01.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 22.01.00-3.1 Static Seismic Loads per IBC 2018 / ASCE 7-16

Automatically generated equivalent lateral seismic loads per IBC 2018 / ASCE 7-16 are now available in STAAD.Pro.

The load parameters are assigned using the User Interface or can be manually entered in the STAAD editor.

Automatic load combinations using the tables from IBC 2018 can be added using the Auto Load Combination dialog (on page 3033), as well.

Changes from IBC 2015/ASCE 7-10 Code

The changes in seismic provisions of IBC 2018/ASCE 7-16 over the previous version IBC 2015/ASCE 7-10 are mainly observed in Mapped Spectral Acceleration parameters outlined in chapter 22. STAAD.Pro uses the spectral acceleration data in text format available in USGS site https://earthquake.usgs.gov/hazards/designmaps/datasets/. As the IBC 2018/ASCE 7-16 version of the data is not available, IBC 2012/ASCE 7-10 data in text format is used in the IBC 2018/ASCE 7-16 implementation.

The other significant change in the seismic provisions are in long-period site coefficient, $F_a$, and short-period site coefficient, $F_v$. Table 11.4-1 and 11.4-2 of the code provides the value of $F_a$ and $F_v$ respectively. These values are used for the IBC 2018 implementation in STAAD.Pro.

Note: Other changes to this portion of the code from the previous edition are not relevant to the calculations performed by STAAD.Pro.

Related Links
- TR.31.2.15 IBC 2018 Seismic Load Definition (on page 2603)

RR 22.01.00-3.2 IS 801 Cold-Formed Steel Design

The design of cold-formed steel members per the IS 801 code is again available in STAAD.Pro.

RR 22.01.00-3.3 IS 1893 2016 Seismic Irregularities Checks

STAAD.Pro can now check for vertical and plan irregularities per the IS 1893 2016 code for structures with defined rigid floor diaphragms.

Note: The program can additionally check for soft stories per the IS 1893 2016 code.

Horizontal irregularities (torsional and reentrant corners) per Table 5 and vertical irregularities (mass irregularities and irregular modes of oscillation) per Table 6 of IS 1893 2016 can be checked by the program using this command.
**Example Output**

RR 22.01.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 22.01.00-4.1 Steel AutoDrafter Workflow

The Steel AutoDrafter can now open any drawing directly within MicroStation.

Note: If you have MicroStation PowerDraft installed instead of MicroStation, you will have that product’s icon instead of the MicroStation icon in the drawing toolbar.

Related Links

- To open a drawing in MicroStation (on page 2235)

RR 22.04.00-4.2 RAM Connection Workflow Update

RAM Connection CONNECT Edition V13.0 is now supported in STAAD.Pro CONNECT Edition.

- Now compatible with versions of RAM Connection CONNECT Edition up through release 13.0 (CONNECT Edition V13).
- Connection Design per the AS4100 1998 (Australian) code
CONNECT Edition V22

The Software Release Report for STAAD.Pro CONNECT Edition V22 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition Update 3 (release 21.03). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 22.00.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

**Related Links**
- [GS. STAAD.Pro License Configuration dialog](on page 53)
- [GS. Starting STAAD.Pro](on page 31)

**RR 22.00.00-1.1 CONNECT Licensing**

STAAD.Pro now uses Bentley’s CONNECT License system, Bentley’s new process for product activation and usage tracking, improving our licensing capabilities with features such as:

- License alert notifications when you are approaching a custom usage threshold
- Replacing site activation keys with user validation, enhancing security around your Bentley licenses and subscriptions

With traditional SELECT Licensing, product activation has been through an activation key that an Organization distributed to all users. With CONNECT Licensing, product activation is managed by user sign in through the CONNECTION Client, which is installed on each machine that uses Bentley applications. This offers a more secure and manageable system as it offers usage alerts, notifying your users when they are about to reach a certain usage limit set by the Administrator.

Detailed information is available at Bentley Communities Licensing and Activation Wiki: [https://communities.bentley.com/products/licensing/w/licensing_wiki/37813/connect-licensing](https://communities.bentley.com/products/licensing/w/licensing_wiki/37813/connect-licensing) for detailed information.

STAAD.Pro CONNECT Edition

CONNECT Edition Update 3

The Software Release Report for STAAD.Pro CONNECT Edition Update 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition Update 2 (release 21.00.02). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.03.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 21.03.00-1.1 APL Apollo Structural Tube Sections

The catalog of available steel sections has been expanded to include the hollow sections from APL Apollo (India).

To specify an APL Apollo tube section

1. Select the Specifications ribbon tab.
2. On the Properties - Whole Structure dialog, click Section Database.
   
   The Section Profiles Table dialog opens.
3. Select APL Apollo Tubes in the list of tables on the Steel tab.
4. Select the profile type to use from the list of tables:
   
   Rectangular Hollow
   Square Hollow
   Circular Hollow
5. Select the profile from the Select Profile list.
6. (Optional) Check the Material option to specify the selected material with the profile.
7. Click Add.

The section is now added to the Section tab in the Properties - Whole Structure dialog box and can be assigned to members.

RR 21.03.00-1.2 Steel Grade A1085 Profiles in AISC 360-16 and 360-10

Steel pipes and tubes using A1085 grade material can now be designed using AISC 360-16 and AISC 360-10 design codes.

A new set of section tables are available in the American Steel Tables for HSS Rectangle and HSS Round shapes to make use of the A1085 steel grade. Sections using this steel grade have properties which use the full nominal wall thickness.

**Note:** Use of profiles from the A1085 steel tables will result in that material be used, regardless of the SGR parameter for AISC 360-16 or WTYP parameter for AISC 360-10.

RR 21.03.00-1.3 Inclined Loads Input via Create New Load Items Dialog

Inclined loads can now be easily added via the graphical user interface in the Create New Load Items dialog.

Previously, an inclined nodal load –that is a nodal load applied in coordinate system other than the global coordinate system– required editing the STAAD input file. These loads can now be applied by defining a reference node, relative reference point, or absolute reference point in the graphical user interface's Analytical Modeling workflow.

**Related Links**

RR 21.03.00-2 Features Affecting the Preprocessor

The following section describes the new features that have been added that affect the preprocessor section of the program, also known as the Analytical Modeling workflow and Physical Modeling workflow (or STAAD.Pro Physical Modeler).

RR 21.03.00-2.1 Physical Modeling Load Cases and Combinations

STAAD.Pro Physical Modeler can now generate load cases and combinations for use directly in the Analytical Modeling workflow.

RR 21.03.00-2.1 Physical Modeling Circular Openings

STAAD.Pro Physical Modeler can now model circular openings in surfaces with a defined radius.

RR 21.03.00-2.3 Physical Modeling Connection Tags

You can now assign connection tags from with STAAD.Pro Physical Modeler. These will be exported to the analytical model in STAAD.Pro as well as to a corresponding ISM repository.
RR 21.03.00-2.4 Miscellaneous Enhancements to the Physical Modeler

The following additional enhancements have been made to the STAAD.Pro Physical Modeler.

- A new file format is used. When opening a model created in a previous version of STAAD.Pro Physical Modeler, you will be prompted to save to the new format.
- New **Spreadsheet** and **Data** ribbon tabs have been added to make the spreadsheet controls consistent with other tools in the application. The **Spreadsheet** ribbon tab is used to select the current spreadsheet. The **Data** ribbon tab is used to perform actions on the current spreadsheet, view window, or output panel (similar to right-click pop-up menus in each of those respective application areas).
- The ISM workflow has been enhanced to place common settings in the program configuration. This helps to streamline ISM repository actions.

RR 21.03.00-2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10

Automatically generated equivalent lateral seismic loads per IBC 2015 / ASCE 7-10 are now available in STAAD.Pro.

The load parameters are assigned using the User Interface or can be manually entered in the STAAD editor. Automatic load combinations using the tables from IBC 2015 can be added using the **Auto Load Combination dialog** (on page 3033), as well.

• RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10 (on page 94)

RR 21.03.00-3.5 Soft Story Checks per IS 1893 2016

The check soft story option may be added to a floor diaphragm command set to check for soft stories per IS1893:2016. The previous (approximate) method for checking soft stories implemented for IS 1893 2002 has been deprecated in favor of a displacement-based approach using rigid diaphragms.

Soft story checking a process by which designers check stiffness of a story with that of the story above. If the stiffness of a story is lower than that of the story above, the story is considered as a Soft story. Having a soft story in the building makes that story venerable to Earthquake. As per the revised IS 1893 Part-1:2016, if a soft story is detected, structural configuration needs to be change with the introduction of additional lateral load resisting elements in the story detected as soft story. The previous version of IS 1893 Part-1, had provisions to increase design story shear in the soft story and increase percent of steel in the lateral load resisting elements in that soft story. This provision has been withheld in the present version of the code. This makes the situation a stringent one for the designer if a story is detected as a soft story.

Soft Story Checking

There was an approximate methodology available in STAAD.Pro. The program used to compute story stiffness of a story by summing up the lateral stiffness of columns and shear walls (modelled using surface elements). The stiffness of a column is calculated as $12EI / L^2$ where E is the Young's modulus, I is the moment of inertia and L is the length of the column respectively and that for a shear wall (without opening) is calculated as $P_3/3EI + 1.2P_3/h$ (i.e. summation of flexural stiffness and shear stiffness, obtained as deflection of a cantilever wall under a single lateral load P at its top) where h is the height, A is the cross-sectional area and G is the shear modulus of the wall (E and I carry usual meaning).

This method is approximate one and works in the presence of FLOOR HEIGHT commands. On studying the literatures available on this subject, this method proved to be approximate as it fails to capture actual story stiffness including the effect of bracings. Story stiffness should be computed using a displacement based approach. STAAD.Pro is currently equipped with the facility to consider the in-plane stiffness of slabs as Rigid Diaphragm. In STAAD.Pro lateral stiffness is calculated only when the floor is modeled as rigid floor diaphragm since it functions as transferring story shears and torsional moments to lateral force-resisting members during earthquake.

**Story Stiffness Computation Example**

Consider a multi-story building:
The points are master nodes. The story stiffness is defined as the inverse of inter-story drift when a unit load is applied at that story only.

The unit load applied is along X, Z and θY.

Consider the displacement of 2nd story. The displacements are:

Story 1: ΔX1, ΔZ1, θY1;
Story 2: ΔX2, ΔZ2, θY2

Relative Displacement for story 2 is:
RX2 = ΔX2 - ΔX1; RZ2 = ΔZ2 – ΔZ1; RθY2 = θY2 - θY1

Story Stiffness X = 1/((ΔX2 – ΔX1))
Story Stiffness Z = 1/((ΔZ2 – ΔZ1));
Story Stiffness θY = 1/((θY2 - θY1))

The rest is the same for all the other stories.

**Note:** This story stiffness is not the same as column story stiffness which is calculated as \((nCol \times 12EI/L3)\), \(n=\) number of columns.

**Command Input**

The story stiffness can be printed using the PRINT STORY STIFFNESS command.

If soft story check is required to be performed following commands are required to be defined immediately after rigid floor diaphragm is specified in the FLOOR DIAPHRAGM command.

CONNECT Edition Update 2

The Software Release Report for STAAD.Pro CONNECT Edition Update 2 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition Update 1 (release 21.00.01). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.00.02-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.
RR 21.00.02-1.1 Select ribbon tab

A new ribbon tab containing tools for selecting model objects has been added to several of the workflows. Having quick access to the selection tools on a single ribbon tab makes selecting objects and then further refining the selection set easier.

The Select ribbon tab is available in multiple workflows, so you no longer have to switch to the Analytical modeling workflow to change the object selection as required in some instances in previous releases.

Related Links

- Select tab (on page 2945)

RR 21.00.02-1.2 New Output Viewer

The STAAD.Pro Editor is now used to view the analysis results file in the Analytical modeling workflow. The updated editor is now used to navigate the results file (file extension .anl).

Related Links

- P. To view analysis results (on page 2212)

RR 21.00.02-2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.00.02-2.1 AISC 360-16

The program can now perform steel design of members per ANSI/AISC 360-16 Specifications for Structural Steel Buildings.

The seismic provisions of AISC 341-16 are also implemented.

Performance Enhancements - Design for CODE CHECK / MEMBER SELECT up to 20 times faster than AISC 360-10.

Detailed Design output - TRACK 0,1, & 2 reports improved to display more intermediate results.

AISC 360-16 Design

To use the 2016 edition, specify the command:

CODE AISC UNIFIED 2016

The checking or selection of members is performed per the following sections of AISC 360-16 and AISC 341-16:

- Section Classification: Chapter B
- Tension Chapter D
- Compression: Chapter E
- Flexure: Chapter F
- Shear: Chapter G
- Torsion (Including checks as per DG-9 for certain profile shapes – see below): Chapter H & Design Guide 9 for Torsion design
- Combined actions – Chapter H for:
  - Axial and/or
- Flexure and/or
- Shear and/or
- Torsion
- Checks for Seismic suitability – AISC 341-16

The following section profile shapes are allowed for design:

- Rolled Shapes
  - I-Shape
  - Channel
  - Single angle
  - Solid Circular bar
  - Solid Rectangular bar
  - Tee
  - HSS rectangular
  - HSS round
- Built Up Shapes
  - Built Up Channel
  - Built Up I
  - Double Channels – back to back
  - Double Channels – face to face
  - Double Angles
  - Built Up Box
  - I With Cover Plates (Top and/or bottom)
- Tapered Shapes
  - I with web tapered
  - Square hollow shape with wall tapered
  - Circular hollow shape diameter tapered

**Note:** Certain checks (e.g., DG-9 torsion checks) will only be performed for certain profile shapes (non-HSS shapes).

**RR 21.00.02-2.2 ACI 318-14**

The program can now design concrete columns and beams per ACI 318-14 *Building Code Requirements for Structural Concrete*. The following describes the code clauses from ACI 318-14 implemented for beams and columns.

**Note:** Plate elements and deep beams cannot be designed per ACI 318-14. Use an older edition of the ACI code to design these elements if needed.

**Materials**

- Beams
  
  19.2.2
  19.2.3.1
19.2.4.2

- Columns
  19.2.2
  19.2.4.2

**Minimum Reinforcement**

- Beams
  9.6.1.1
  9.6.1.2
  9.6.1.3
  9.7.2.1
  9.7.6.4.2
  9.7.6.4.3

- Columns
  10.6.1
  10.7.2.1
  10.7.3.1
  10.7.6.1
  10.7.6.2
  25.2.3

Clauses 9.7.6.4.2 and 9.7.6.4.3 are not included in the standard design criteria of the minimum reinforcement since the design of these criteria should consider the rebar including the bar detailing and thus they should be applied in a second design after performing the strength design and the bar detailing.

Clause 9.6.1.3 is also not included in the standard criteria since the reduction of the minimum reinforcement is optional.

**Service**

RR 21.00.02-2.3 Russian Wind Load per SP 20.13330.2016

Static and dynamic wind loads per the SP 20.13330.2016 SNiP 2.01.07-85 code can now be applied in STAAD.Pro.

In order to perform dynamic wind load generation in STAAD.Pro you must previously define a static load case. The static load case could be any primary static load case which is defined before the Russian dynamic load case, including a static wind loading per the same code. This static load case will provide static load vector to the dynamic wind load module.

As the Russian dynamic wind load component requires modal masses and eigen vectors to calculate the dynamic wind load component at nodes, modal analysis must be performed before the dynamic wind load definition. Therefore, you must also include a separate load case for modal analysis with reference mass defined before the load case. See G.17.3.2 Mass Modeling (on page 2365) for details. Alternatively, if the mass loads are not needed for use with other load cases (that is, a reference load case is not needed for other loads), then you may define the mass loads within the dynamic load case prior to the WIND LOAD command.

CONNECT Edition Update 1

The Software Release Report for STAAD.Pro CONNECT Edition Update 1 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro CONNECT Edition (release 21.00.00). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.
RR 21.00.01-1.1 Share to ProjectWise

You can now share a STAAD.Pro project directly to a ProjectWise data source. STAAD.Pro lets you select which files associated with the input (.std) file you want to include.

Related Links
- *I. To share a STAAD.Pro project in ProjectWise* (on page 2285)

RR 21.00.01-1.2 Quick Commands

Two new sets of quick commands have been added to the graphical view window to allow for quicker model navigation and modeling.

**Quick Navigation**

Press `<Shift>` when right-clicking in the view window to open the View ribbon tab Tools group and your mouse pointer location.

**Quick Commands**

Press the space bar when the view window has the application focus to open the Quick Commands menu. This customizable pop-up menu contains the following groups of tools:

- **Geometry** ribbon tab Selection group
- **View** ribbon tab Labels group
- **Loading** ribbon tab Display group
- **Utilities** ribbon tab Geometry Tools group
- **Utilities** ribbon tab Utilities group

You can customize the Quick Commands with any tool by clicking the icon and then adding tools from the Customize Quick Commands Popup dialog.
RR 21.00.01-2 Features Affecting the Preprocessor

This section describes features that have been added that affect the preprocessor section of the program, also known as the Modeling Mode.

RR 21.00.01-2.1 Ritz Vector Analysis with User-Defined Starting Load Vectors

You can now directly specify the starting load vectors for use with load dependant Ritz vector method for the eigen solution.

Related Links

- TR.31.9 Defining Starting Load (on page 2648)
- M. To use starting vectors with load-dependant Ritz vectors (on page 865)

RR 21.00.01-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

RR 21.00.01-3.1 AISC 360-16 Technical Preview

The program can now perform steel design of members per ANSI/AISC 360-16 Specifications for Structural Steel Buildings.

Note: This feature was released as Technical Preview. It has been released as a commercial feature in a more recent release.

Related Links

- D1.A. American Codes - Steel Design per AISC 360 Unified Specification (on page 1366)

CONNECT Edition

The Software Release Report for STAAD.Pro CONNECT Edition contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 6) (release 20.07.11). This document should be read in conjunction with all other STAAD.Pro help files, including the Revision History document.

RR 21.00.00-1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

RR 21.00.00-1.1 New User Interface

The STAAD.Pro user interface has been updated and refined.
**Ribbon Controls**

The menus and toolbars have been replaced with a series of tabbed toolbars along the top of the application window. These are context sensitive to the current "workflow" as well as to the current model selection. There are fewer tools displayed at one time, so they can be larger and thus easier to identify. However, the tools you need are always available by selecting the tab (similar to menus in a tradition Windows program).

The icons for the tools are updated to reflect a consistent theme, further making the correct tool easy to identify.

**Workflows Panel**

The system of application modes has been replaced with the Workflows panel.

**Tip:** Once you become familiar with the workflows, you can hide the panel to display a larger viewing area. Simply click the Workflow tab again to select a different workflow.

**Tip:** If you close some of the dialogs for a page and need to display them again, simply click the **Restore View** tool ( ) on the right-hand side of the page control bar.

**Page Control Bar**

The pages within each workflow have been streamlined from those in the previous modes. A single row of pages is displayed for the current workflow, just above the view window. Select the appropriate page for your current task to display the corresponding dialogs and tables.

**RR 21.00.00-1.2 CONNECT Advisor**

STAAD.Pro now includes Bentley's CONNECT Advisor, which allows you to search Communities, LEARN content, online videos, and more from one convenient window.

**Related Links**

- **Bentley CONNECT Advisor Dialog** (on page 2279)

**RR 21.00.00-1.3 64-bit Analysis Engine**

The STAAD analysis and design engine now utilizes a 64-bit solver.

This allows you to analyze larger, more complex models with more objects and load cases. The analysis engine is faster for models of all sizes.

**RR 21.00.00-1.4 Web Help**

The product documentation is now delivered as a browser-based "Web Help." The Web help opens in your default browser.

Refer to **GS. Using Online Help** (on page 24) for additional details on using Web Help.

**RR 21.00.00-1.5 STAAD.Pro Script Editor**

A new macro editor is available to create and edit custom scripts to extend STAAD.Pro.

You can launch the new STAAD.Pro Script Editor application by selecting the **Macro Editor** tool in the **Developer** group on the **Utilities** ribbon tab.
RR 21.00.00-2 Features Affecting the Preprocessor

This section describes features that have been added that affect the preprocessor section of the program, also known as the Modeling Mode.

RR 21.00.00-2.1 STAAD.Pro Physical Modeler

You can use physical modeling concepts to generate structure geometry and reference load cases through the STAAD.Pro Physical Modeler interface.

You can launch STAAD.Pro Physical Modeler by selecting this as the modeling method when creating a new model on the Start page or by selecting the Physical Modeling workflow for an empty model.

Notes:
- Syncing physical model data will overwrite any model geometry created in the analytical modeling interfaces (i.e., traditional STAAD.Pro user interface or STAAD.Pro Editor).
- You cannot edit geometry, materials, reference loads, etc. created in the physical modeling interface from either the STAAD.Pro user interface or the STAAD.Pro Editor. Physical models must be edited in STAAD.Pro Physical Modeler.
- It is recommended that you begin a physical model by selecting the Physical Modeler from the New Model Wizard.

The STAAD.Pro tutorials (on page 373) have been re-written to incorporate the physical modeling workflow. It is recommended that even experienced STAAD users work through these tutorials to familiarize themselves with STAAD.Pro Physical Modeler.

Similarly, take some time to review the Quick Overview and Getting Started sections of the STAAD.Pro Physical Modeler help as they describe many of the differences in working in STAAD.Pro Physical Modeler versus the traditional STAAD.Pro interface and STAAD input files.

RR 21.00.00-2.2 NBCC 2010 Seismic Load

The program can now generate seismic loads per the National Building Code of Canada, 2010 edition.

Both the equivalent lateral force method and seismic response spectra are now supported per the NRC 2010.

Related Links
- TR.31.2.4 Canadian Seismic Code (NRC) - 2010 (on page 2556)
- TR.32.10.1.3 Response Spectrum Specification per NRC 2010 (on page 2702)

RR 21.00.00-3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.
RR 21.00.00-3.1 NZS3404:1997 Steel Design

The program can now perform steel design per NZS3404: 1997 New Zealand Standard for Steel Structures, Parts 1 & 2, including Amendments 1 & 2.

Refer to D1.1.A. New Zealand Codes - Steel Design per NZS 3404-1997 (on page 2021) for details on this code implementation.

RR 21.00.00-3.2 ACI 318-14 Technical Preview

The program can now design concrete columns and beams per ACI 318-14 Building Code Requirements for Structural Concrete.

Note: This feature was released as Technical Preview. It has been released as a commercial feature in a more recent release.

Related Links

- D1.F.1 Design Operations (on page 1479)

RR 21.00.00-4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the post processing and interactive design workflows. These are explained in the following pages.

RR 21.00.00-4.1 RAM Connection Workflow Update

RAM Connection CONNECT Edition is now supported in STAAD.Pro CONNECT Edition.

- Connection Design per the IS800-2007(Indian) code

STAAD.Pro V8i

The Software Release Reports for STAAD.Pro V8i contain detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 03. These documents should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

V8i (SELECTseries 6)

The Software Release Report for STAAD.Pro V8i (SELECTseries 6) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 5) (release 20.07.10) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-11.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.
AD.2007-11.1.1 Mode Bar Reorganization

The modes in STAAD.Pro have been reorganized to reflect a linear workflow through modeling, postprocessing, and design stages of a project.

Note: This feature has been replaced by the Workflows feature with the CONNECT Edition Edition of STAAD.Pro.

Additionally, the tabs are color coded by group:

- Blue: preprocessing and modeling
- Light green: postprocessing
- Dark green: foundation design
- Yellow: steel design
- Red: concrete design
- Magenta: earthquake checks

AD.2007-11.1.2 Advanced Analysis Engine Enhancements

The advanced analysis engine has been completely reformatted with new routines to provide even faster methods to build and solve the stiffness matrix.

Arnoldi/Lanczos Eigen Method

In addition to the standard subspace iteration method for eigen solution, the Advanced Math Solver can use the Arnoldi/Lanczos method. For large scale eigen value problems, the Arnoldi method is very efficient.

Load Dependant Ritz Vectors

Ritz vector analysis can be used for dynamically loaded structures to more efficiently evaluate the relevant modes. It can require significantly less computational effort to evaluate a large structure when compared to natural free-vibration methods.
Autoshifting of Eigen Vectors

For subspace iteration and the Arnoldi/Lanczos methods, an autoshift option can be used to reduce memory demand for large structures.

Refer to G.17.3.1 Solution of the Eigenproblem (on page 2363) for details.

AD.2007-11.1.3* CONNECT Enabled

STAAD.Pro is now CONNECT Enabled. This means that you can associated your STAAD.Pro models with ProjectWise Projects from within the application to track application usage per project.

You must sign in with your Bentley CONNECT account. The Bentley CONNECTION Client is used to sign in and the status is displayed in the user icon in the top-right corner of the STAAD.Pro application window.

A new menu, Cloud Services, has been added which contains ProjectWise Project features, links to cloud portals, and a link to AD.2007-10.1.3* Scenario Services (on page 119).

Once you start a new model or open an existing model that is not yet associated with a ProjectWise Project, you will be prompted to assign a ProjectWise Project to your model. A list of all registered projects in your organization is displayed. You can also register new projects (Only users with Admin/Co-admin roles can register a project). STAAD.Pro will display the ProjectWise Project name in the Job Info dialog as well as in the window title bar.

Tip: As of CONNECT Edition, the Cloud Services tools can be found on the File ribbon tab in the Backstage.

For additional information on CONNECTED Projects, please see http://www.bentley.com/en-US/Promo/CONNECT/why+connect.htm.

Refer to Cloud Services tab (on page 2878) for details.

AD.2007-11.1.4† RAM Connection CONNECT Edition v11 Support

STAAD.Pro now supports RAM Connection CONNECT Edition (v11.0) and in the Connection Design workflow.
• STAAD.Pro is now compatible with versions of RAM Connection CONNECT Edition up through release 11.0. The following design codes are supported:
  
  • AISC 360-10 (LRFD and ASD)
  • GB 50017-2003 (China)
  • EN 1993-1-8 (Eurocode 3)
  
• You can export the Connection Design reports (on page 971) directly to a Microsoft® Office Word® document from the STAAD.Pro interface.

AD.2007-11.1.5† Connection Tags Enhancements

You can now assign user-defined equations for checking connection tags in STAAD.Pro. The XML Schema for the connection tag files has been updated. See “Connection Tags XML File Schema” (on page 986) in the User Interface help for details on the schema, as well as on using wildcards and created user-defined equations.

AD.2007-11.1.6† Add Member Enhancements

The Add Member functionality in the graphical user interface has been enhanced to facility the saving, loading, and managing of user-defined attribute sets.

Select Geometry > Add Beam > Set New Member Attributes to open the Define Member Attributes dialog (on page 2905). Here you can define the default attributes for various predefined attribute sets, as well as create user-defined attribute sets.

AD.2007-11.1.7† ISM Integration

STAAD.Pro is now capable of transferring data to and from v5 of Bentley's Integrated Structural Modeling technology by means of the StructLink utility.

ISM v5 includes support information, ProjectWise integration, and substructures. Refer to the ISM documentation for additional details.

AD.2007-11.2 Features Affecting the Preprocessor

This section describes features that have been added that affect the preprocessor section of the program, also known as the Modeling Mode.

AD.2007-11.2.1 Building Planner

This modeling tool allows you to rapidly generate concrete building structure models for analysis and design in STAAD.Pro and detailing in the RC Designer mode.

PlanWin and FrameWin have now been directly integrated into the STAAD.Pro user interface as the Building Planner mode.

Building Planner is primarily intended for design of concrete building structures for the Indian code.

Use of Building Planner is a separate license, which can be selected in the License Configuration section on the STAAD.Pro start page.

Refer to the Building Planner mode (on page 895) for details.
AD.2007-11.2.2 STAAD Editor

A new STAAD editor has been added which has advanced features for manually editing your STAAD input files, including IntelliSense.

Model Navigation

Associated commands are "blocked" together in the editor such that can be managed easier. Larger blocks can be collapsed to show only the first line/command, making it easier to navigate through large models.

A document outline of the model is also in a separate pane. You can double-click any entry in the outline to jump to that point in the input file.

IntelliSense

Intelligent code completion is now integrated into the STAAD editor. This allows context-aware code completion suggestions when you type in the editor.

Hover your mouse pointer over the suggested keywords to view tool tips for each.

Section profiles in standard tables are also linked to the editor. When entering a table shape, simply select it from the list of shapes in the drop-down list.

Enhanced Help

Press <F1> to view the help topic related to the command keyword from the Technical Reference help.

Refer to the STAAD Editor (on page 2251) help for details.

AD.2007-11.3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

Note: Items labeled with an obelisk (i.e., dagger) (†) were added or updated in the Service Pack 2 release of V8i (SELECTseries 6).

Note: Items labeled with a double obelisk (i.e., dagger) (††) were added or updated in the Service Pack 3 release of V8i (SELECTseries 6).
AD.2007-11.3.1 ACI 318-11 Concrete Design

Concrete design per the 2011 edition of the ACI 318 specification (ACI 318-11) is now available in STAAD.Pro. Several new parameters have been introduced to accommodate design of slender columns using the moment magnification procedure for sway and non-sway frames.

Refer to D1.F.5.6.1 Slenderness Effects and Analysis Consideration (on page 1521) for details.

To design concrete columns per ACI 318-11

The general outline of this procedure applies to designing all concrete members per ACI 318-11, but the specific parameters mentioned pertain only to the design of columns using the moment magnification method.

1. In the Modeling mode, select the Design | Concrete tab.

   The Concrete Design - Whole Structure dialog opens.

2. In the Current Code drop-down list, select ACI 318-11.

   This will insert the following commands into the STAAD.Pro input file:
   
   ```
   CODE ACI
   ```

3. Click Define Parameters.

   The Design Parameters dialog opens.

4. Select the MMAG parameter and type 0 for the option and then click Add.

   This instructs the program to use the detailed calculations considering sway or non-sway frames.

5. Select the SWY parameter and select the appropriate bracing condition for the frame containing the columns to be designed and then click Add.

6. (Optional) Set values for BDY, BDZ, SKY, SKZ, SLY, SLZ, SQY, SQZ, SWY, and TRN parameters as necessary (i.e., when the defaults to not match the column conditions).

7. Close the Design Parameters dialog and assign the parameters to the appropriate members.

   Tip: The parameters mentioned here are only applicable to columns. They will be ignored for beam members.

AD.2007-11.3.2 CAN/CSA S16-14 Steel Design

Steel design per the 2014 edition of the Canadian S16 code, Limit States Design of Steel Structures, is now available.

The performance of designs per CAN/CSA S16-09 has also been improved. The changes in code checks from the 09 and 14 edition of the codes are noted in D4.E.6.1 Members Subject to Axial Forces (on page 1730).

To specify a design using CAN/CSA-S16-14

1. Select the Design | Steel page.

   The Steel Design - Whole Structure dialog opens.

2. In the Current Code list, select the CAN/CSA-S16-14.

3. Click Define Parameters list.

   The Define Parameters dialog opens.

4. Specify one or more design parameters as necessary.
Note: Refer to the descriptions in the dialog or to D4.E.7 Design Parameters (on page 1736) for definitions of the design parameters and default values used.

5. Click Add.

This will insert the following commands into the STAAD input file:

```
CODE CANADIAN
```

Tip: To use the older edition of the Canadian steel design code, the command CODE CANADIAN 2009 is required.

AD.2007-11.3.3 SANS 10162-1:2011 Steel Design

Steel design per the South African SANS 10162-1:2011 code is now available.

Specifying a design using SANS 10162-1:2011

1. Select the Design | Steel page.
   
   The Steel Design - Whole Structure dialog opens.

2. In the Current Code list, select the SANS10162-1:2011.

3. Click Define Parameters list.

   The Define Parameters dialog opens.

4. Specify one or more design parameters as necessary.

   Note: Refer to the descriptions in the dialog or to D14.C.7 Design Parameters (on page 2207) for definitions of the design parameters and default values used.

5. Click Add.

   This will insert the following commands into the STAAD input file:

   ```
   CODE SANS10162-1:2011
   ```

   Tip: Alternately, SANS10162 will also use the latest edition. To use the older edition of the South African steel design code, SANS10162-1: 1993 is required.

Refer to D14.C. South African Codes - Steel Design Per SANS 10162-1:2011 (on page 2200) for details.

AD.2007-11.3.4 SP 63.13330-2012 Concrete Design

Concrete design per the Russian code SP 63.13330-2012 is now supported.

Refer to D13.D. Russian Codes - Concrete Design Per SP 63.1330.2012 (on page 2164) help for details.

AD.2007-11.3.5 AISC 360-05/10 Metric Steel Design

Steel design in metric per the AISC 360-05/10 code is now supported.

When you select metric units in STAAD.Pro, the full user interface (including section properties, results, etc.) displays the correct metric units for AISC 360-05/10 steel design. Additionally, the results are also fully in metric units.
AD.2007-11.3.6 AISC 360-05/10 Tapered Member Design

The design of tapered square and round tube shapes as well as tapered I-shaped members is now available per the AISC 360-10 code.

The design of tapered members was previously available under the AISC 360-05 code, but the performance of design per this code has also been enhanced. Refer to D1.A.5.7 Design of Web-Tapered Members (on page 1377) for details.

AD.2007-11.3.7 AISC 341-05/10 Seismic Provision Checks

Seismic provisions of AISC 341-05/10 can now be checked as part of an AISC 360-05/10 member design.

Several additional parameters have been added to the AISC 360 unified codes (both 2005 and 2010 editions) to check the additional seismic provisions of AISC 341. Refer to D1.A.9 Seismic Provision Checking per AISC 341 (on page 1388) for details.

AD.2007-11.3.8 IBC 2012 / ASCE 7-10 Seismic Loads

Automatically generated equivalent lateral seismic loads and response spectra per IBC 2012 / ASCE 7-10 are now available in STAAD.Pro.

The load parameters are assigned using the User Interface or can be manually entered in the STAAD editor. Automatic load combinations using the tables from IBC 2012 can be added using the Auto Load Combination dialog (on page 3033), as well.

To specify an IBC 2012/ASCE 7-10 static seismic load

1. Either:
   - Select Commands > Loading > Definitions > Seismic Load > IBC 2012 Load
   or
   - Select the Definitions section in the Load & Definitions dialog and then click Add.

   The Create New Definitions / Load Cases / Load Items dialog opens with the Add New Seismic Definitions dialog (on page 3044) tab selected.
2. Select IBC 2012 ASCE 7-10 in the Type drop-down list.

3. (Optional) Select the Include Accidental Load checkbox to consider accidental torsion.

4. Either:
   - Type a ZIP code
   - or
   - Type Latitude and Longitude values
   - or
   - Type Ss and S1 mapped values.

5. Specify the required seismic load parameters:
   - Type long-period transition time, TL, value in the indicated units.
   - Type an Importance factor (I) value,
   - Type Response Modification Factor X (RX) and Response Modification Factor Z (RZ) values, respectively.
   - Select the Site class (SCL) from the drop-down list.

6. (Optional) Specify the following optional seismic parameters as necessary:
a. Type short-period site coefficient, $F_a$, and long-period site coefficient, $F_v$, values, respectively.

**Note:** These values are required if Site class (SCL) of 6 is selected (corresponds to IBC 2012 site class of F).

b. Type a CT value used to calculate the time period.

c. Type the Period in X Direction (PX) and Period in Z Direction (PZ) values, respectively. Otherwise these values are calculated from the code.

d. Type an exponent value, $x$, for use in ASCE 7-10 equation 12.8-7.

7. Click Add.

The IBC 2012 parameters are added to the Seismic Definitions section of the Load & Definition dialog.

Refer to TR.31.2.13 IBC 2012 Seismic Load Definition (on page 2596) for details.

**AD.2007-11.3.9 Eurocode 3 Steel Grades**

SGR values now are aligned with Table 3.1: EN 1993-1-1: 2005.

SGR 3, 4 have been changed to represent S450 and S275 N/NL grades respectively.

**Related Links**

- [DS.C.6 Design Parameters](on page 1776)

**AD.2007-11.3.10 AIJ 2002 and 2005 New Design Parameters**

The following design parameters have been added or updated in the AIJ 2002 and 2005 design codes in STAAD.Pro.

- The MISES parameter now has an option to ignore torsion in the calculation of the Von Mises stresses.
- A new parameter, MBG, has been added to ignore the web of H-shape, I-shape, and channel sections in calculating the section modulus about the local Z axis.
- A new parameter, YNG, has been added to the AIJ 2002 implementation to instruct the design engine how to evaluate Young's Modulus, $E$.

Refer to the codes in [D9. Japanese Codes](on page 1969) help for details.

**AD.2007-11.3.11 Steel Design Code Performance Improvements**

Performance of steel design per CSA S16-509 and IS800:2007 codes has been improved.

**AD.2007-11.3.12† NRC 2005 Seismic Loads Updates and Additions**

Seismic loads per the National Building Code of Canada's NRC 2005 have been updated and expanded to include torsion in the static load equivalent method as well as response spectrum loading.

**AD.2007-11.3.13† IS 800 Design of Additional Steel Shapes**

The design of both double-channel face-to-face and I-sections with cover plates is now available per the IS 800 2007 specification.

Refer to “Assigning Properties from Steel Tables” (on page 2461) ” for details on assigning double-channel front-to-front sections (FR) and I-sections with top and bottom plates (TB).
AD.2007-11.3.14† AISC 360 Design of I-Sections with Cover Plates

The design of I-sections with cover plates is now available per the AISC 360 2005 and 2010 specifications. Refer to "Design of I-Section with Cover Plates" (on page 2461) for details on the assumptions and limit states used in the design of these sections. Refer to "Assigning Properties from Steel Tables" (on page 2461) for details on assigning I-sections with top and bottom plates (TB).

AD.2007-11.3.15† IS 800 Design Updates

The following additions and enhancements were added to steel design per the IS 800 2007 specification:

- Flexural-torsional buckling of single angles per Cl. 7.5.1.2.
- Minimum web thickness is checked against the serviceability requirements in Cl. 8.6.1.1 and the compression flange buckling requirement of Cl. 8.6.1.2.
- The various sections of Amendment-1 to the IS:800-2007 Code, dated January 2012, are implemented in STAAD.Pro as applicable.

AD.2007-11.3.16† Floor and One-Way Load Panel Information Printing

The program can now include floor load and one-way load panel information in the output (.ANL) file or in an external text file. Refer to the Create New Load Items dialog Floor Load tab (on page 3012) in the User Interface help for information on using this feature through the graphical user interface. Refer to TR.32.4 Area, One-way, and Floor Load Specifications (on page 2664) for information on the command input for this feature.

V8i (SELECTseries 5)

The Software Release Report for STAAD.Pro V8i (SELECTseries 5) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 4) (release 20.07.09). This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-10.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.
**AD.2007-10.1.1 Bentley Trust Licensing**

STAAD.Pro now utilizes Bentley’s Trust Licensing program.

This allows you or your organization the flexibility to utilize the program as needed without interruption, regardless of the availability of licenses. The usage data is collected periodically for billing at a later time for your convenience.

Refer to the *Getting Started & Troubleshooting Guide* (installed with STAAD.Pro) for additional information on license setup for STAAD.Pro.

Visit [Bentley.com](http://Bentley.com) for more information on Bentley’s licensing solutions.

**AD.2007-10.1.2 Brazilian Steel Databases**

Brazilian steel section databases have been added to the section profile tables included in STAAD.Pro.

To select a Brazilian steel profile shape

1. Select the **General | Property** page.
   
   The **Properties - Whole Structure** dialog opens.
2. Click **Section Database** on the **Properties - Whole Structure** dialog.
   
   The **Section Profile Table** dialog opens.
3. On the Steel tab, expand the **Brazilian** entry to select a shape class.
4. Select a shape and specify any shape parameters in the dialog.
5. Click **Add**.
   
   The section is added to the list on the **Properties - Whole Structure** dialog Section tab.

**AD.2007-10.1.3* Scenario Services**

STAAD.Pro projects can be run in Bentley’s Scenario Services (formerly ProjectWise Scenario Services or Bentley CONNECT Scenario Services) server with a SELECT account. This allows you to run large models or complex, nonlinear analyses in the “cloud,” leveraging extensive computing power. Additionally, STAAD.Pro models can be added Multiple Discipline Optimization (MDO) projects.
Refer to Cloud Services tab (on page 2878) for additional information on using this feature.

AD.2007-10.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

![STAAD Analysis and Design](image)

**Note:** Items labeled with an asterisk (*) were added or updated in the QA&R release of V8i (SELECTseries 5) (Build 20.07.10.XX).

AD.2007-10.2.1 Advanced Cable Analysis

An advanced, nonlinear cable analysis has been added to STAAD.Pro. The nonlinear nature of the static solver can utilize either the Newton-Rapshon method or a modified Newton-Raphson method for reduced computational effort. The cables are considered as geometrically nonlinear.

Refer to the following procedures:

- **M. To add a member specification** (on page 797)
- **A. To specify a nonlinear cable analysis** (on page 931)
- **A. To specify post-analysis print commands** (on page 939)

Refer to G.17.2.8 Advanced Nonlinear Cable Analysis (on page 2358) for details on the analysis methodology used by STAAD.Pro.

AD.2007-10.2.2 Colombian Seismic Code

Static lateral forces for seismic loads based on Reglamento Colombiano Sismo Resistente (NSR-10) (2010 edition of Colombian seismic code)

**Note:** Refer to TR.31.2.7 Colombian NSR-10 Seismic Load (on page 2573) for details on the command parameters.

AD.2007-10.2.3 Canadian Steel Code Update

Steel design CAN/CSA-S16-09, Design of Steel Structures, is now available in STAAD.Pro.

Refer to D4.E. Canadian Codes - Steel Design per CAN/CSA-S16-09/14 (on page 1728) for additional information.

To specify a design using CAN/CSA-S16-09

1. Select the Design | Steel page.
   - The Steel Design - Whole Structure dialog opens.
2. In the Current Code list, select the CAN/CSA-S16-09.
3. Click Define Parameters list. The Define Parameters dialog opens.
4. Specify one or more design parameters as necessary.

Note: Refer to the descriptions in the dialog or to D4.E.7 Design Parameters (on page 1736) for definitions of the design parameters and default values used.

5. Click Add.

This will insert the following commands into the STAAD input file:

```
CODE CANADIAN
```

Tip: To use the older edition of the Canadian steel design code, the command `CODE CANADIAN 2001` is required.

AD.2007-10.2.4 Eurocode 3 National Annexes

Two additional country’s National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: Germany and Sweden.

As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.

```
AD.2007-10.2.4.1 German National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the German NA to EC3, use the following procedure.
```

When the German National Annex to EC3 is used for design, the output section title is revised to include the German National Annex (National Annex to DIN EN 1993-1-1:2005). Additionally, the partial safety factors used are included in the output and are specified in the German NA.

For additional information, please refer to D5.D.12 German National Annex to EC3 (on page 1849) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754).

1. In the Modeling mode, select the Design | Steel tab.
   The Steel Design - Whole Structure dialog opens.
3. Click Define Parameters.
   The Design Parameters dialog opens.
4. Select the NA parameter in the list box.
5. Select the (10) Germany in the Select National Annex drop-down list.
6. Click Add.

   This will insert the following commands into the STAAD.Pro input file:

   CODE EN 1993-1-1:2005
   NA 10

AD.2007-10.2.4.2 Swedish National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Swedish NA to EC3, use the following procedure.

The Swedish National Annex document referred to is “BFS EN 1993-1-1:2005.”

When the Swedish National Annex to EC3 is used for design, the output section title is revised to include the Swedish National Annex (National Annex to EN 1993-1-1:2005). Additionally, the partial safety factors used are included in the output and are specified in the Swedish NA.

For additional information, please refer to D5.D.13 Swedish National Annex to EC3 (on page 1853) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754).

1. In the Modeling mode, select the Design | Steel tab.
   The Steel Design - Whole Structure dialog opens.
3. Click Define Parameters.
   The Design Parameters dialog opens.
4. Select the NA parameter in the list box.
5. Select the (11) Sweden in the Select National Annex drop-down list.
6. Click Add.

   This will insert the following commands into the STAAD.Pro input file:

   CODE EN 1993-1-1:2005
   NA 11

AD.2007-10.2.5 AISC 360-10 Torsion Design

STAAD.Pro can now design open shapes for stresses due to torsion per AISC Design Guide #9, Torsional Analysis of Structural Steel Members.
A new TORSION parameter for the AISC 360-10 steel design code which can be set to instruct the program to perform torsion checks per this guide.

Refer to D1.A.5.6 Design for Torsion (on page 1374) for details on the checks performed.

**To include torsion checks per Design Guide #9**

1. In the Modeling mode, select the Design | Steel tab.
   
   The Steel Design - Whole Structure dialog opens.

2. In the Current Code drop-down list, select AISC 360-10.

3. Click Define Parameters.
   
   The Design Parameters dialog opens.

4. Select the TORSION parameter and select 1 for the option.

5. (Optional) Select the TRACK parameter and select 3 for the option.
   
   This will include detailed output for the Design Guide #9 checks in the output.

6. Click Add.
   
   This will insert the following commands into the STAAD.Pro input file:

   ```plaintext
   CODE AISC UNIFIED 2010
   TORSION 1
   TRACK 3
   ```

7. For the TORSION parameter (and for the optional TRACK parameter), you must specify a member list using the assignment tools in the Steel Design - Whole Structure dialog.

**AD.2007-10.2.6 Missing Mass**

Missing mass can now be specified for time history load definitions.

Missing mass and rigid body modes are reported in the output and can be selected in the post-processing mode drop-down (* for mm & + for rb)

![Figure 6: Missing mass modes are marked with an (*) in the Modes drop-down list](image)
Rigid body modes are used internally to establish relative and absolute structure displacement, particularly for structures supported on relatively weak springs. Refer to TR.31.4 Definition of Time History Load (on page 2630) and TR.34.2 Modal Calculation Command (on page 2791) for additional information.

AD.2007-10.2.7* Wind Loads per Russian Design Code SP 20.13330.2011
Refer to TR.31.3 Definition of Wind Load (on page 2623) for additional information.

Refer to TR.32.10.1.12 Response Spectrum Specification per SP 14.13330.2011 (on page 2764) for additional information.

AD.2007-10.2.9* Steel Design per Russian Design Code SP 16.13330.2011
Steel member design per SP 16.13330.2011, Steel Structures, is now available in STAAD.Pro. Refer to D13.C. Russian Codes - Steel Design Per SP 16.13330.2011 (on page 2152) for additional information.

Specifying a design using SP 16.13330.2011

1. Select the Design | Steel page.
   The Steel Design - Whole Structure dialog opens.
3. Click Define Parameters list.
   The Define Parameters dialog opens.
4. Specify one or more design parameters as necessary.
   Note: Refer to the descriptions in the dialog or to D13.C.4 Design Parameters (on page 2156) for definitions of the design parameters and default values used.
5. Click Add.
   This will insert the following commands into the STAAD input file:
   CODE RUSSIAN
   Tip: To use the older edition of the Russian steel design code, the command CODE RUSSIAN 1990 is required.
6. Assign the code parameters to members as necessary.

AD.2007-10.3 Features Affecting Post Processing
The following new feature has been added and existing features have been modified in the Post Processing modes. These are explained in the following pages.

Note: Items labeled with an asterisk (*) were added or updated in the QA&R release of V8i (SELECTseries 5) (Build 20.07.10.XX).
AD.2007-10.3.1 RAM Connection Mode Update

RAM Connection V8i features are now supported in STAAD.Pro V8i (SELECTseries 5) RAM Connection mode.

- Now compatible with versions of RAM Connection V8i up through release 8.0 (SELECTseries 4).
- New templates:
  - US: MEP Knee BCF, Moment End Plate BCF, Moment End Plate BCW, Moment End Plate BS Apex, and Moment End Plate BS
  - UK: Bolted End Plate BS Apex
- New sections added to the RAM Connection database for connection design:
  - Canadian WS, MS, S, HP, Angel, Channel, MC Channel, and HSS Round shapes
  - Brazilian I, Angle, and Channel shapes

AD.2007-10.3.2* CAN/CSA-A23.3-10 in RC Designer

The RC Designer module (Concrete Design mode) can now be used to design beams and columns per CAN/CSA A23.3-10.

- Beam (on page 1021) and Column (on page 1024) design per CAN/CSA A23.3-10 – The design of concrete columns and beams per the Canadian concrete code is now supported.

V8i (SELECTseries 4)

The Software Release Report for STAAD.Pro V8i (SELECTseries 4) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 3) (release 20.07.08) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-09.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

Note: Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 4) (Build 20.07.09.22).

AD.2007-09.1.1 I-Section with Different Flange Shapes

User-provided steel table Wide Flange sections can now have different flange sizes on top and bottom.
Previously, the sections were required to be doubly symmetric. Now, you may specify a different bottom flange size.

To add a UPT I-Section with different flange sizes

1. (Optional) Select Tools > Select Input Units. Select appropriate units for length and click OK.
2. Select Tools > Create User Table.
   If no User Defined Table exists, you will be prompted to create one.
   The Create User Provided Table dialog opens.
3. Click New Table.
   The Select Section Type dialog opens.
4. In the Select Section Type list, select WIDE FLANGE and then click OK.
   Tip: You can also use this dialog to save the User Provided Table as a separate file.
   The dialog closes and the Select Existing Table list in the Create User Provided Table dialog now has at least one entry.
5. Click Add New Property.
   The Wide Flange dialog opens.
6. Type dimensions in the \textbf{D}, \textbf{TF}, \textbf{WF}, \textbf{TW}, \textbf{TF1}, and, \textbf{WF1} fields to define the section.

Two new fields— \textbf{TF1} and \textbf{WF1} —are used to specify different dimensions for the bottom flange. If these fields are left empty, the values for the top flange are used (doubly symmetric section).

\textbf{Note:} Refer to \textit{TR.19.1 Wide Flange} (on page 2449) for detailed descriptions on properties of Wide Flange sections in User Steel tables.

7. Click \textbf{Calculate}.

The derivative cross section properties are calculated.

8. Click \textbf{OK}.
The dialog closes and the section is added to the **Table Data** list in the **Create User Provided Table** dialog.

**AD.2007-09.1.2 I-Section with Flange Plates or Composite Slab**

User-provided steel table Wide Flange sections can now have an additional bottom flange plate or composite concrete on the top flange.

These options are available in the **Wide Flange** dialog in the user interface. The additional flange plates or composite slab data is then used along with the base section properties.

**To add a UPT I-Section with flange plates and composite slab**

1. (Optional) Select **Tools > Select Input Units**. Select appropriate units for length and click **OK**.
2. Select **Tools > Create User Table**.
   
   If no User Defined Table exists, you will be prompted to create one.

   The **Create User Provided Table** dialog opens.
3. Click **New Table**.
   
   The **Select Section Type** dialog opens.
4. In the **Select Section Type** list, select **WIDE FLANGE** and then click **OK**.

   **Tip:** You can also use this dialog to save the User Provided Table as a separate file.

   The dialog closes and the **Select Existing Table** list in the **Create User Provided Table** dialog now has at least one entry.
5. Click **Add New Property**.

   The **Wide Flange** dialog opens.
6. Add a composite flange:
   a. Check the option for **Additional Composite Flange**.
   b. Type dimensions in the **B(left), B(right), Thickness**, and, **Modular Ratio** fields to define the composite slab.

   **Note:** Refer to TR.19.1 Wide Flange (on page 2449) for detailed descriptions on properties of Wide Flange sections in User Steel tables.

7. To add a bottom cover plate, select the **Additional Bottom Steel Plate** option and type values for **B(left), B(right), and Thickness**.
Tip: Top cover plates cannot be added in association with a composite slab, only bottom cover plates.

8. Click Calculate.

The derivative cross section properties are calculated.

9. Click OK.

The dialog closes and the section is added to the Table Data list in the Create User Provided Table dialog.

AD.2007-09.1.3 ISM Integration

STAAD.Pro is now capable of transferring data to and from v3 of Bentley's Integrated Structural Modeling technology by means of the StructLink utility.

ISM v3 includes support for foundation information. STAAD Foundation Advanced is now ISM Enabled, so this allows for an improved method for transferring and updating support information for STAAD Foundation Advanced, as well as other ISM Enabled products using v3 of ISM, such as detailing products like ProConcrete.

AD.2007-09.1.4* Connection Tags

This feature is used to both create connection data within STAAD.Pro and to transfer it to other programs via the ISM link. This data can then be used in third-party programs, such as Tekla Structures®. The connections can then be checked against a defined capacity.

Connection tags are assigned and checked from within the STAAD.Pro User Interface by use of the right-click pop-up menu. When a beam member is selected (using the beam cursor), a sub-menu for Connection Tags is provided with tools for using connection tags.

Note: Refer to Connection Tags sub menu (on page 999) for additional information on using this feature.

Connection tags consist of two pieces of data:

i. A Connection Tags XML file, which contains the connection categories, tag names, and member end releases for the connection tag. Connection capacities are also specified for each combination of member and connecting member which may utilize a connection tag. Refer to Connection Tags XML File Schema (on page 986) for additional information on the required structure of this XML file.

ii. Assignments of connection tags to members are stored in the STAAD input file. Though this is done within the DEFINE MEMBER ATTRIBUTE command, it is strongly recommended that the user interface features be used to make connection tag assignments as these must utilize only the connection categories and tag names in the associated XML file. Refer to TR.29.2 Connection Tag Member Attribute (on page 2537) for additional information on this command.

AD.2007-09.2 Features Affecting the Pre-Processor

This section describes features that have been added that affect the pre-processor section of the program, also known as the Modeling Mode.

AD.2007-09.2.1 Print Center of Rigidity

The PRINT DIAPHRAGM CR command may be used to obtain a print-out of the center of rigidity and center of mass at each rigid diaphragm in the model.

The lateral force at each floor, as generated by earthquake and wind loading, acts at the center of rigidity of each floor which is modeled as rigid floor diaphragm. The center of mass of each floor is defined as the mean location
of the mass system of each floor. The mass of the floor is assumed to be concentrated at this point when the floor
is modeled as rigid diaphragm. The distance between these two is the lever arm for the natural torsion moment
for seismic loads when that option is used.

Related Links
- TR.42 Print Specifications (on page 2840)
- A. To output the center of rigidity (on page 940)

AD.2007-09.2.2 Load & Definition

A new feature has been added to include horizontal torsion for rigid floor diaphragms in the equivalent static
seismic analysis. This torsion—referred to as the natural torsion—accounts for the static eccentricity which is
the difference between center of mass and center of rigidity of a rigid floor diaphragm, to be used to multiply the
UBC, IBC, 1893, etc.

Refer to TR.32.12.2.1 Generation of Seismic Loads (on page 2773) for additional details.

Adding Natural Torsion factor to a static seismic load

The natural torsion factor is specified along with the accidental torsion factor.

1. Add a Seismic Load definition to your model.
2. Add a Load Case with the Loading Type of Seismic to your model.
3. Select the seismic load case in the Load & Definition dialog and click Add.
   The Add New: Load Items dialog opens.
4. Select the Seismic Loads tab.
5. Set the option to use the Multiplying factor for Natural Torsion Moment and type a value (less than or
equal to one).
6. Select the direction and specify the accidental torsion option as necessary.
7. Click Add.

**Related Links**
- **TR.32.12.2.1 Generation of Seismic Loads** (on page 2773)
- **TR.32.12.2.2 Generation of IS:1893 Seismic Load** (on page 2778)
- **M. To add a seismic load** (on page 842)

**AD.2007-09.2.3 Check for Soft Story**

The CHECK SOFT STORY option may be added to a FLOOR DIAPHRAGM command set to check for soft stories per either IS1893:2002 or ASCE7-95 codes.

Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command PRINT STORY STIFFNESS in the post analysis print commands section.

**Related Links**
- **Floor Diaphragm Options dialog** (on page 3079)
- **TR.28.2.1 Soft Story Checking** (on page 2529)
- **TR.28.2 Floor Diaphragm** (on page 2526)
- **TR.42 Print Specifications** (on page 2840)
- **A. To check for soft stories and seismic code irregularities** (on page 937)
AD.2007-09.2.4 Check Story Drift

The PRINT STORY DRIFT command can now be used to check the story drift against a code-specified maximum drift ratio.

Story drift is calculated as the relative horizontal displacement of two adjacent floors in a building. Inter-story drift can also be expressed as some factor times the story height. The allowable factor generally varies from one country code to another and may also vary depending on the type of loading. For example, in IS 1893: 2002 for seismic loading the allowable limit for inter-story drift is 0.004 times the story height whereas in IS 875 for wind loading it is 0.002 times the story height.

The drift at a particular story level in either lateral direction is calculated as the average of all the joint displacements present in that floor level. However if floor diaphragm is present, the drift is calculated at the center of mass (i.e., master joint) of the floor.

**Note:** Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command PRINT STORY STIFFNESS in the post analysis print commands section.

**Note:** For dynamic IS 1893: 2002 response spectrum, the story drift check is performed by adding a command line within the load case, rather than in the post-analysis print commands. Refer to TR.32.10.1.6 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2721) for additional information.

**Related Links**
- TR.42 Print Specifications (on page 2840)
- A. To check for inter-story drift (on page 941)

AD.2007-09.3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

**Note:** Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 4) (Build 20.07.09.22).

AD.2007-09.3.1 Steel Design per AISC 360-10

The design of steel sections per ANSI/AISC 360-10 Specification for Structural Steel Buildings (AISC 360-10) is now available in STAAD.Pro.

Refer to D1.A. American Codes - Steel Design per AISC 360 Unified Specification (on page 1366) for additional information.
To specify a design using AISC 360-10

1. Select the Design | Steel page.

   The Steel Design - Whole Structure dialog opens.

2. In the Current Code list, select the AISC 360-10.

3. Click Define Parameters list.

   The Define Parameters dialog opens.

4. Specify one or more design parameters as necessary.

5. Click Add.

   This will insert the following commands into the STAAD input file:

   ```
   CODE AISC UNIFIED 2010
   ```

AD.2007-09.3.2 Concrete Design per ACI 318-08

The design of concrete members per the ACI code in STAAD.Pro has been updated to the 2008 edition of the code.

A new parameter, LWF, has been added to account for the lightweight concrete reduction factor, λ, in equations 11-3, 11-4, and 11-5 of the code.

Refer to D1.F. American Codes - Concrete Design per ACI 318 (on page 1478) for additional information.

To specify a design using ACI 318-08 in batch mode

**Note:** Design per the 2008 edition of the ACI code is currently only available in the batch mode.

1. Select the Design | Concrete page.

   The Concrete Design - Whole Structure dialog opens.

2. In the Current Code list, select the ACI 318 2008.

3. Click Define Parameters list.

   The Define Parameters dialog opens.

4. Specify one or more design parameters as necessary.

5. Click Add.

   This will insert the following commands into the STAAD input file:

   ```
   CODE ACI
   ```

AD.2007-09.3.3 Malaysian National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Malaysian NA to EC3, use the following procedure.

The Malaysian National Annex document referred to is “MS EN 1993-1-1:2005.”

When the Malaysian National Annex to EC3 is used for design, the output section title is revised to include the Malaysian National Annex (National Annex to MS-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Malaysian NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

**Note:** For additional information, please refer to D5.D.11 Malaysian National Annex to EC3 (on page 1844) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754).
1. In the Modeling mode, select the Design | Steel tab.  
The Steel Design - Whole Structure dialog box opens.
3. Click Define Parameters…  
The Design Parameters dialog box opens.
4. Select the NA parameter in the list box.
5. Select the option for (9) Malaysia.
6. Click Add.

This will insert the following commands into the STAAD input file:

<table>
<thead>
<tr>
<th>CODE</th>
<th>EN 1993-1-1:2005</th>
</tr>
</thead>
<tbody>
<tr>
<td>NA</td>
<td>9</td>
</tr>
</tbody>
</table>

AD.2007-09.3.4 Star Angle Design per IS-800

The design of "star" angle arrangements per IS 800:2007 have been implemented in STAAD.Pro to for members subjected to axial force only. Such star angles are often used for the legs of transmission or communication towers and as bracing members in industrial buildings.

Refer to D8.E. Indian Codes - Steel Design per IS 800 - 2007 (on page 1942) for details on Limit States and Member Property Specifications in IS 800:2007 design.

Notes

- The design of star angles is only supported for IS 800:2007.
- Members must be declared as a TRUSS member (axial only). An error will be reported in the output if any other member specification is used.
- It is assumed that the star angle arrangement is a welded shape. Plated shapes are not accounted for in the program.

To specify a star angle arrangement for IS 800:2007 design

Refer to TR.20.1 Assigning Properties from Steel Tables (on page 2461) for additional information on assigning properties from steel tables.

1. Select Commands > Member Property > Steel Table > Indian.

The Section Profile Tables dialog opens to the Indian steel table.
2. Select the Angle tab.
3. Chose an angle section from the Select Angle list.
4. Select the SA (Star angle arrangement, Double Angle) Type Specification.
5. Click Add.

The section is added to the model and is available for member assignment.

AD.2007-09.3.5 IS 1893 (Part 4) 2005 Seismic Loads

Seismic loads per IS 1893 (Part 4) 2005 for industrial and stack-like structures can be generated in STAAD.Pro. These loads have been incorporated into the existing implementation of IS 1893 (Part 1) 2002 loads.

To add a seismic load per IS 1893 (Part 4) 2005

The Create New Definitions / Load Cases / Load Items dialog opens to the Seismic Parameters tab (only tab visible in this interface) and the IS 1893 - 2002/2005 code is selected.

2. Set the option for Include 1893 Part 4.
3. Do either of the following:
   - Click Generate to open the IS:1893 Seismic Parameters dialog, or
   - Type values for the command parameters directly in the current dialog table.
4. Click Add.

**Note:** Refer to TR.31.2.9 IS:1893 (Part 1) 2002 & Part 4 (2005) Codes - Lateral Seismic Load (on page 2576) for additional information.

**AD.2007-09.3.6* ABS/SRSS Combination**

A modification to the ABS (Absolute value) and SRSS (square root sum of the squares) results combinations methods.

Additional processing is now used so the resulting combination of results contain appropriate sign/direction as is required when used for design or code checking when used with the ASME NF or AISC 360 05/10 codes.

To instruct the analysis and design engine to automatically generate these load combinations for ABS or SRSS combinations, either:

- use the new, optional GENERATE parameter in the LOAD COMBINATION command, or

**Note:** Refer to TR.35 Load Combination Specification (on page 2791) for additional information.
- select the Generate Combination option in the Define Load Combinations dialog (on page 3003).

All of the permutations of positive or negative sign effects in each DOF (degree of freedom) are now considered by the analysis engine. That is, in each of the 6 DOF, both positive and negative sign are considered which results in 64 possible cases (i.e., $2^6$). As a result of this, the SRSS and ABS combinations are now presented as load envelopes (i.e., maximum and minimum values) at each member end. This is reflected in both reports and post-processing mode tables. Similarly, in the structure view in the post-processing mode, the force diagrams are now displayed graphically as an envelope rather than a single curve.

Output from the following commands displays pairs of results rows for a load at a joint (marked by an asterisk in the output):

- PRINT SUPPORT REACTION
- PRINT MEMBER FORCE
- PRINT SECTION FORCE
- PRINT PMEMB FORCE
- PRINT MEMBER STRESS

**V8i (SELECTseries 3)**

The Software Release Report for SELECTseries 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i SELECTseries 2 (release 20.07.07) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.
The Software Release Report for STAAD.Pro V8i SELECTseries 3 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i SELECTseries 2 (release 20.07.07) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

**AD.2007-08.1 Features Affecting the General Program**

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

**AD.2007-08.1.1 ISM Integration**

STAAD.Pro is now capable of transferring data to and from Bentley’s Integrated Structural Modeling technology by means of the StructLink utility.

**AD.2007-08.1.2 Export to SACS**

A new macro is included with STAAD.Pro which is used to export the current STAAD.Pro model to a SACS model, which can be opened in the SACS system Interactive Modeling program.

SACS (Structural Analysis Computer System) is a finite element structural analysis suite of programs for the offshore and civil engineering industries.

**Related Links**
- [I. To export to a SACS input file](on page 2289)

**AD.2007-08.1.3 European Cold Formed Sections per EN10219-2**

Sections defined in the publication, EN10219-2: 1997 *Cold formed welded structural hollow sections of non-alloy and fine grained structural steel. Part 2: Tolerances, dimensions and sectional properties* have been added to library of cross sections available in the program.

The following section profiles are included as separate tables in the program:

- Table 6: Circular Hollow Sections (CHS)
- Table 7: Square Hollow Sections (SHS)
- Table 8: Rectangular Hollow Sections (RHS)
To Specify a European cold formed section

1. Select the **General | Property** page.
   - The **Properties - Whole Structure** dialog box opens.
2. In the **Properties - Whole Structure** dialog box, click **Section Database**.
   - The **Section Profile Tables** dialog box opens.
3. Select the **Coldformed Steel** tab.
4. Select one of the tables available in the **European Cold Formed** section.
5. Select an entry from the **Select Profile** list.
6. Click **Add**.

   The section is now added to the Section tab in the **Properties - Whole Structure** dialog box and can be assigned to members.

AD.2007-08.1.4 Japanese JIS Hollow Sections

The catalog of available Japanese hot rolled steel sections has been expanded to include the hollow sections from JIS publications.

- JIS G3444:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* defines properties for circular hollow sections and are classed as “General pipe sections”. The existing PIPE table has been updated to ensure that it is consistent with this table.
- JIS G3475:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* defines properties for circular hollow sections and are classed as “Architectural pipe sections”. A new table for these Circular Hollow (CHS) will be added.
- JIS G3466:2005 *Design Standard for Steel Structures - Based on Allowable Stress Concept* defines properties for square and rectangular hollow sections. These will be added to the existing Japanese Sections database as two new tables: Rectangular Hollow (RHS) and Square Hollow (SHS)

Refer to [D9.C.4 Built-in Japanese Steel Section Library](on page 1989) for additional details on using the Built-in Japanese Steel Section Library.

To specify a Japanese hollow section

1. Select the **General | Property** page.
   - The **Properties - Whole Structure** dialog box opens.
2. In the **Properties - Whole Structure** dialog box, click **Section Database**.
   - The **Section Profile Tables** dialog box opens.
3. Select the **Steel** tab.
4. Select one of the tables available in the **Japanese** section: Pipe, Rectangular Hollow, Square Hollow, or Circular Hollow.
5. Select an entry from the **Select Profile** list.
6. Click **Add**.

   The section is now added to the Section tab in the **Properties - Whole Structure** dialog box and can be assigned to members.
AD.2007-08.2 Features Affecting the Pre-Processor

This section describes features that have been added that affect the pre-processor section of the program, also known as the Modeling Mode.

AD.2007-08.2.1 Wind Load Generation per ASCE 7-10

Wind loads intensity values may now be automatically generated per the 2010 edition of SEI/ASCE 7 using the ASCE-7: Wind Load dialog (on page 3039) in the user interface. This dialog allows you to generate a wind loading pattern based on the parameters used in this specification.

The primary change in wind load evaluation between the 2002 and 2010 editions of the ASCE 7 specification involve the method of calculating the force coefficient, \( C_f \), for solid freestanding walls and solid signs. The formula provided in the commentary related to Figure 6-20 in the specification is used:

\[
C_f = \frac{1.563 + 0.008542 \ln(x) - 0.06148 \cdot y + 0.009011 \cdot \ln(x)^2 - 0.2603 \cdot y^2 - 0.08393 \cdot y \ln(x)}{0.85}
\]

Where:

\[
x = \frac{B}{s} \\
y = \frac{s}{h}
\]

**To generate a wind load intensity per ASCE 7-10**

1. Add a wind load definition to the model.
2. Select this definition in the Load & Definition dialog box and click Add.
   
The Add New: Wind Definition dialog box opens.
3. On the Intensity tab, select the as Custom in the drop-down list and click Calculate as per ASCE-7.
   
The ASCE-7: Wind Load dialog box opens.
5. Specify or set the parameters needed to define the load.
   
   Click Apply prior to selecting a different dialog tab to update the dialog for the specified parameters.
6. Click OK.

AD.2007-08.2.2 Single Mass Model

A new load type, mass, is available for reference load cases. This is used to create a single mass model for all dynamic loads (i.e., seismic, response spectrum, time history, etc.). This load case can be used for seismic loads in lieu of a weight table, reducing repetitive data entry for analysis methods which would require the same data.

A new load type, mass, is available for reference load cases. This is used to create a single mass model for all dynamic loads (i.e., seismic, response spectrum, time history, etc.). This load case can be used for seismic loads in lieu of a weight table, reducing repetitive data entry for analysis methods which would require the same data.

- TR.31.6 Defining Reference Load Types (on page 2642)
- M. To add a mass model reference load (on page 876)
- M. To add mass loads to the mass model reference load (on page 877)
AD.2007-08.2.3 Eurocode Load Combination Generator

A new macro has been included with the program to generate load combinations for the Strength limit state per Eurocode – Basis of structural design, BS EN 1990:2002+A1:2005.

The load combination generator is capable of creating load combinations per equations 6.10, 6.10a, or 6.10b found in Cl. 6.4.3.2.

These equations specify the following combinations of loads:

\[ \sum_{j \geq 1} \gamma G_{k,j} + \gamma P + \gamma Q,_{1} \Psi_{0,1} Q_{k,1} + \sum_{i > 1} \gamma Q,_{1} \Psi_{0,1} Q_{k,1} \]

Alternatively, for the strength limit state, the less favorable of equations 6.10a and 6.10b may be used:

\[ \sum_{j \geq 1} \xi j \gamma G_{k,j} + \gamma P + \gamma Q,_{1} \Psi_{0,1} Q_{k,1} + \sum_{i > 1} \gamma Q,_{1} \Psi_{0,1} Q_{k,1} \]  

(6.10a)

\[ \sum_{j \geq 1} \xi j \gamma G_{k,j} + \gamma P + \gamma Q,_{1} \Psi_{0,1} Q_{k,1} + \sum_{i > 1} \gamma Q,_{1} \Psi_{0,1} Q_{k,1} \]  

(6.10b)

where

- \( G_k \) = Permanent actions
- \( P \) = Prestress actions
- \( Q_k \) = Variable actions

**Note:** The effects in each of the above equations are always additive. If any effect is negative (that is, would reduce the final sum), its effect is taken as zero.

AD.2007-08.2.4 Rigid Floor Diaphragms

A new feature has been added to easily model a rigid floor diaphragm without the need to specify a master joint at each. When specified, this command directs the engine to perform the following:

a. calculate the center of mass for each rigid diaphragm (where master joint is to be located) considering the mass model of the structure. The mass must be modeled using the new mass reference load feature (on page 140).

b. create, internally, an analytical node at the center of mass location to be included during analysis (unless a master node is specified) if an existing analytical node exists at this point, then the existing joint is used in lieu of creating a new joint.

c. search all nodes available within a diaphragm and add them as slave nodes; with the master node located at the center of mass for the diaphragm (or at the specified master node)

**Related Links**

- **TR.28.2 Floor Diaphragm** (on page 2526)
- **Node Specification dialog** (on page 2960)
- **M. To assign nodes to a floor diaphragm** (on page 811)

AD.2007-08.3 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.
AD.2007-08.3.1 API 2A WSD 21st Ed. Update

Joint checking for tubular members per the American Petroleum Institute 2A-WSD code has been updated to the 21st Edition (December 2000) of that code, including errata and supplements 1 to 3 (latest: Supplement 3 - March 2008). Additionally, the process of joint design has been simplified.

**Note:** Only simple joints and overlapping joints will be considered by the program. Other type such as grouted joints, joints with ring stiffeners etc are not be considered.

The clauses/sections in the API code that have been dealt with are:

- 4.2.1 Material strength
- 4.2.3 Minimum Capacity
- 4.2.4 Joint Classification
- 4.3 Simple joints
- 4.4 Overlapping joints

Refer to D1.J. American Codes - Steel Design per API 2A-WSD 2000 (on page 1562) for additional information on the methodology used.

**External Joint Data File**

In previous versions, the LEG design parameter was used to direct the program to generate a separate joint data file or to check a user-specified file. This file is now automatically generated or checked as needed.

As the API code allows for mixed joint types, the PUNCH column in the input file has been replaced with K, X, and Y columns which are used to designate fractional contributions of each joint class. Similarly, overlapping joints are indicated by using a negative value for the GAP between braces and the member number of the overlapping member in the OB column (replaces THETAT used in previous versions).

If the filename.PUN file is not detected in the same folder as the current STAAD input file (where "Filename" is the same as the .STD file), then the program assumes this is the initial joint design and this file is created. If, however, this file is detected, the program assumes that the that the joint design has been performed at least once and will use this file to perform the joint checks.

**To check tubular member joints per API**

The checking of joints is an iterative process done by means of an automatically generated text file.

1. Model a structure as you normally would.

   **Note:** Only circular pipe members are considered.

   **Tip:** Using TRUSS specifications helps to reduce analysis time.

2. In the **Steel Design - Whole Structure** dialog box, select **API** as the design code.
3. (Optional) Specify the factor of safety used for joint checks using the new FSJ design parameter.
4. (Optional) Specify all other necessary design parameters.
   The LEG parameter is no longer used to generate or check joint data files.
5. Specify CODE CHECK or SELECT MEMBER commands as needed and perform the analysis.
   If this the filename.PUN file is not detected in the same folder as the input file, the program assumes this is
   the first time the structure is being analyzed and generates this input file with default data for the detected
   joints. Each joint is assumed to be a Y joint by default.
6. Modify the default joint data in the filename.PUN as needed to describe the actual joint conditions.
   A text editor can be used to make changes to this file. Be sure to save changes once complete.
7. Re-analyze the STAAD input file.
   Joint check results follow the steel design output.
8. Repeat steps 3 through 7 as needed to make changes in the structure.

AD.2007-08.3.2 Shear Buckling per EC3

The design code checks performed per Eurocode 3 have been updated to include checks for shear buckling in I
Sections and PFC Sections. Eurocode 3 – Part 1 (EN 1993-1-1:2005) states in Cl.6.2.6 that the checks for Shear
buckling are to be based on the procedure in EN 1993-1-5. STAAD.Pro performs checks based on the methods
Section 5 of EN 1993-1-5:2006.

In the case of an unstiffened web, the program will check the unstiffened web capacity. If the demand due to
applied loads is greater than this capacity, the program will calculate a suitable spacing for transverse stiffener
plates in order to meet the demand.

In the case of a web with transverse stiffeners, the program will check the capacity of the web considering the
provided stiffener spacing. The program will consider both the buckling capacity of the web as well as the flange.
If the demand due to applied loads is greater than this capacity, the program will calculate a reduced stiffener
spacing for transverse stiffener plates in order to meet the demand.

**Note:** Only transverse stiffeners are taken into account. The effect of any longitudinal stiffeners is ignored.

The distance between transverse stiffeners is specified by the STIFF parameter, in the current units of length. If
no value is specified, the program assumes a spacing equal to either the member length or depth of beam,
whichever is greater.

The output file provides recommendations on the evaluation of stiffeners (e.g., adding stiffeners at a spacing or
increasing the web thickness).

Refer to D5.C.5.3 Members Subject to Shear (on page 1760) for additional information.

AD.2007-08.3.3 IS800:2007 Working Stress Method

The IS:800-2007 Steel code was deviated in concept from its -1984 version (based on Working Stress Method)
and introduced the Limit State Method of Design. The entire 2007 version of the code is devoted to the Limit
State Method of Design, except Chapter 11. This Chapter comprises of a couple of pages and has the guideline for
the Design of Steel sections as per working stress method (WSM). The approach of this new working stress
method is different from its earlier version and utilizes the concept of Section Slenderness and Section
Classification.

The program now includes design per the Working Stress Method (WSM) methodology in addition to Limit State
method for design of steel structures per IS800:2007.
Some minor corrections to the Limit State Design option have also been made.

**To specify a design using IS 800:2007 Working Stress Method**

1. In the Modeling mode, select the Design | Steel tab.

   The Steel Design - Whole Structure dialog box opens.

2. In the Current Code drop-down menu, select IS800 2007 WSD.

3. Click Define Parameters...

   The Design Parameters dialog box opens.

4. Click Add.

   This will insert the following commands into the STAAD input file:

   ```
   CODE IS800 WSD
   ```

**AD.2007-08.3.4 Surface Element Selfweight**

A new surface load has been added to include the self weight of surface elements. This command can be used to calculate and include the weight of surface elements in the analysis of a structure.

**Related Links**

- TR.32.9.2 Surface Selfweight Load (on page 2686)
- M. To add a surface selfweight load (on page 832)

**AD.2007-08.3.5 Eurocode 3 National Annexes**

Two additional country's National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: Singapore and Belgium. As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.
AD.2007-08.3.5.1 Belgian National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Belgian NA to EC3, use the following procedure.

The Belgian National Annex document referred to is “NBN EN 1993-1-1:2005.”

When the Belgian National Annex to EC3 is used for design, the output section title is revised to include the Belgian National Annex (National Annex to NBN-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Belgian NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

Note: For additional information, please refer to D5.D.10 Belgian National Annex to EC3 (on page 1838) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754).

1. In the Modeling mode, select the Design | Steel tab.
   The Steel Design - Whole Structure dialog box opens.
3. Click Define Parameters…
   The Design Parameters dialog box opens.
4. Select the NA parameter in the list box.
5. Select the option for (8) Belgium.
6. Click Add.

This will insert the following commands into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 8
```

AD.2007-08.3.5.2 Singaporean National Annex to Eurocode 3 (EN 1993-1-1:2005)

To specify a design using the Belgium NA to EC3, use the following procedure.

The Singaporean National Annex document referred to is “SS EN 1993-1-1:2005.”

When the Singaporean National Annex to EC3 is used for design, the output section title is revised to include the Singaporean National Annex (National Annex to SS-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Singaporean NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

Note: For additional information, please refer to D5.D.9 Singaporean National Annex to EC3 (on page 1831) and D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754).

1. In the Modeling mode, select the Design | Steel tab.
   The Steel Design - Whole Structure dialog box opens.
3. Click Define Parameters…
   The Design Parameters dialog box opens.
4. Select the NA parameter in the list box.
5. Select the option for (7) Singapore.
6. Click Add.
This will insert the following commands into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 7
```

**AD.2007-08.3.6 EC3 Slender Circular Hollow Sections**

Slender circular hollow (pipe) sections may now be designed per Eurocode 3 (EN 1993-1-6:2007).

Eurocode 3 – Part 1 (EN 1993-1-1:2005) –hereafter EC3-6– states in Cl. 6.2.2.5 (5) that the design of slender circular hollow sections is to be based on the procedure in EN 1993-1-6. EC3 6 deals with the design of shell structures. EC3-6 does not, however, specify additional or modified safety factors. Therefore, the default safety factors from EN 1993-1-1 are used.

**Note:** You can change these values through the GM0, GM1, and GM2 design parameters.

The program checks the plastic and buckling limit states for primary stresses based on the stress design method described in EC3-6.

Refer to [D5.C.5.6 Design of Slender pipe sections to EN 1993-1-6](on page 1771) for details on the methodology and calculations used in this design.

**AD.2007-08.3.7 User Defined Section for EC3**

The feature to design user-provided table (UPT) general sections has now been introduced steel members designed per Eurocode 3 (EN 1993-1-1:2005). However, rather than assuming that the section will behave like an I section, you are given the option of choosing the 'section-type' he would like to design the member for.

This is achieved through the introduction of a new design parameter, GST, that has the following values:

1. I-Section (Default)
2. Single Channel
3. Rectangular Hollow Section
4. Circular Hollow Section
5. Angle Section
6. Tee Section

Unless specified using the GST parameter, a general section will be assumed to be an I-Section.

**Note:** This parameter will be ignored if assigned to any section other than a General Section.

The design procedure will then account for the section type and proceed with the design as necessary. The output report will also indicate the section type considered for the design of the UPT section. The design output will indicate the section as follows:

```
*     1 ST IPE100 (UPT: DESIGNED AS I-SECTION)
   FAIL EC-6.3.2 LTB 8.591 1
   0.00 0.00 -31.25 2.50

<table>

```
What's New?

AD.2007-08.4 Features Affecting Post Processing

The following new feature has been added and existing features have been modified in the Post Processing modes. These are explained in the following pages.

AD.2007-08.4.1 Eurocode 2:2004 Slab Design

The RC Designer module (Concrete Design mode) can now be used to design slabs per Eurocode 2 (EC2 EN 1992-1-1:2004).

- **Slab design per Eurocode 2:2004** (on page 1049) - Design of EC2 slabs is performed in essentially the same way any other slab, though you should ensure that any country-specific national annex values are properly specified.

AD.2007.08.4.2 Changes to STAAD.foundation license

The license for STAAD.foundation V8i (release 5.3) is now included with STAAD.Pro contains the capability for design the following rigid foundation types:

- Isolated
- Combined
- Pile Cap

STAAD.foundation functions as a design module similar to others included with STAAD.Pro.

Contact Bentley Systems for a full license to use all of the design capabilities for STAAD.foundation or to upgrade to STAAD Foundation Advanced V8i, which includes an improved user interface, foundation toolkit wizards, plant foundation types, and FEM analysis for mat foundations.

AD.2007-08.5 Nuclear Related Features

The following new features have been added for the NRC release.

**Note:** This feature requires STAAD.Pro V8i (SELECTseries 3) NRC (build 20.07.08.22) or higher.

AD.2007-08.5.1 Design per ASME NF 3000-2001

The design per ASME NF 3000-2001 is now available as a new design code option.

Design of members per ASME NF 3000 - 2001 requires the **STAAD Nuclear Design Codes SELECT Code Pack**.

Refer to [D1.L.4. ASME NF 3000 - 2001 & 2004 Codes](on page 1616) for additional information.

AD.2007-08.5.2 ASME NF 3000-2001 Service Level Conditions

All editions of the ASME NF 3000 code now can be designed for different service level conditions as defined by that code.
Service Level Conditions are basically the loading conditions for which the plant structure and its components are to be designed. The same primary load can be multiplied by different factors to signify the different service levels. Also the load combinations for various service levels are different and pre-defined by the code.

Each ASME NF 3000 code edition now contains the a new design parameter, SLR, which is used to specify the service condition level as defined in the codes. For the case of service level D (failure), three additional new parameters –KS, KV, and KBK– are used to directly specify the service level factors.

Design of members per ASME NF 3000 - 2001 requires the STAAD Nuclear Design Codes SELECT Code Pack. Refer to D1.L.5. ASME NF 3000 Service Level Conditions (on page 1625) for additional information.

AD.2007-08.5.3 TATA Structura Sections

The catalog of available TATA Structura (Indian) hot rolled steel sections has been expanded to include the hollow sections from TATA publications.

Specifying a TATA Structura hollow section

1. Select the General | Property page.
   The Properties - Whole Structure dialog box opens.
2. In the Properties - Whole Structure dialog box, click Section Database.
   The Section Profile Tables dialog box opens.
3. Select the Steel tab.
4. Select one of the tables available in the TATA Structura section: Rectangular Hollow, Square Hollow, or Circular Hollow.
5. Select an entry from the Select Profile list.
6. Click Add.

The section is now added to the Section tab in the Properties - Whole Structure dialog box and can be assigned to members.

V8i (SELECTseries 2)

The Software Release Report for STAAD.Pro V8i (SELECTseries 2) contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (SELECTseries 1) (release 20.07.06) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-07.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.
AD.2007-07.1.1 Academic Licensing

In order to ensure that the next generation of engineer that emerges from the higher education system is up to speed using our applications, Bentley has a policy of providing software to Universities and Colleges at a favorable rate.

Students can now use STAAD.Pro under an Academic License, which is obtained through a SELECT account. Contact your regional engineer or visit Bentley.com to obtain a license.

**Note:** When using an Academic License, the program window title bar and About window indicate this. Similarly, all output (Analysis files and Reports generated from STAAD.Pro) are marked as "Academic License User."

**Caution:** The Advanced Analysis Engine is not available when using the program under an Academic Licence.

AD.2007-07.1.2 StructLink and PipeLink Plug-ins

Two plug-ins are available to you when installing STAAD.Pro: StructLink and PipeLink.

- StructLink is a utility used for the bi-direction exchange of data between STAAD.Pro and ProSteel V8i.
- PipeLink is an all new utility used for the exchange of pipe stress model data between STAAD.Pro and AutoPIPE V8i. Refer to **AD.2007-07.3.4 AutoPIPE V8i (SELECTseries 2) and PipeLink support** (on page 169) for additional the bi-directional data exchange capabilities made available through this utility.

**Note:** During the installation of STAAD.Pro, select the option to install additional programs and utilities in order to have these two utilities installed.

Refer to the documentation included with these plug-ins for additional information on their use.

AD.2007-07.1.3 Structural Dashboard Integration

Bentley's Structural Dashboard is now integrated into STAAD.Pro V8i.

Bentley's Structural Dashboard V8i is a free utility application which allows you to manage workflows and project files as well as keep up to date with latest products, news, and Be Communities happenings. This program can now be accessed from within STAAD.Pro and will launch whenever STAAD.Pro is started to assist you in managing your entire project workflow.

When STAAD.Pro is first launched after installing Structural Dashboard, a welcome dialog opens to allow you to set the automatic launch option. To launch the program and continue allowing it to launch whenever a Bentley Structural program starts, leave the option selected and click the **OK** button. Otherwise, you can de-select this option before proceeding.
Welcome to Structural Dashboard

Starting the Structural Dashboard...

- Launch Structural Dashboard on program startup

Note: To turn off launching the Dashboard, disable under 'Edit Settings' in the Dashboard or the program configuration settings.

- Show me this dialog on startup

OK

Launch Structural Dashboard on program startup

Set this option to open the Structural Dashboard application whenever STAAD.Pro is opened.

Tip: This setting can be changed at any time from within the Structural Dashboard program.

Show me this dialog on startup

Set this option to display this dialog whenever STAAD.Pro is opened.

Tip: This setting can be changed at any time from the Configure Program dialog File Options tab.

To launch Structural Dashboard from STAAD.Pro

1. Select File > Structural Dashboard...

   The Bentley Structural Dashboard V8i program opens.
Note: If Structural Dashboard has not been installed, this menu item is inactive. You can download the program from http://www.bentley.com/en-US/Promo/ISM/downloads/.

Note: Refer to Section 2.3.1 of the User Interface Manual for additional help in using the Structural Dashboard with STAAD.Pro.

AD.2007-07.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

Note: Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 2) (Build 20.07.07.31).

AD.2007-07.2.1 Time History Spectrum Enhancements

New options have been added to the spectrum input for a Time History definition which allow you to output time history input data, a Response Spectrum for a Time History load, or to use frequency-spectrum pairs. These options can be added by modifying the input command file.
Two new output options are available for reporting time history input and synthetic time history ground acceleration data used by the program for a time history load with the spectrum generation option. You can control the amount of output generated (as this can be quite large) as well.

A new option has also been added to allow you to instruct the program to use frequency-spectra pairs in lieu of period-spectra pairs for the time history spectrum input.

Related Links

- TR.31.4 Definition of Time History Load (on page 2630)
- M. To generate output for time history spectrum (on page 858)
- M. To use frequency-spectra pairs in a time history load (on page 859)

AD.2007-07.2.2 Response Spectrum Signed Results and IMR Load Cases

Two methods to produce signed response spectrum results have been added to the STAAD.Pro analysis engine. The Dominant and Sign commands may be used in the input file to produce signed output. Additionally, STAAD.Pro now includes an option to automatically generate new load cases based on a specified number of modes from the response spectrum.

Signed Results

STAAD.Pro can now assign a mathematical sign (positive or negative) to the modal results by one of two means. The first method allows you to select a DOMINANT mode, the sign of which will then be applied to all other modes. The second method will produce signed values for all results. The sum of squares of positive values from the modes are compared to sum of squares of negative values from the modes. If the negative values are larger, the result is given a negative sign.

Individual Modal Response Case Generation

The Individual Modal Response (IMR) load cases are simply the mode shape scaled to the magnitude that the mode has in this spectrum analysis case before it is combined with other modes. If the IMR parameter is entered, then STAAD will create load cases for the first specified number of modes for this response spectrum case (i.e., if five is specified then five load cases are generated, one for each of the first five modes). Each case will be created in a form like any other primary load case.

The results from an IMR case can be viewed graphically or through the print facilities. Each mode can therefore be assessed as to its significance to the results in various portions of the structure. Perhaps one or two modes could be used to design one area/floor and others elsewhere. You can use subsequent load cases with Repeat Load combinations of these scaled modes and the static live and dead loads to form results that are all with internally consistent signs (unlike the usual response spectrum solutions). You can also use the Repeat Load capability to combine the modal applied loads vector with the static loadings and solve statically with P-Delta or tension only.

The modal accelerations are multiplied by the nodal masses to produce equivalent static lateral forces for each modal load case.

Note: When the IMR option is entered for a Spectrum case, then a Perform Analysis & Change must be entered after each such Spectrum case.
What's New?

[Image of the Response Spectrum window]
To add Signed results to a Response Spectrum

1. Select Commands > Loading > Load Commands.
   
or
   Select the General | Load & Definition page and then click the New... button.
   
The Create New Load Items dialog opens.
2. Select the Response Spectra tab.
3. Select the Code you wish to use.

   **Note:** See below for using IMR generation options. All other parameters are same as previous versions.
4. Select the option to use the **Dominant Mode No.** to assign the same sign as the selected mode to all modes.
5. (Optional) Select to provide **Signed** results to

   **Note:** Selecting this option will not use the Dominant Mode No., but rather will create signed values for all results by comparing the sum of the squares values for positive and negative values to determine the governing sign.
6. Click the Add button to add this response spectrum load.

To add Individual Modal Response results to a Response Spectrum

1. Select Commands > Loading > Load Commands.
   
or
   Select the General | Load & Definition page and then click the New... button.
   
The Create New Load Items dialog opens.
2. Select the Response Spectra tab.
3. Select the Code you wish to use.

   **Note:** See above for options to add signed results. All other parameters are same as previous versions.

   **Note:** The Individual Modal Response case generation is not available for SNIIP II code response spectra.
4. Select the option to **Generate load cases for** ... to individual modal response load cases.
5. (Optional) Specify the number of modes for which load cases will be generated.

   **Note:** Selecting this option will not use the Dominant Mode No., but rather will create signed values for all results by comparing the sum of the squares values for positive and negative values to determine the governing sign.
6. (Optional) Specify a beginning load case number for the first primary load case generated from the IMR.
7. Click the Add button to add this response spectrum load.

Related Links

- TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2688)

- M. To add a generic response spectrum (on page 843)
AD.2007-07.2.3 Design of Class 4 (Slender) Steel Sections per S16-01

An update to the Canadian Steel Design code has been added for the design of Class 4 (slender) steel sections per CAN/CSA-S16-01. Previous versions of STAAD.Pro were capable of designing Section Classes 1, 2, or 3.

The design of slender Class 4 steel sections does not require any different actions or input. The analysis engine will determine if a section meets the criteria for a Class 4 section and then perform the necessary checks, if design checks have been requested for that member.

Methodology

Refer to D4.B.6 Member Resistances (on page 1705) for a detailed description of the methodology used in STAAD.Pro for performing the design of Class 4 sections per S16-01. A verification problem using this feature has also been added to Section 3B.10.

AD.2007-07.2.4 Von Mises Stresses per AIJ 2002 and 2005

Design per AIJ (Japanese) steel design codes has been updated to include checking members in accordance with Von Mises stress criteria in AIJ 2005. This check is a requirement for the design of steel structures in nuclear power plants in Japan.

The von Mises stress equation is calculated when the new MISES parameter has been set to a value of 1 (the default value of 0 does not check this condition). The calculated forces and moments are combined per the von Mises stress criteria.

To specify a von Mises stress check in an AIJ 2002 or AIJ 2005 design

1. Create a model with steel members.
3. Click the Define Parameters... button.
   - The Design Parameters dialog opens.
4. Select the MISES tab in the parameters list.
5. Select option 1 to instruct STAAD.Pro to perform the von Mises stress check as part of the steel design.
6. Click the Add button to add this parameter.
7. Close the Design Parameters dialog.
8. Assign the MISES parameter to members as needed, just as you would any other design parameter.

How the von Mises check results are included in the output depends on the level of detail (TRACK parameter) selected:

<table>
<thead>
<tr>
<th>Track 0 or 1</th>
<th>The von Mises stress is reported if this ratio is the critical condition.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Track 2</td>
<td>The value for ( f_m = \sqrt{\sigma_x^2 + 3\tau_{xy}^2} ) (numerator in the von Mises stress ratio equation) is displayed in the Stresses output category. When the von Mises check ratio is the critical condition, the value of the ratio is reported.</td>
</tr>
<tr>
<td>Track 4</td>
<td>Used for deflection checks only. Von Mises checks are not reported.</td>
</tr>
</tbody>
</table>
Methodology

AD.2007-07.2.5 Norsok N-004

The design of tubular steel (European round pipe sections) members per NORSOK N-004 Rev 2, October 2004 has been included in STAAD.Pro. The program will perform the member design for ultimate limit states (and optional deflection checks for serviceability). The tubular joints can also be automatically generated and checked per the code.

The NORSOK code has been added to the steel design code list available in STAAD.Pro. Selecting this code allows you to assign parameters, including defining the water level above the origin (for calculating hydrostatic pressure) or the

Note: N-004 refers to the superseded version of Eurocode 3 (DD ENV 1993-1-1) in several places. In such cases, the corresponding clause from the latest version of EC-3 (EN 1993-1-1:2005) has been used in the STAAD.Pro implementation.

To perform a member design per the NORSOK N-004 code

1. Create a model with steel tubular members.
   
   Caution: The Norsok code only supports pipe sections. Errors will be presented in sections other than pipe members are used.

3. Click the Define Parameters button.
4. The Design Parameters dialog opens.
5. Specify parameters as required.
   
   Note: The height of water level above the origin is specified using the HYD parameter. Alternatively, the PSD parameter may be used to define the water pressure.

7. Assign the torsion-related parameters to members as needed, just as you would any other design parameter.

To perform a joint check per the NORSOK N-004 code

1. Add the CHECK JOINT command to a new PARAMETER manually in the STAAD.Pro input file using the Editor.
2. Perform a preliminary design by selecting Analyze > Run Analysis....
   
   The program creates an external text file titled filename_JOINTS.NGo which contains the automatically generated chord and brace definitions associated with the nodes included in the CHECK JOINT command. All joints are classified as Y by default.
3. Open the text file using a text editor program (i.e., Notepad or STAAD Editor).
4. Manually edit the joint classifications as needed.
5. (Optional) Edit the Brace and Chord definitions as needed.
**Note:** The Brace and Chord members at each joint are assumed based on the relative cross section dimensions. Lengths of Chord and Brace members are taken as the analytical beam member length.

6. Save the text file and the re-analyze the structure

**Methodology**

Refer to D1.2B. Norwegian Codes - Steel Design per NORSOK N-004 (on page 2095) for a detailed description of the methodology used in STAAD.Pro for performing steel tube member design per NORSOK N-004.

**AD.2007-07.2.6 EC3 Torsion Design**

Design per EC3 [EN 1993-1-1:2005] has been enhanced to include the design of members subject to torsion. You may select to have the program execute basic or detailed torsion stress checks. Torsion design checks can be performed on I-sections, H-Sections, Channel sections, and structural hollow sections (RHS, SHS, CHS).

**Note:** The default behavior is to neglect torsion. The new TORSION parameter must be set to either 1 (basic) or 2 (detailed) to perform torsion design.

**To include torsion design for EC3 steel design members**

1. Create a model with steel members.
2. Select **EN 1993-1-1:2005** for the **Current Code** on the **Design | Steel** page.
3. Click the **Define Parameters...** button.
   - The Design Parameters dialog opens.
4. Select the **TOR(sion)** tab in the parameters list.
5. Select either option 1 (von Mises check excluding warping effects) or option 2 (detailed checks including warping effects) to include design for torsion and click the **Add** button to add this parameter.
6. Specify the loading and support conditions of members subject to torsion using the **CMT** tab in the parameters list and click the **Add** button to add this parameter.
7. (Optional) For the cases of a concentrated torque (CMT = 2, 3, or 6) somewhere along the member length (other than the default of mid-span), specify the location of the torque using the **ALH** tab in the parameters list and click the **Add** button to add this parameter.
8. (Optional) Specify the effective length of members for torsion using the **EFT** tab in the parameters list and click the **Add** button to add this parameter.
10. Assign the torsion-related parameters to members as needed, just as you would any other design parameter.

Torsion design in EC3 is given in Cl. 6.2.7 of EN 1993-1-1:2005. Therefore, this clause is used primarily for this implementation.

EN 1993-1-1:2005 does not deal with members subject to the combined effects of torsion and lateral torsional buckling. However, EN 1993-1-6 considers such a condition in Appendix A. Therefore, STAAD.Pro uses Appendix A of EN 1993-1-6 to check for members subject to combined torsion and LTB.

The following clauses from EC3 are then considered:

- Cl 6.2.7(1)
- Cl 6.2.7(9)
- Cl 6.2.7(5)
- EC-3 -6 App A
When torsion design is included (TOR = 1 or 2), then the EC3 design output includes the following sections:

- **Basic (TORSION = 1)** - The ratio calculated for stress interaction per EC-6.2.7(5) is displayed for each load case, along with the calculated values of axial force, shear in Y and Z, Bending about Y and Z, and torsion.
- **Detailed (TORSION = 2)** - The additional clauses viz. 6.2.7(1), 6.2.7(9) and EC3-6 A-1 will be included in the output. The stress interaction ratio per each is displayed for each load case, along with the calculated force and moment values used. Additional torsion calculation details are provided as well.

**Note:** If Torsion design is selected for a member which does not have any torsional moment, a warning is displayed in the output.

**Methodology**

Refer to [D5.C.5.4 Members Subject to Torsion](on page 1762) for a detailed description of the methodology used in STAAD.Pro for performing torsion stress checks per EC3.

**AD.2007-07.2.7 Eurocode 3 National Annex**

Two additional country’s National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: Finland and Poland. As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.

To Initiate a EC3-Finnish NA Steel Design, use the following procedure.

1. In the Modeling mode, click the **Design > Steel** tab.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click the **Define Parameters...** button. The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(5) Finland**.
6. Click the **Add** button.

This will insert the following commands into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 5
```

**Note:** For additional information, please refer to **D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005]** (on page 1754) and **D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005]** (on page 1792)

When the Finnish National Annex to EC3 is used for design, the output section title is revised to include the Finnish National Annex (National Annex to SFS-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Finnish NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

AD.2007-07.2.7.2 Polish National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-Polish NA Steel Design, use the following procedure.

The Polish National Annex document referred to is “National Annex to Standard PN-EN 1993-1-1”.

1. In the Modeling mode, click the **Design > Steel** tab.
2. In the **Current Code** drop-down menu, select **EN 1993-1-1:2005**.
3. Click the **Define Parameters...** button. The **Design Parameters** dialog opens.
4. Select the **NA** parameter in the list box.
5. Select the option for **(6) Poland**.
6. Select the new **PLG** parameter in the list box.

```
Note: This parameter is used to select if additional checks per clause 6.3.3 will be performed for designs using the Polish National Annex.
```

7. Click the **Add** button.

This will insert the following commands into the STAAD input file:

```
CODE EN 1993-1-1:2005
NA 6
```

**Note:** For additional information, please refer to **D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005]** (on page 1754) and **D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005]** (on page 1792)
When the Polish National Annex to EC3 is used for design, the output section title is revised to include the Polish National Annex (National Annex to PN-EN 1993-1-1). Additionally, the partial safety factors used are included in the output and are as specified in the Polish NA. The value for C1 and k factors used in the calculation of the elastic critical moment are also included in the report.

**AD.2007-07.2.8 AS4100 Physical Member Design**

The workflow for design steel members per AS 4100:1998 has been updated to incorporate the use of physical members. Physical members are groups composed of a series of analytical beam elements of the same section and which are colinear (analytical beams are the beams used in modeling in STAAD.Pro). Using physical beams allows you to design for the actual conditions of the structure and assign specifications based on the true conditions of a steel member.

Some of the physical member design updates apply to design codes other than AS 4100, such as checks in the STAAD.Pro analysis engine for physical member overlapping and colinearity. These checks were previously made in the graphical interface but now they will checked again in the engine in the event you have manually generated the STAAD.Pro input file.

The physical member mode is initiated through the Toggle Physical Member mode tool found in the Steel Design toolbar (which docked on the left hand side of the screen by default). This “mode” is used when modeling the structure and any parameter or specification added while this tool is toggled on will then only be available for physical member groups.

**Tip:** Command entries in the tree, material properties, and specifications will be designated with “(Physical)” when added in this mode.

Physical members are then formed or selected using the tools in the Steel Design toolbar. Refer to [M. Physical Members](on page 649) for additional information.

**Physical Member Restraints**

A new parameter has been added for AS 4100 physical members to describe the bracing conditions/locations on a physical member. This parameter describes where the restraint is located along the length of the physical member and the type of restraint on the top or bottom flange.
Engine Physical Member Validation

When creating physical members, the STAAD.Pro graphical interface will check to ensure that the analytical members included in a physical member definition are both interconnected and colinear. However, it is not uncommon for input files to be generated outside of the STAAD.Pro graphical environment. Thus, these checks are now performed by the STAAD.Pro Analysis & Design engine again when an analysis is performed. You will be alerted if either condition is not met.

**Tip:** The analytical members contained in a physical member definition must be colinear (or, all lying in a straight line). Each adjacent analytical member must be within 5° of one another to meet this condition.

Refer to D2.B.8 Design Parameters (on page 1641) for additional information using the new SGR (steel grade) and LHT (load height position) design parameters for steel design per AS4100. Refer to D2.B.12 Physical Member Design (on page 1649) for additional information on using the PBRACE parameter and performing the design of physical members per AS4100.

**AD.2007-07.2.9 SNiP 2.23-81 Steel Design**

Several minor enhancements have been made to STAAD.Pro regarding steel design per the SNiP 2.23-81 code.
The following corrections and enhancements were made to the SNiP 2.23-81 steel design code implementation in STAAD.Pro:

- PHI and NIU factors messages extensions explaining different design results cases
- Additional bending check for non axial compression/tension with small eccentricity
- Compressed steel member design by weakened section
- Full Check by combinations envelope for different sections of each steel member. Print of Analysis results for each member section
- Additional parameters for Steel grade by EC3 in EN 10025-2 steel tables
- Correction of other minor bugs and errors

AD.2007-07.2.10 Geometric Nonlinear Analysis Cycle Control

You are now able to limit the analysis cycle using a displacement limit control. These controls can be found on the Analysis/Print Commands dialog Nonlinear Analysis tab or input manually in the input command file.

The displacement limit control allows you to select a nodal displacement degree of freedom be monitored during a geometric nonlinear analysis. A target displacement is set and, if the number of load steps set is two or greater, the analysis will proceed step-by-step until the target displacement is met or exceeded. This provides you with an additional, practical means of limiting the number of steps used in a geometric nonlinear (GNL) analysis.

Related Links
- TR.37.8 Geometric Nonlinear Analysis (on page 2830)

- A. To specify a nonlinear analysis (on page 930)

AD.2007-07.2.11 Jindal Steel Section Database

To add a section from the available JPSL catalog, use the following procedure.

A number of Jindal Power & Steel Limited (JPSL) catalog sections have been added to the section database.

1. Select the General | Property page.
2. In the Properties - Whole Structure dialog, click Section Database. The Section Profile Tables dialog opens.
3. On the Steel tab, select the Jindal entry in the table families list.
4. Select the table, section, and type specification.
5. Click Add.

AD.2007-07.2.12* Design per ASME NF 3000 2004 Code

The design of steel sections according to the requirements in the American Society of Mechanical Engineers (ASME) specifications, Rules for the Construction of Nuclear Power Plant Components, Section III – Subsection NF has been implemented per the 2004 edition of this code and the Design | Steel page has been updated to allow the design parameters to be defined and assigned.

To perform a steel design per ASME NF 3000 2004

Use the following procedure to specify post analysis steel design code checking requirements for the ASME NF code.

1. Create a model with steel members.
2. Select **ASME NF3000 2004** for the **Current Code** on the **Design | Steel** page.

3. Click **Define Parameters**...

The **Design Parameters** dialog opens.

4. Specify parameters as required.

5. Close the **Design Parameters** dialog.

6. Assign parameters to members as needed.

7. Select Analysis > Run Analyze (or press CTRL+F5).

For more information on the technical requirements of this design code, including the full set of parameters and default values, refer to **D1.L.4. ASME NF 3000 - 2001 & 2004 Codes** (on page 1616).

**Note:** The STAAD Nuclear Code pack is required to perform designs per an ASME NF 3000 code.

---

**AD.2007-07.2.13* Update to ANSI AISC N690 1984 & 1994 Codes**

Four new Stress Limit Coefficients (SLC) parameters have been added for designs per ANSI/AISC N690 1984/1994 codes.

These parameters, SFC, SFT, SMZ, and SMY, all default to 1.0 and are used to control the interaction equations in Section Q1.6 of the ANSI/AISC N690 1984/1994 codes.

Equations Q1.6-1a, Q1.6-1b, Q1.6-2 and Q1.6-3 of code ANSI/AISC N690 1994 will be rewritten as follows:

- Members subjected to both axial compression and bending stresses are proportioned to satisfy equation Q1.6-1a:

  \[
  \frac{f_a}{F_a} + C_{my} \frac{f_{by}}{F_{by}} + \left[C_{mx} \frac{f_{bz}}{F_{bz}} + \left[(1 - \frac{f_a}{F'_e}) \frac{F_{by}}{F_{bz}}\right]\right] \leq 1.0
  \]

  and Q1.6-1b

  \[
  \frac{f_a}{(0.6 \cdot F_y)} + \frac{f_{by}}{F_{by}} + \frac{f_{bz}}{F_{bz}} \leq 1.0
  \]

  when, \( f_a / F_a > 0.15 \), as per section Q1.6.1 of the code.

- Otherwise, equation Q1.6-2 must be satisfied:

  \[
  \frac{f_a}{F_a} + \frac{f_{by}}{F_{by}} + \frac{f_{bz}}{F_{bz}} \leq 1.0
  \]

- Members subjected to both axial tension and bending stress are proportioned to satisfy equation Q 1.6-1b:

  \[
  \frac{f_a}{(0.6 \cdot F_y)} + \frac{f_{by}}{F_{by}} + \frac{f_{bz}}{F_{bz}} \leq 1.0
  \]

Refer to **D1.K.2.1 Design Process** (on page 1582) for additional information on using the ANSI N690 1984 and 1994 codes.

---

**AD.2007-07.2.14* Load Combination Enhancements**

It is now possible to refer to a previously defined load combination within a new load combination. For example, a SRSS combination of individual response spectrum cases can now be referenced in a load combination along with dead load, live load, etc.

There are no changes to the input file syntax. Load combination definitions may now refer to existing load combination numbers along with load case numbers.

**Note:** There is no limit to the amount of load combination “nesting” which can be done in STAAD.Pro, other than the total limit of load cases and load combinations allowed by the program.

---

**Related Links**
**What's New?**

**STAAD.Pro V8i**

- **TR.35 Load Combination Specification** (on page 2791)
- **Define Load Combinations dialog** (on page 3003)
- **M. To define a new load combination** (on page 866)

**AD.2007-07.2.15* Enhancement to Maximum Number of Response Spectrum Load Cases**

STAAD.Pro now supports up to 50 response spectrum load cases, instead of the previous limit of four. Refer to **TR.32.10.1 Response Spectrum Analysis** (on page 2687) for additional information on using Response Spectra.

**AD.2007-07.3 Features Affecting Post Processing**

Several new features have been added and existing features have been modified in the Post Processing modes. These are explained in the following pages.

**AD.2007-07.3.1 RAM Connection V8i (SELECTseries 1) Support**

The enhancements included in Bentley’s RAM Connection V8i (releases 6 and 7) are now available in STAAD.Pro. This includes new connection types, new codes, and design for seismic loads.

Some of the new features and enhancements include:

- Now compatible with versions of RAM Connection V8i up through release 7.0 (SELECTseries 3).
- British Design Code - Connection design per BS5950-1:2000 (British standard) has been added. This code can now be selected along side AISC codes.
- AISC Seismic Provisions - The seismic provisions of AISC 341-05 have now been added for connections per AISC codes.
- Seismic Frame Management - A new Seismic Frames page has been added to assign the lateral seismic resisting system classification to frames for connection design. This page is also used to add plastic hinge locations to beam members.
- Base Plate Design is now available for AISC (ASD & LRFD) connections. Column base plates are available in the Smart Connections dialog and Column-Brace gusset base plates are available in the Gusset Connections dialog.
- The RAM Material dialog has been expanded to accommodate for various materials from different countries. UK steel, bolt, and weld types have been added, as well as concrete and anchor bolt materials for US base plate design.

**Note:** A notification message may be displayed when selecting the RAM Connection mode that you need to provide some additional material properties.

- Several new selection methods have been added to the **Select > By Joints** > sub-menu.
- Reports have been enhanced with code references and display of formulas used.

**AD.2007-07.3.2 RC Designer**

Several new features have been added and existing features have been modified in the RC Designer mode. These are explained in the following pages.

- **ACI 318M-05 (Metric)** (on page 1218) - Uses “soft” conversions for US standard bar sizes. Therefore, bar sizes are unchanged from US Customary units, but named for the nearest metric equivalent. The conversion for material properties is performed similarly.
**Note:** Mixed units cannot be used for designs per ACI 318-05. The metric version is listed as separate design code when creating design briefs.

- **GB50010** (on page 1318) - Concrete beam and column design per GB50010 is now available.
- **IS456** (on page 1325) has been updated to the 2000 edition and now includes an option to perform additional reinforcement detailing checks for seismic conditions per **IS 13920:1993** (on page 1061). This code is used for the ductile detailing of reinforced concrete structures subjected to seismic forces.
- Documentation has been expanded for the **SP52-101-03 design briefs** (on page 1342) and **technical reference** (on page 1066).

**AD.2007-07.3.2.1 ACI 318 Metric**

A new design code has been added for beams, columns, and slab element designs in the RC Design module for the metric version of ACI 318-05.

ACI 318M-05 is the standard published by the American Concrete Institute which describes the equations to be used for metric design. It differs from the normal ACI 318-05 standard in that it has been converted to a “soft metric” form, where conversions have been applied to the numbers used in the formulae and to the bar sizes, and then some rounding has been done. This means that the bars to be used are the same as with US customary units, but they are quoted to the nearest millimeter.

**Note:** Refer to **D. American Concrete design per ACI 318M - 2005** (on page 1105) for additional information.

**Note:** A valid license for the U.S. Design Codes (Standard) package is required to use this feature.

To create a ACI 318M-05 Design Brief for columns or beams

1. Open a model in RC Designer.
2. Select the Groups/Briefs Page in the page control.
3. Click the **New Brief** button at the bottom of the Design Briefs table.
   - The New Design Brief dialog opens.
4. Enter a title in the **B#** field.
5. Select **ACI 318M-05** in the **Design Code** list.
6. Select the appropriate **Design Type** (either Beam or Column).
7. Click the **OK** button.
   - The corresponding ACI 318M-05 Beam Brief or ACI 318M-05 Column Brief dialog opens, depending on the choice made above.
8. Specify parameters as needed.

   **Note:** The design briefs are identical to those for ACI 318-05 checks with all entries being input in “soft” metric units as indicated.

9. Click the **OK** button.

**AD.2007-07.3.2.2 GB50010**

Concrete beam and column design per the GB 50010-2002 code is now available.

The GB50010 checks are initiated by selecting this code for the design brief and selecting the appropriate parameters. Refer to **D. Using GB50010 (Chinese) Concrete Member Design** (on page 1318) and **D. Chinese Concrete design per GB50010** (on page 1025) for additional information on using this new feature.
**Note:** A valid license for the Asian Design Codes package is required to use this feature.

To create a GB50010 Design Brief for columns or beams

1. Open a model in RC Designer.
2. Select the Groups/Briefs Page in the page control.
3. Click the **New Brief** button at the bottom of the Design Briefs table.
   - The New Design Brief dialog opens.
4. Enter a title in the **B#** field.
5. Select **GB50010** in the **Design Code** list.
6. Select the appropriate **Design Type** (either Beam or Column).
7. Click the **OK** button.
   - The corresponding GB50010 Beam Brief or GB50010 Column Brief dialog opens, depending on the choice made above.
8. Specify parameters as needed.
9. Click the **OK** button.

---

**AD.2007-07.3.2.3 IS456 with Seismic Design per IS13920**

Design of columns and beams per IS 456 is now performed per the 2000 edition of that code. The option to perform additional reinforcement detailing checks for seismic conditions per IS 13920:1993 is also now available. This code is used for the ductile detailing of reinforced concrete structures subjected to seismic forces. The IS456 checks are initiated by selecting this code for the design brief and selecting the appropriate parameters. Additional seismic checks per IS 13920 are specified by selecting this option on the design brief General tab. Refer to D. IS 13920 Seismic Design (on page 1061) and D. IS456 (on page 1325) for additional information on using this new feature.

**Note:** A valid license for the Indian Design Codes package is required to use this feature.

To create an IS456 Design Brief for columns or beams

1. Opens a model in RC Designer.
2. Select the Groups/Briefs Page in the page control.
3. Click the **New Brief** button at the bottom of the Design Briefs table.
   - The **New Design Brief** dialog opens.
4. Enter a title in the **B#** field.
5. Select **IS456** in the **Design Code** list.
6. Select the appropriate **Design Type** (either Beam or Column).
7. Click the **OK** button.
   - The corresponding IS456 Beam Brief or IS456 Column Brief dialog opens, depending on the choice made above.
8. Specify parameters as needed.
9. Select the option to **Check for IS 13920** on the General tab to perform additional seismic design.
   - **Note:** See the following procedure for designing for IS 13920.
10. Click the **OK** button.
    - Design longitudinal and shear reinforcement in beams per IS13920
1. In the **IS456 Beam Design Brief** dialog General tab, select the **Check for IS13920** option.

2. Perform a beam design.

3. Select the **Earthquake** page.

4. Select the appropriate load case is selected to perform the seismic checks to allow for a strong column-weak beam mechanism.

   The program internally calculates the moment capacities of the beams and columns framing into a joint and assign a "pass/fail" status depending on the corresponding beam and column capacities at that joint for the direction under consideration.

5. Select the **Earthquake | Reinforcement** page to review the status of the IS 13920 design.

**AD.2007-07.3.3 Enhanced Geometric Nonlinear Post Processing**

The graphical display of the results of a geometric nonlinear analysis have been improved. The Graphs are now easier to read and a new control has been added to limit the maximum Load Step displayed.

When a structure is analyzed with a geometric nonlinear analysis, the nodal displacements can be viewed by selecting the Node | Nonlinearity page in the Post-Processing mode. The Node Displacements Curve has been enhanced and a new control has been added to the Node Displacements table to limit the maximum Load Step plotted.

In the event that a load level is specified which exceeds the non-linear buckling capacity of a structure, the analysis performed by STAAD.Pro will produce exceedingly large post-buckling displacements. This signifies that the load steps in this post-buckling level are beyond the scope of designed performance of the STAAD engine (and likely beyond the load level and effects intended by the engineer). In these cases, the scale of the non-linear load displacement curve was did not adequately display the pre-buckling characteristics due to the very large scale required to display the post-buckling displacements.

Now, in the event of a large post-buckling load, the maximum load level scale of the Load Level vs. Displacement graph can be limited to the currently selected load step by selecting this option on the Node Displacements table, thus allowing you to see the pre-buckling behavior.
AD.2007-07.3.4 AutoPIPE V8i (SELECTseries 2) and PipeLink support

STAAD.Pro is now capable of two-way data exchange with AutoPIPE via a new PipeLink utility. Additionally, the tools for transferring loads between the pipe model and the structural model have been enhanced such that you can now select, update, and remove loads to be applied to the structural model.

**Note:** For details on the updates to Bentley AutoPIPE V8i, refer to the documentation included with that product.

Some of the new features and enhancements include:

- The integration between STAAD.Pro and AutoPIPE has been enhanced to allow bi-directional transfer of data between STAAD.Pro and AutoPIPE. This is accomplished through a new plug-in program called PipeLink, which is used to generate common database files for use in both AutoPIPE and STAAD.Pro. [Exporting data](on page 3110) back to AutoPIPE is now possible.
- The system now allows pipe models to be imported from a number of databases and these models may all be stored locally. The active model can be selected from the [Pipe Model dialog](on page 3111).
- The loading transfer process has been significantly revised. The mappings between the pipe loadings and the generated structure loadings (on page 3119) are recorded so that these structure loadings may be revised or removed rather than the previous once-only method. Further, loads can now be modified individually.
- Connections can now be individually selected to transfer moment to the supporting STAAD model structure by selecting the [Lever Arm](on page 3117) option at each connected Pipe Node.
- The program now connects pipe supports – rather than pipe nodes – to the structure. This allows both node and support labels to be used. This allows additional filters in the [connection wizard](on page 3113) and also allows STAAD.Pro to import multiple supports at a single support node.
Pipe supports are now graphically displayed with icons which reflect the nature of the pipe support. The display of these icons, along with other pipe model elements, can be controlled through a new tab in the Diagnose dialog (on page 3121).

**AD.2007-07.3.5 Transverse IRC Loading in STAAD.Beava**

For the specific bridge width, IRC (Indian Road Congress) chapter 6-2000, table 2, clause 207.4 defines the rules to combine the live loads. This new feature allows you to either use these IRC live load rules or use an iterative, custom method. If the IRC rule option is selected, this function uses the appropriate live loads and number of design lanes and the generates all the possible load combinations as stated for this particular bridge width. Otherwise, you can select a specific live load and design lane to generate combinations.

Loading rules per IRC Chapter 6 are applied in much the same way as previous codes. The defined roadway for the selected deck(s) is divided into design lanes and the selected load class is applied to the structure achieve the specified actions.

*To specify loading per IRC Chapter 6*

1. Open an analyzed bridge model in the Bridge Deck mode.
2. Create Deck and Roadway definitions.
3. Generate influence surfaces for the structure.
4. Select **Loading > Run Load Generator**.

   The Load Generation Parameters dialog General tab opens.

5. Select IRC Chapter 3 for the Design Code and select the appropriate Limit State.

   The <code> tab updates to display IRC Loading.

6. Select the **IRC Loading** tab.

   ![Image of IRC Loading tab]

7. Select the appropriate **Loading Class**.

   **Note:** Combinations of the AA, B, and 70R vehicles have been added to the included vehicle definitions. These may be reviewed in the Vehicle Database dialog.

8. (Optional) Specify an impact factor or modify the **Multiple Presence Factors** as needed.
9. Specify the decks for consideration on the Decks tab and the load effects to dictate load placement on the Node Displacements, Support Reactions, Plate Center Stresses, and Beam End Forces tabs.

10. Click the OK button.

The program places the selected loads in design lanes to produce the maximum or minimum effects requested. A text file containing a summary of the generated loads and corresponding effects is opened in a text editor for review.

Related Links
- IRC Specific Parameters (on page 3135)

AD.2007-07.3.6 STAAD.foundation V8i Integration

The export of support geometry and reactions to STAAD.foundation V8i can now be initiated from within STAAD.Pro using the Foundation Design mode. This feature is similar to the Import STAAD.Pro File capability included in STAAD.foundation.

When selected, the Foundation Mode opens the Foundation page which contains a view of the whole structure and the Foundation Design Options dialog.

From here, you can select to include all supports, you can graphically select supports, or you can specify a list of support numbers for exporting to a STAAD.foundation project. Similarly, the load cases from the analysis are listed for inclusion in the STAAD.foundation project.

Tip: Models containing a large number of supported nodes or load cases may result in slow performance on older computer hardware. Exporting a limited set of data can be used to improve performance in STAAD.foundation in these cases.

Planned future enhancements also include the export of mat foundations modeled in STAAD.Pro for design in STAAD.foundation.

AD.2007-07.3.7 Additional Section Databases in RAM Connection mode

Steel section databases for the following countries are now available for use when design connection in RAM Connection mode:

- Indian
- European
- Japanese
- Australian

Note: Connection design is only performed per the US and British codes available in RAM Connection.

AD.2007-07.4 Additional Features

The following features have yet to undergo testing and are presented "as is."

Note: Items labeled with an asterisk (*) were added in the QA&R release of V8i (SELECTseries 2) (Build 20.07.07.32).

Beta Features

The following features have yet to undergo testing and are presented "as is."
AD.2007-07.4.1* Design of Class 4 “Slender” Sections in IS800:2007

The design of slender classified sections (only rolled or welded I sections) per IS:800-2007 has been added to STAAD.Pro.

The IS:800-2007 code does not provide any clear guidelines about what method should be adopted for the design of slender section. The “Flange Only” concept has been adopted where it is assumed that flexure is taken by the flanges alone and the web will resist shear with adequate shear buckling resistance. This means that the flange elements must be non-slender with slender web element to qualify for slender section that can be designed. If any of the flanges become slender, the design will not be performed for Bending and a warning message is displayed.

Refer to D8.E. Indian Codes - Steel Design per IS 800 - 2007 (on page 1942) for additional information on the design procedures used for slender sections for IS800:2007 as well as a verification example problem.

V8i (SELECTseries 1)

The Software Release Report for STAAD.Pro contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (release 20.07.05) This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-06.1 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-06.1.1 CIS/2 Translator Update

The STAAD.Pro tool to import and export models with the CIS/2 translator has been enhanced for the transfer of models into 3D modeling, such as Intergraph SmartPlant® 3D (SP3D).

The CIS/2 (CimSteel Integration Standard, Version 2) allows for the transfer of steel models using a prescribed data standard in the STEP (Part 21) format. These files can contain different models including analysis models. In previous versions of STAAD.Pro, CIS/2 files could not be imported into an existing STAAD file. The import process has now been updated so that new STAAD input files can be created or existing input files updated from a CIS/2 file.

STAAD.Pro will retain all relevant information generated by SP3D – including the object IDs (GUIDs) – when importing CIS/2 files. Further modeling operation will be done in STAAD.Pro which includes special purpose load generations, analysis, design and member selections and modifications. You may then export out to a CIS/2...
STEP file and retain all information inherited from SP3D STEP file and addition/deletion/modification information performed in STAAD.Pro.

Using import and export of STEP files in SP3D, further modification can be made in SP3D and the STAAD.Pro model can be updated its model. Only geometry, member properties, boundary condition information are within the update scope of STAAD.Pro. While updating the STAAD.Pro model, no other information will be considered. This round-trip process can be repeated an unlimited number of times.

Additionally, two new VBS Macros have been included in the User Tools to aide in the verification of model integrity before and after update operations using the Import dialog. These may be found in the User Tools drop-down menu in the File toolbar or under Tools > User Tools.

**New User Tools (VBS Macros)**

Two VBS macro are developed to assist users to confirm the model integrity before and after the update operations.

- **List Object GUIDs**
  
  Opens the GUID Report tables. This is useful to verify that the GUIDs are same as those in SP3D.

- **CIS/2 Object Update Report Tool**
  
  Used to capture model state before an update operation (Create Pre-Update Report) and then same tool can be invoked again after the update process to generate a report showing what exactly has been updated (Create Post-Update Report).

AD.2007-06.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-06.2.1 ANSI/AISC N690-1984 Design Code

For steel design, STAAD.Pro compares the actual stresses with the allowable stresses as defined by the ANSI/AISC N690-1984: Nuclear Facilities - Steel Safety-Related Structures for Design, Fabrication, and Erection.

The parameter CODE AISC N690 1984 is used to initiate code checking per ANSI/AISC N690-1984.

The full details for this code - including parameters, commands, and technical background - are in D1.K.2. ANSI/AISC N690-1984 Code (on page 1582).

To use the ANSI/AISC N690 1984 code

1. In the modeling mode, select the Design | Steel page.
2. Select AISC N690 1984 in the Current Code drop-down list.

AD.2007-06.2.2 Update to Russian Concrete Design

The Russian SNiP concrete design routines have been updated to accommodate new reinforcement and concrete class definitions. In order that these new classes can be assigned to members that are to be designed, the following changes have taken place in the RCL, BCL, and RHS parameters.

Refer to D13.A. Russian Codes - Concrete Design Per SNiP 2.03.01-84* (on page 2113) for additional information.

Additionally a few other minor updates have been incorporated to ensure axial tension is ignored in column design and that the provided area of steel in both directions is not less than the minimum.

Note: STAAD.Pro supports design of concrete beams and columns to Russian SP52 code is supported in the interactive RC Designer module (Concrete Design Mode in the GUI). For more details of the RC Designer see D. Interactive Concrete Design (on page 1005). For details on the SP52 details see "AD.2007-1001.4.1 Beam and Column Designs to the Russian Concrete Code SP52."

To select reinforcement or concrete class definitions

1. In the modeling mode, select the Design | Concrete page.
2. Select **SNiP 2.03 01-84** in the **Current Code** drop-down list.
3. Click the **Define Parameters** button below the model outline panel.
4. The **RCL**, **BCL**, and **RSH** parameters have the new definitions available. Refer to [D13.A.2 Design Parameters](on page 2114) for additional information.

   Reinforcement Class for longitudinal reinforcement (RCL):
Compression class of concrete B (BCL):

Reinforcement class for shear reinforcement (RSH):
AD.2007-06.2.3 Eurocode 3 National Annex

Two country's National Annex to Eurocode 3 have been incorporated into the Steel design module in STAAD.Pro: United Kingdom and France. As with the other National Annexes to EC-3, this implementation will make use of the NA parameter.
Caution: The GB1 parameter (which, in fact was common to the base EC-3 and was a reminiscent of the previous DD ENV implementation of EC-3) has been removed. Hence any legacy STAAD files that have the GB1 Parameter defined will need to be revised to take out this parameter as it is no longer valid as per the latest EN1993.

AD.2007-06.2.3.1 United Kingdom National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-UK NA Steel Design, use the following procedure.

The UK National Annex document referred to is "NA to BS EN 1993-1-1:2005".

1. In the Modeling mode, click the Design | Steel page.
3. Click the Define Parameters button.
   The Design Parameters dialog opens.
4. Select the NA parameter in the list box.
5. Select the option for (1) United Kingdom.
6. Click Add.

This will insert the following command into the STAAD input file:

CODE EN 1993-1-1:2005
NA 1

Note: For additional information, please refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754) and D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1792)

AD.2007-06.2.3.2 French National Annex to Eurocode 3 (EN 1993-1-1:2005)

To Initiate a EC3-French NA Steel Design, use the following procedure.

The French National Annex document referred to is "Annexe Nationale a la NF EN 1993-1-1:2005".

1. In the Modeling mode, click the Design | Steel page.
3. Click the Define Parameters button.
   The Design Parameters dialog opens.
4. Select the NA parameter in the list box.
5. Select the option for (4) France.
6. Click Add.

This will insert the following command into the STAAD input file:

CODE EN 1993-1-1:2005
NA 4

Note: For additional information, please refer to D5.C. European Codes - Steel Design to Eurocode 3 [EN 1993-1-1:2005] (on page 1754) and D5.D. European Codes - National Annexes to Eurocode 3 [EN 1993-1-1:2005] (on page 1792)
AD.2007-06.2.4 Chinese Static Seismic Loading

A simplified base shear method of the seismic load generation for the Chinese GB50011-2001 code has been added to STAAD.Pro V8i.

This set of commands may be used to define and generate static equivalent seismic loads as per Chinese specifications GB50011-2001. This load uses a static equivalent approach, similar to that found in the UBC. Depending on this definition, equivalent lateral loads will be generated in the horizontal direction(s).

Related Links
- TR.31.2.5 Chinese Static Seismic per GB50011-2001 (on page 2563)
- Add New Seismic Definitions dialog (on page 3044)
- M. To add a seismic load definition (on page 840)

AD.2007-06.3 Features Affecting the RAM Connection Design Mode

Several new features have been added and existing features have been modified in the RAM Connection Design Mode. These are explained in the following pages.

Note: Full use of the RAM Connection Mode requires access to a valid RAM Connection license. If you do not possess a license, contact your Bentley account manager to have it added to your SELECT licenses. Without a valid license, only a small subset of the full range of available RAM connections can be utilized.

AD.2007-06.3.1 RAM Connection V8i Support

The enhancements included in Bentley’s RAM Connection V8i (release 5.5) are now available in STAAD.Pro. Additionally, the connection assignment and design process has been streamlined within STAAD.Pro. Now, joints and connections can be automatically assigned for a set of selected members and connection designs can be grouped together. Additionally, when a connection is edited using the RAM Connection pad, those changes will be saved in the STAAD.Pro model design.

Connections are designed in the newly updated RAM Connection Mode by creating “Joints,” from the geometry, section properties and forces resulting from the analysis and assigning a design brief made up of connection templates. A suitable connection design, if one is available, will be reported once you have selected the appropriate connection templates.

In previous releases of STAAD.Pro, you were able to only select and assign a connection to individual joints. Now, any number of joints may be selected and designed. Further, connection design is performed automatically for you once appropriate templates have been selected for the selected joints. These enhancements greatly reduce the time required for connection design in models of all sizes.

Tip: The selected load envelope is now used for all connection designs, instead of per design brief as in previous versions of STAAD.Pro.
AD.2007-06.4 Features Affecting the Piping Mode

STAAD.Pro can utilize the pipe layout and reactions created in the applications ADLPipe or AutoPipe. The pipe model can be imported in the Piping Mode. The following describes the method of using the Piping Mode and features recently added to this mode.

AD.2007-06.4.1 AutoPIPE Integration Enhancements

An enhancement to how pipe/structure connections are assigned has been made to the Piping module. A new Support Connection Wizard is available to allow you to add multiple supports to the entire model or a subset of a model, based on some general parameters.

Note: Pipe-structure links are not part of the undo system. Nodes created at the end of the wizard will be removed by an undo but the links are not changed.

Within the Piping mode, after the pipe model has been loaded, you will be able to call up a modeless connection wizard. The wizard will take you through the following steps:

1. Defining the set of pipe nodes to consider.
2. Defining the set of structural beams to consider.
3. Defining the set of structural nodes to consider.
4. Setting range and tolerance parameters.
5. Previewing and accepting the determined connections.

Potential connections will be determined after step 4 and fully created at the end of step 5.

Potential connections will be determined by finding the closest beams and closest nodes to each pipe node. In the previewing stage the closest five items, along with a “to ground” option, will be available as options to you, sorted by distance.

Parameter Page / Connection Finder

The connection finding routine runs in two parts. First looking at beams (length of perpendicular from beam) and then looking at nodes (straight line length). The five closest found connectable points are saved to be presented on the results page. In order to provide control over the connection finder, several parameters are available to you for editing. The default values of distance-based parameters will depend on the base unit of STAAD.Pro.

General

- Max. Range: double: default 2m / 6’ : Potential connections beyond Max. Range will be discarded.
- Insert nodes into beams at connection points: default true : This parameter effects the connection of the structures rather the point finding algorithm. If set true a new node will be created at each intermediate beam point and the connection made to that rather than to the beam itself. If the algorithm finds new node points within “End Tolerance” of each other then only one new node will be added.

Beam

- End Tolerance : double: default 5cm /2” : To allow for differences in precision and to avoid very short beam breaks this parameter will determine at what distance from the node the perpendicular will be considered to be at the node itself.
Allow Non-Perpendicular Connection at End Nodes: Boolean : default true: This is only really relevant if the node subset does not explicitly include the nodes at the end of members in the beam subset. If set "true" the beam end nodes will be included in the node search. If set 'false' the end nodes of a given beam will only be considered for connections perpendicular to the beam, unless they have been explicitly added to the node subset.

This page has no effect on structure diagrams. The connection finding routine is run when advancing from this page.

V8i (release 20.07.05)

The latest What's New document for STAAD.Pro V8i contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro V8i (2007 build 04). This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-05.1 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-05.1.1 Geometric Nonlinear Analysis

The range of analysis options has been supplemented with a new solution to account for nonlinear effects of moderate displacement and small strain. This solution holds for where the element distortion is small and small rotations are assumed.

Note: The nonlinear analysis command is available with the Advanced Analysis license.

AD.2007-05.1.2 IS 800:2007 Steel Design

The Indian Bureau of Standards has released a new version of the design code for the design of steel structures, known as IS 800:2007. This replaces the previous version of the code (also supported in STAAD.Pro), IS 800:1984, which was versified again in 1998. This is a new approach to steel design and is based on the limit state design rather than a stress based design of the old code.
The Steel Design section has been enhanced to include design per IS 800:2007. Both section checking and selection routines are supported.

The design will follow the same process as used by all other steel design codes currently available in STAAD.Pro. The design of each member is controlled through a set of parameters that have been added to the GUI Steel Design Dialog under the title **IS 800:2007**.

The design engine will allow all standard section database sections and User Table sections to be designed.

The design process followed:

1. Check slenderness  
2. Check classification  
3. Check tension forces  
4. Check compression forces  
5. Check bending forces  
6. Check interaction

The results will be:

1. output to the ANL file  
2. available in the member query  
3. available in the post processing mode in the Design Results table

**Note:** *Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if SET Z UP is used).*

**AD.2007-05.1.3 Eurocode 3 Includes National Annex**

A number of countries that have signed up to the replace their current steel design standards with the Eurocode, EN 1993-1-1:2005, known commonly as Eurocode 3, have published their National Annex documents. These documents make small changes to the base document and STAAD.Pro has been updated to incorporate some of these National Annex documents. Currently, the Dutch and Norwegian National Annexes have been added to the STAAD.Pro engine.

A new parameter, NA, that sets the default material gamma factors and any additional changes outlined in the country specific National Annex such as specific equations or methods.

The output file printout has been updated to indicate which National Annex (if any) has been used in a code check / select process. (For all TRACK settings)

**To specify checks per a National Annex**

In order to include additional check specified by a National Annex, do the following:

1. From the Modeling mode Design | Steel page, select **EN 1993-1-1:2005** from the current code list.
2. Click Define Parameters to launch the Design Parameters dialog.
3. Select the parameter NA from the list.
4. Select the radio button for the National Annex you wish to use; or leave as Basic in order to use EC3 without additional checks.

5. Click **Add** to add the NA parameter to the code check.

6. Click **Close** to dismiss the dialog once parameter definitions are complete.

A design performed to the new Eurocode 3 National Annex is displayed in the output file (*.ANL) with the following header, in addition to the base EC3 output:
### What's New?

**STAAD.Pro V8i**

Torsion and deflections have not been considered in the design.

---

**Note:** The previous, development edition of Eurocode 3 is included as the Code EN3 DD.

---

**AD.2007-05.1.4 Eurocode 8**

Eurocode 8: Part 1 [EN 1998-1-1:2004] contains specific requirements and recommendations for building structures that are to be constructed in seismic regions. Essentially, these fundamental requirements have been provided to ensure that the structures can sustain the seismic loads without collapse and also – where required – avoid suffering unacceptable damage and can continue to function after an exposure to a seismic event.

As with all Eurocodes, a National Annex Document should accompany the use of Eurocode 8 in each of the European nations.

---

**AD.2007-05.1.5 AIJ Concrete Design Update**

An old version of Japanese concrete code based on the AIJ standard for structural calculation of Reinforced Concrete Structures (1985 edition) was previously implemented in STAAD.Pro batch mode design. Recently, critical errors in the column design and beam design were discovered and corrected. In addition, the AIJ concrete design has been updated to incorporate the latest AIJ standard for structural calculation of Reinforced Concrete Structures (1991 edition).
Generally, this implementation will be invisible to you. The 1985 edition of the AIJ has been completely replaced by the 1991 edition for the design of concrete members per the AIJ. The existing commands as described in D9.A. Japanese Codes - Concrete Design per 1991 AIJ (on page 1969) are applicable to the 1991 edition.

**AD.2007-05.2 Features Affecting the Concrete Design Mode**

An existing feature has been modified in the RC Designer section of the program, also known as the Concrete Design mode. This is explained in the following pages.

**AD.2007-05.2.1 RC Designer Member and Envelope Import**

The ability to create physical members in STAAD.Pro has been introduced since the original implementation of the RC Designer. Previously these members did not get carried through into the RC Designer, thus requiring the extra step of re-creating these members, and possible confusion if the same member numbers were not used.

Similarly, load case/combination envelopes were not carried through into the RC Designer, requiring extra care in identifying which load cases were being considered when examining the output.

The physical member definitions are now passed through to the RC Designer along with the other structural data from STAAD.Pro. Envelope definitions are also carried through and examined to see if they contain any dynamic loading for which it may be inappropriate to use the analysis results directly.

Generally, this implementation is invisible to the user. Physical member assignments made in the STAAD.Pro Modeling mode will be carried over to the RC Designer (Concrete Design mode). If existing designs are re-examined, the user may be warned if member numbers or constitution (in terms of beam elements included) differ between the STAAD.Pro Modeling mode and the RC Designer definitions, and the option is given to delete the RC Designer members with their results. For envelopes, the user is prompted if the envelope numbers or constitution differ between RC Designer and STAAD.Pro Modeling mode.

Additionally, a warning may be presented to the user if any envelope incorporates a dynamic load case. This is because the dynamic load cases in STAAD.Pro only produce positive values for moments and forces, even though it is understood that the loading actually reverses. Concrete design based on an envelope of positive forces only would be seriously under-reinforced.

**V8i (release 20.07.04)**

The Software Release Report for STAAD.Pro V8i contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2007 build 03. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

**AD.2007-04.0 New Features Affecting the General Program**

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.
AD.2007-04.0.1 ProjectWise Integration

ProjectWise is an engineering project team collaboration system which is used to help teams improve quality, reduce rework, and meet project deadlines. One of the major pieces of functionality provided by ProjectWise is an Integration Server which allows data to be managed and shared across a distributed enterprise.

STAAD.Pro has been enhanced so that the model STD data file can be managed on a ProjectWise server. Installation and management of a ProjectWise server is beyond the scope of this document and should be obtained from the ProjectWise installation.

A local ProjectWise client should be installed which allows access to ProjectWise repositories.

When STAAD.Pro is launched, the option to open and check out a STAAD.Pro STD file from a ProjectWise repository is made available from the Project Tasks on the Start Page thus:

This is also available from the File menu while still on the Start Page prior to opening a model:
If a suitable ProjectWise client is not installed, then the link on the Start Page is shown as unavailable with a red line through the icon thus:

![Project Tasks]

As authentication is required to access files stored on a ProjectWise repository, a login dialog allows the required details to be entered either with specific user credentials or by using the current windows login credentials thus:

![ProjectWise Log in]

Files that are accessed from a ProjectWise server are “Checked Out” and stored locally during the STAAD.Pro session until the file is closed and then it is returned to the server.

The first time that a successful link to a ProjectWise server is established, a location in which check out files are to be stored locally and additionally, where all the auxiliary data files are stored whilst STAAD is running is required. Afterwards and on all future occasions, the ProjectWise open dialog presented is then presented where the repository can be navigated and filtered as defined in the ProjectWise documentation.
Note the significance of the icons next to the STAAD filenames. These indicate the status of the file such as the current document, checked out to you, or locked as checked out to some other user. Refer to the ProjectWise documentation for a full description of each icon.

With a file checked out and loaded in STAAD.Pro, it is possible to see the ProjectWise Properties, by selecting the option from the ProjectWise toolbar or File menu:

If working on a STAAD model that has not originated from a ProjectWise server (e.g., starting a new file) and it has been decided that it needs to be added to a repository, then at any time whilst working in the STAAD.Pro environment, clicking on the toolbar option Add to ProjectWise server, or equivalent File > ProjectWise menu option will launch the following dialog:
Selecting the option **No Wizard** offers the following dialog into which the file details can be entered. 

Clicking on Save, adds this model to the repository, but indicates its status as checked out until the file is closed in STAAD.Pro and the model checked back in.

Alternatively, by selecting the **Advanced Wizard** option the data needed to define the ProjectWise data file is presented in the following four steps:

1. Advanced Wizard
2. Select target Folder

3. Document Properties
4. Create the document

Creates the document and marks it as checked out until the file is closed and checked in to the server.

Four integration functionalities have been added. These are:

- Open a STAAD model from a ProjectWise repository.
- Save a local STAAD model into a ProjectWise repository.
- Update an existing model from ProjectWise.
• Review model properties (meta-data) which has been opened from a ProjectWise repository.

Note that access to all of these functionalities is available from ProjectWise sub-menu under the general File menu described below.

**Saving changes of a Checked Out model Back on the Server**

When a model is checked out from a ProjectWise server, selecting Save or Save As, only maintains a local copy of the model. There are two methods available to update a checked out model. Firstly, during a STAAD.Pro session, it is possible at any time to save any changes back on the server by selecting the Update Server Copy icon from the ProjectWise toolbar or from the File > ProjectWise menu.

First save updates to the file locally. If not, then this will be prompted. Then the following dialog is displayed which allows a comment to be added to this model, thus:

![Update Server Copy dialog](image)

The file remains checked out and can be continued to be worked on.

The second method is automatically generated when a checked out model is closed. This launches the Check In dialog that displays the file(s) that are to be checked in and provides four actions:
Check In
This copies the local version of the STAAD model back to the server and releases it so that it is available for others to modify. If the option Create New Version is selected, then a new copy of the file is created on the server which becomes the current version of the model. The status of the checked out model is changed to read only on the server and can be used as a reference to a stage in the development of the model.

Update Server Copy
This updates the model on the server with the current local model, but does not change its status which remains as checked out.

Free
This changes the status of the model as checked in which allows other users to take control and check out the model, but does not update the server model. Thus local changes will be discarded.

Cancel
This cancels any change to the status of the model or the model itself on the server.

Menu
The commands that drive the ProjectWise integration are defined in the main File menu thus:

File > ProjectWise
The Add... command is available when using a locally opened (not checked out from ProjectWise), which allows the current model to be saved into a ProjectWise repository.
The Open... command is available when a suitable ProjectWise client has been installed to allow access to a repository from which to check out a STD file.
The Update Server Copy command is available when working on a checked out file and the changes made on the model can be
Toolbar

A new toolbar named ProjectWise has been added that duplicates the commands from the File > ProjectWise menu, thus:

Notes

1. For more details on ProjectWise refer to the ProjectWise client installation documentation.
2. This functionality requires access to a version V8i or greater of ProjectWise.

AD.2007-04.0.2 CIS/2 Update

The STAAD.Pro tool to import and export models with the CIS/2 translator has been enhanced to work with international models and transferring models into 3D modeling such as SmartPlant 3D.

The CIS/2 (CimSteel Integration Standard, Version 2) allows for the transfer of steel models using a prescribed data standard in the STEP (Part 21) format. These files can contain different models including analysis models. The STAAD.Pro CIS/2 translator only operates on the analysis model within the file. While STAAD.Pro has supported a wide range of the steel sections that this standard can support, this enhancement allows a far greater range of sections to be imported/exported with this tool.

Import

The CIS/2 import can be initiated after starting a new model and before creating any model data, selecting the menu option, File > Import...

Selecting the CIS/2 option and clicking on the “Import” button allows selection of a suitable STEP file. This file is a text file and will be similar to the following extract:

```
ISO-10303-21;
HEADER;
/* Generated by software containing ST-Developer */
/* from STEP Tools, Inc. (www.steptools.com) */
FILE_DESCRIPTION(
    /* description */ ('CIS2 Export File'),
   */
```
Once a file has been selected, the data is ready to be imported with the CIS/2 import tool thus:

Clicking the Import button then runs the model import where the CIS/2 file is processed and the analysis model data is extracted to form the STAAD.Pro model.
Note that as the CIS/2 file is being processed, a log file which identifies the data that has been utilized in the STAAD model is produced and displayed which can be saved as a text file for future reference.

**Export**

The CIS/2 Export is available for any model that has been created as an option in the menu item File>Export...

Selecting the CIS/2 option and clicking on the “Export” button allows the definition of a suitable STEP filename and folder to locate it. Once again the CIS/2 tool is presented, this time with an Export Model button at the bottom which when clicked creates the STP file.
Once again, when the export has completed, the user can save the log file which is produced as the model is converted into the STEP format.

Enhancements

The STAAD.Pro CIS/2 import now recognizes sections defined from standard databases such as those defined in Japanese, British, Indian, Australian and European tables.

The import/export has been enhanced to support the ability of STAAD.Pro to create double sections, such as back to back angles and channels or double wide flange sections. Additionally, it now supports the creation of T sections which are defined in STAAD.Pro as a wide flange section that is split at mid height.
Although CIS/2 has been developed for the processing of steel models, the STAAD.Pro translator will now support the transfer of prismatic properties normally associated with concrete sections. This means that sections defined as PRISMATIC in a STAAD.Pro model will be included in exported STP file and can be imported if they exist.

AD.2007-04.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

AD.2007-04.1.1 ASME NF Steel Design Codes

The design of steel sections according to the requirements in the American Society of Mechanical Engineers (ASME) specifications, Rules for the Construction of Nuclear Power Plant Components, Section III – Subsection NF has been implemented and the steel design page has been updated to allow the design parameters to be defined and assigned.

The design requirements for the following years have been added:
- 1974
- 1977
- 1989
- 1998

Post analysis steel design code checking requirements for the required ASME NF code can be selected by entering the Design | Steel page and setting the ASME code / year in the Current Code option in the Steel Design - Whole Structure dialog:

The method for selecting design parameters and assigning them to the members to change them from the default values is exactly the same as for all other steel design codes. Additionally, choosing members that are to be checked or selected for maximum utilization follows exactly the same method as for all other steel design codes.

For more information on the technical requirements of this design code, including the full set of parameters and default values, see the new section in the D1.L. American Codes - Steel Design per ASME NF Codes (on page 1588).
Note: In order to run a design check to any of the ASME NF design codes, then access to a STAAD Nuclear Code pack will be required.

AD.2007-04.1.2 Floor Response Spectrum

A new dynamic feature has been added that allows the extraction of a response spectrum from a collection of nodes that constitute a floor when subjected to a time history loading. This information can then be used in conjunction with equipment that will be supported by these floors and is often required by the equipment manufacturers.

Users will require a license for the advanced analysis module to access this feature.

The required commands (see AD.2007-04.2.3 Floor Response Spectrum (on page 206) for more information) can be entered graphically after adding the analysis command by selecting the new analysis sheet Generate Floor Spectrum thus:

![Generate Floor Spectrum sheet](image.png)

This command should follow immediately the definition of the analysis and will require defined groups of nodes which need to be defined first.

The following displays the layout of this sheet:
Note: Each line of settings constitutes one floor which can have one or more floor groups assigned. The resulting response spectra will be based on the collective responses of all the nodes in the selected groups.

Once the required options have been set, click on the Add button to add the command set to the model which should appear in the Analysis Window thus:
Once the command has been added and the file saved, the analysis can be run which will generate a new sub-page in the Post-Processing Mode in the Dynamics Page called Floor Spectrum:
Entering this page, STAAD.Pro will display the floor spectrum thus:

To change graphs to that of another selection of node groups or damping ratio, then select the required set from the drop list in the Response Spectrum Table.

The graph is initially set to display the results on a log/log graph. This can be changed to a linear graph by right clicking on the graph and selecting the "Linear Graph" option. Additionally, the calculated points on the graph can be added by again right clicking on the graph and selecting the option ‘Show Points’.
The data that has defined the graph can also be exported to a text file and used in a third party application by right clicking on the graph and selecting the option “Save Data in Text File…”

Related Links
- TR.37.10 Floor Spectrum Command (on page 2833)
- A. To generate a floor spectrum (on page 935)
- P. To display floor spectrum results (on page 2218)

AD.2007-04.1.3 Russian Wind Loading

The wind loading as defined in the design code SNiP 2.01.07–85 “Loads and Actions” added in this version of STAAD.Pro can be added graphically to the model by modifications in the Loads Page.

There are two areas where the graphical user interface has been updated:

**Wind Load Definition dialog**

The dialog has been updated to allow the entry of the required parameters for a Russian Wind Load definition thus:-

![Wind Load Definition dialog](image)

This will create a definition which can be added to a wind load case.
Wind Load

Note: The first load case which has a Russian Wind Load command added to it will consider all other loads defined in it as the masses to be considered for calculating the dynamic effect which is required by this command.

For technical details of this wind loading see section AD.2007-04.2.2 Russian Wind Loading (on page 205).

AD.2007-04.1.4 Additional Standard Profile Databases

An additional Australian cold formed database has been provided to complement the cold formed sections databases currently provided.

The following database and tables have been added from OneSteel. Duragal®, Galtube® and Tubeline®

Australian Cold Formed Steel Hollow Sections

Circular Hollow Sections:

- Galtube Plus®, 26.9mm to 76.1 mm diameter
- Tubeline, grades C250L0 (AS1163) and 350L0 (AS1163), 26.9mm to 457.0mm
Rectangular Hollow Sections

- Duragal®, grade C450L0 (AS1163), 50x20mm to 150x50mm
- Galtube Plus®, grade C350L0, 50x20mm to 75x25mm
- Tubeline®, grade C350L0 (AS1163), 50x20mm to 250x150mm

Square Hollow Sections

- Duragal®, grade C450L0 (AS1163), 20x20mm to 100x100mm
- Galtube Plus®, grade C350L0, 20x20mm to 65x65mm
- Tubeline®, grade C350L0 (AS1163), 13x13mm to 250x250mm

AD.2007-04.2 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-04.2.1 ASME NF

The design of steel sections according to the requirements in the American Society of Mechanical Engineers (ASME) specifications, Rules for the Construction of Nuclear Power Plant Components, Section III – Subsection NF has been implemented and the steel design page has been updated to allow the design parameters to be defined and assigned.

The design requirements for the following years have been added:

- 1974
- 1977
- 1989
- 1998

For the list of parameters and commands including the default values, please refer to the D1.L. American Codes - Steel Design per ASME NF Codes (on page 1588).

For each steel member that is checked, the following checks are performed according to the clauses for that year:

1. Slenderness check
2. Tension
3. Compression
4. Bending (a) About major axis, (b) About major axis
5. Shear
6. Combined Stresses

AD.2007-04.2.2 Russian Wind Loading

The wind loading commands have been enhanced to allow the creation of wind loading as defined in the in Russia by the design code SNIP 2.01.07–85 Loads and Actions.
The basic quantity in the wind loading is the characteristic (normative in Russian terminology) wind pressure. The reference wind velocity pressure corresponds to a 10-minute time-averaged velocity pressure at 10-metres height in a flat terrain, based on a 5-year return period. This wind pressure is the static component of the wind load. The total wind pressure consists of static and fluctuating components. If the structure is sufficiently flexible, according to the code provisions, the dynamic structural response to the fluctuating wind component must be taken into account.

The updated wind loading commands automatically perform both the aerodynamic and structural load analysis of vibration-susceptible buildings and structures.

The wind loading commands have been updated to support the wind loading as defined in the Russian design code. This requires the creation of the following commands.

There are three parts to creating a Russian wind load on a STAAD Model.
1. Definition of the wind load requirements
2. Application of the wind load definition within a load case
3. Cut-off frequency or mode shape

Related Links
- TR.30.1 Cut-Off Frequency, Mode Shapes, or Time (on page 2539)
- TR.31.3 Definition of Wind Load (on page 2623)
- TR.32.12.3 Generation of Wind Loads (on page 2779)
- M. To add a SNiP wind load definition (on page 837)

AD.2007-04.2.3 Floor Response Spectrum

The following commands have been added in order to allow the response spectrum of floors to be extracted from a time history analysis.

This command is used to specify the calculation of floor and/or joint spectra from time history results. The Floor Response Spectrum command must immediately follow an analysis command. That analysis can only contain a single time history load case.

Related Links
- TR.37.10 Floor Spectrum Command (on page 2833)
- A. To generate a floor spectrum (on page 935)

AD.2007-04.3 Features Affecting the Post-Processing (Results Mode)

Several new features have been added and existing features have been modified in the post-processing section of the program, also known as the Results Mode. These are explained in the following pages.

AD.2007-04.3.1 Time History Animation

In order to visualize the displacement that occurs on a model during the application of a time history load, a new toolbar icon has been added which allows the displacement at a specific time instance to be displayed.
The results toolbar has been updated to include a new option which is activated when the displacement diagram icon has been clicked and the current load case contains time history loading:

For a time history load case the displacement that is displayed will be defined by the time instance entered in the above edit box. Alternatively the time can be set from a sliding scale by clicking on the button with the down arrow icon which displays the following option setting:

The slider scale is based on the overall time for which the time history analysis has been performed. The displacement is produced at the time at which the slider arrow is dragged to and the mouse button released.

If the **Apply Immediately** option is selected, then the application will attempt to render the displacement diagram dynamically as the slider is dragged up and down the scale of time. For large models this may prove to be too demanding on the graphics system and left un-checked which means that the displacement diagram will be produced at the time step at which the slider arrow is released.

Note that the displacement diagram will be set to the scale as defined in the Scales sheet in the **Structure Diagrams** dialog box.

Additionally note that it is possible to view the time v displacement of individual nodes by clicking on the Dynamics>Time-Disp in the post processing mode which is only available for models that include time history.
**AD.2007-04.3.2 Enhanced Plate Stress Results**

In order to provide additional understanding of stress distribution in finite element models, STAAD.Pro has expanded the sets of results that can be reported for each element both in the Plate Centre Stress Table and graphically using the Plate Stress Contour.

To view the results data of plate elements, enter the Post Processing (Results) Mode, and click on the Plate Contour Page on the left menu.

**Plate Centre Stress Table**

The new Combined Stresses sheet in the Plate Centre Stress table provides resolved stresses for the top (positive local Z) and bottom (negative local Z axis) surface for each plate element, referred to as the Top Combined Stresses and Bottom Combined Stresses respectively.

The combined stresses are calculated thus:

**Top:**

\[
\begin{align*}
S_{X_{\text{top}}} & = SX + \frac{MX}{S} \\
S_{Y_{\text{top}}} & = SY + \frac{MY}{S} \\
S_{XY_{\text{top}}} & = SXY + \frac{MXY}{S}
\end{align*}
\]

**Bottom:**

\[
\begin{align*}
S_{X_{\text{bottom}}} & = SX + \frac{MX}{S} \\
S_{Y_{\text{bottom}}} & = SY + \frac{MY}{S} \\
S_{XY_{\text{bottom}}} & = SXY - \frac{MXY}{S}
\end{align*}
\]

where

\[
\begin{align*}
S & = \frac{t^2}{6} \ t \\
tS & = \text{average plate thickness}
\end{align*}
\]

**Plate Stress Contour**

The Plate Stress Contour sheet of the Diagrams dialog has been enhanced to allow visualization of these stresses. The six new stress results are available in the Stress Type pull down menu thus:
What's New?

STAAD.Pro V8i User Manual
STAAD.Pro 2007 Release Reports

This section of the Software Release Report contains detailed information on additions and changes that have been implemented in builds of STAAD.Pro 2007 since the release of STAAD.Pro 2006 build 1005. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

STAAD.Pro 2007 Build 03 Release Report

The Software Release Report for STAAD.Pro 2007 Build 03 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 Build 05. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

STAAD.Pro 2007 Build 02 was a maintenance update and only contained a number of minor updates which are listed in the Revision History text file.

AD.2007-03.0 Features Affecting the General Program

This section describes features that have been added that affect the general behavior of the STAAD.Pro application.

AD.2007-03.0.1 RSS Feed added to the Start Page

The STAAD.Pro Start Page has been updated to include a new section which has been configured to display the most current information about STAAD and Bentley that will be of use to you, such as program updates, seminars, and training courses. This has been done by adding an RSS (Really Simple Syndication) reader on the application front screen.
Each news item is identified with a title which is a link to a website which can be clicked on and will launch your web browser and load that website and a brief summary of the item.

The item is categorized with one of the following five categories:

- **Important**
- **Bentley General**
- **Release**
- **Educational**
- **News**
Additionally, each item is marked for specific regions thus:

To configure which messages are displayed and for which region, click on the **Configuration...** link on the Start Page. Select the RSS Feed and click in the categories and regions to remove those that are not required.

**Note:** Items that have been classed as Important and for All Regions cannot be disabled, but other issues can be by un-checking the boxes next to them.
AD.2007-03.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

---

AD.2007-03.1.1 New Meshing Options

The Parametric Models section STAAD.Pro has been enhanced with additional meshing options to provide three methods for creating a finite element mesh. These methods are classified as **Basic**, **Standard**, and **Advanced**.

The original content of this topic has been superceded by content in the main help. Please refer to the Mesh Parameters dialog (on page 2912) in the User Interface help for current details.

---

AD.2007-03.1.2 Enhanced Automatic Load Combination Generation

The Automatic load combination generator has been enhanced with two options that define whether notional loads should be included in the combinations and how combinations are created to allow a far greater range of combination conditions to be considered.

The two new options are displayed on the top rows of the dialog box that is opened from the Pre-Processor menu item: **Commands > Loading > Edit Auto Rules**

---

**Related Links**

- **Edit Load Rules for Auto Load Combination Generator dialog** (on page 3035)
- **M. To define automatic load combination rules** (on page 867)
AD.2007-03.1.3 Generation of Primary Load Cases Using Repeat Load Commands

With the large number of combinations that are required by design codes, STAAD.Pro introduced a tool to allow the combinations to be created automatically based on a rule set. This functionality has been enhanced to allow the automatic creation of equivalent combinations, but using primary load cases and the REPEAT command.

The use of the COMBINATION command to obtain results for a collection of load cases that occur together is entirely valid when using first order analysis and models that are not dependant upon the forces in them (such as tension only members or one-way supports). In these cases, the law of superposition allows the results of each load case to be multiplied by a scaling factor and added together. However, for models where this does not apply, such as using a P-DELTA analysis, TENSION ONLY members or ONE-WAY supports, then the law of superposition does not necessarily apply. For this reason, STAAD.Pro has the ability to create primary load cases which replicate the effect of a combination, but in a primary load case. This means that the analysis will solve the load case by using the applied loading rather than simply adding the results. This is achieved in a primary load case by using the REPEAT command.

For full details of the REPEAT command see TR.32.11 Repeat Load Specification (on page 2770).

There are three parts to automatically creating primary load cases equivalent to combinations.

1. Define the rules that determine how load case types are to combined
2. Define the individual primary load cases classified with their type
3. Create the combinations.

By selecting the option Create Repeat Load Cases all the load case combinations in the Selected Load Combinations list will be created into primary load cases:

Note the difference in the Load & Definition dialog when comparing a generation of Combination load cases rather than Primary load cases with REPEAT commands:
What's New?

STAAD.Pro 2007 Release Reports

**Related Links**

- *Edit Load Rules for Auto Load Combination Generator dialog* (on page 3035)
- *M. To define automatic load combination rules* (on page 867)

**AD.2007-03.1.4 Design Code List**

The list of supported design codes in the design dialog boxes has been updated to represent the actual document rather than the country where this is possible.

The list of codes displayed in the Steel, Concrete, Timber, and Shearwall Design dialog boxes has been updated such as here for the Steel **Design** dialog box:
Note that there is no change to the input or output generated from the design unless noted in the section, AD. 2007-03.2 Features Affecting the Analysis and Design Engine (on page 223).

AD.2007-03.1.5 Additional Standard Profile Databases

An additional Japanese cold formed database has been provided to complement the cold formed sections databases currently provided.

The following database and tables are available.

*Japanese Cold-Formed Steel*

- Box Column Press
- Box Column Press (Tough)
- Box Column Roll
AD.2007-03.1.6 IBC 2006

The static equivalent method for performing dynamic analysis as per the IBC 2006 code has been implemented. This follows the principals and methods as in the IBC 2000 and IBC 2003 codes previously implemented.

When the **General | Load** Page is selected, the right hand side of the screen will display the following if no load cases exist in the model.

![Image](image1.png)

**Definitions** contains the options through which one creates the **Define** block of data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases and time history load cases.

When the tree view is expanded, it will display thus:

![Image](image2.png)

To define the definition of the IBC 2006 select the Seismic Definitions and click on Add. As with other seismic definitions, there are three parts to the exercise,

1. Defining the code and parameters
2. Defining the weights to be considered
3. Include the definition in a primary load case
In the dialog box that is displayed, select **IBC 2006** from the drop-down list.

In this dialog box, the required data is entered into the parameters as described below.

There is an option to **Include Accidental Load**, if this is selected the analysis will include an additional accidental torsion component as described in section 12.8.4.2 of ASCE 7-05.

Refer to the Add New Seismic Definitions dialog (on page 3044) and TR.31.2.12 IBC 2006/2009 Seismic Load Definition (on page 2592) for details.

After specifying the values for the parameters, click on the **Add** button.

Note that the **Load** dialog box has been updated with the new command.
As described earlier, the second part of the process is to identify the structural weights that should be considered. These can be added once the defined parameters have been created by clicking on the Add button. The dialog box is updated to display the various weights that can be added thus:

**Selfweight**

This is the selfweight of the structure.

**Joint Weights**

These are the concentrated weights acting at one or more joints.

**Member Weights**

Distributed and concentrated weights acting on member spans are specified through this option. After clicking the Member weight button, the Member weight dialog box appears, as shown below.
Select the Concentrated or Uniform load type from the Loading Type drop-down list. Enter the intensity of the distributed weight or magnitude of the concentrated weight as the case may be, along with the location of the load.

**Element Weights**

If the structural model consists of plate elements representing entities like floor slabs, the pressure loads on those slabs can be considered for weights calculation for lateral load generation per UBC/IBC/other codes. This is done with the help of the Element Weights option. Its parameters include the magnitude of the uniform pressure, and the elements they are applied on. Since it is a weight, it is a quantity without a sign.

**Reference Load**

Reference Load cases which are described in AD.2007-1001.1.12 of the STAAD.Pro 2007 Software Release Report can be referred to using this option. Loads which are specified under Reference Loads can be used as weights for IBC.

**Floor Weights**

In many situations, a user may decide not to include the structural slabs in his/her analytical model. Hence, the model may be solely the skeleton framing system consisting of the beams, columns and bracing members.

Under these circumstances, the loads which act on the slab can no longer be applied on the structure using the ELEMENT PRESSURE options. This is because there are no elements to represent the slab. So, an alternative is to apply the load using the FLOOR LOAD option. It is described in detail in TR.32.4 Area, One-way, and Floor Load Specifications (on page 2664).

Within a UBC/IBC/other codes definition, the FLOOR WEIGHT is the counterpart for the FLOOR LOAD just as MEMBER WEIGHT is the counterpart for a MEMBER LOAD, and an ELEMENT WEIGHT is the counterpart for an ELEMENT LOAD.

**Note:** Its parameters are hence very similar to what are found in a normal FLOOR LOAD definition. XRANGE, YRANGE and ZRANGE options allow the user to narrow in on panels at specific regions of the building. The pressure value is provided as a quantity without sign because it is contributing to the overall weight - a numerically positive term.
Once the seismic definition, including weights, has been specified, it should be included in a one or more primary load cases.

Select **Load Cases Details** and click on **Add**.

In the dialog box that is displayed, provide a **Title**, select the loading type as 'seismic' (although this is not strictly required, just useful for future reference) and click on **Add**.

More load cases can be added in this manner.

To add load items to our first load case, keep the expression **1: SEISMIC IN THE X DIRECTION** highlighted and click on the **Add** button.
Enter the **Factor**, **Direction**, etc. and click on **Add**.

The **Load** dialog box will display the new load item.
We can continue adding other load items to this load case in a similar fashion.

For more information on other UBC and IBC load definitions, see TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2544). To find more information about including the seismic loads in a primary load case, see TR.32.12 Generation of Loads (on page 2771).

**AD.2007-03.2 Features Affecting the Analysis and Design Engine**

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

**AD.2007-03.2.1 Selfweight Command with a Member List**

When considering stage construction, it is occasionally necessary to create load cases which include the effects only of the additional parts of structure. In order to do this the SELFWEIGHT command has been enhanced to allow a member list to be added which will be processed and only selfweight on that list will be considered.

This command may be used to calculate and apply the SELFWEIGHT of the structure for analysis. This allows you to enter body weight of the structural components. In other words, it allows different parts of the structure to be excited with different accelerations.

Refer to TR.32.9 Selfweight (on page 2685) for details on using member lists with the Selfweight command.
**Example**

```plaintext
LOAD 1 DEAD AND LIVE LOAD
SELF WEIGHT X 1.4 LIST 4 TO 10
SELF X 1.0 _PLATEGRP1
SELF
SELF Y -1.4
SELF X 1.4 ALL
SELF WEIGHT Z 1.4 _SOLIDGRP1
SELF Y -1.4 YR 10.5 10.51
SELF Y -1.4 X
```

In above example, the first specification includes factored weight of member (/plate/solid) 4 through 10 along global X direction and the second includes weight of all members (/plates/solids) associated with group _PLATEGRP1. The third command includes weight of all structural components towards gravity direction (SELF WEIGHT Y -1.0).

SELFWEIGHT specification for definition of static method of seismic load generator also is capable of accepting list. Only there is no direction specification for this command.

Similarly, the SELFWEIGHT specification when used in a Reference Load is also capable of handling a list.

---

**AD.2007-03.2.2 Direct Analysis**

The AISC 360-05 Appendix 7 describes a method of analysis, called Direct Analysis, which accounts for the second order effects resulting from deformation in the structure due to applied loading, imperfections and reduced bending stiffness of members due to the presence of axial load.

This is a non-linear iterative analysis as the stiffness of the members is dependent upon the forces generated by the load. The analysis will iterate, in each step changing the member characteristics until the maximum change in any Tau-b is less than the tau_tolerance, If the maximum change in any Tau-b is less than 100*tau_tolerance and the maximum change in any displacement degree of freedom is less than the disp_tolerance; then the solution has converged for this case.

There are two steps involved in setting up a Direct Analysis.

1. Specify the definition with a DEFINE DIRECT command.
2. Specify a direct analysis method with the command PERFORM DIRECT ANALYSIS

**Note:** Like all other analysis methods, by specifying the direct analysis parameters and only including a PERFORM ANALYSIS command, will result in only a first order elastic analysis, not a direct analysis to be performed.

**Related Links**

- [M. To define direct analysis parameters](on page 852)
- [A. To specify a direct analysis](on page 929)

---

**AD.2007-03.2.3 Notional Loads**

A number of design codes require that a notional load be considered. Typically this is defined as a percentage of the gravity loads. What has been added to STAAD.Pro is an enhancement on the REPEAT LOADS command so
that Primary and /or Reference load cases can be selected and a percentage of them can be applied in the appropriate global direction.

The addition of the Notional Loads command in the GUI is as an additional option on the Repeat Load option of the New Load Items, thus:

Both Principal and Reference load cases can be selected and moved into the Notional Load Definition where the required factor and direction can be specified.

The notional loads are calculated and applied as joint loads. Note that the actual values of the applied loading are not displayed in the GUI until after the analysis has been performed.
AD.2007-03.2.4 STP Parameter Added to AISC 360-05 Design

The AISC 360-05 design of wide flange depends on whether the section is formed from a rolled process or from plates welded together.

The parameter STP has been added to the list of parameters to indicate whether the section is built up from welded plates or from a rolling process. This is then used to determine the appropriate slenderness ratio as defined in table B44.1 from AISC 360-05. This parameter takes the following values:

1. Rolled Section
2. Built-up section

The default value is 1.0

Related Links
- D1.A.6 Design Parameters (on page 1378)

AD.2007-03.2.5 Updated and Additional Standard Steel Grades in Eurocode 3

The standard steel grades are referenced in the Eurocode 3 have been provided as standard steel grades in order that the appropriate buckling curves can be selected.

The steel grade can be specified using the parameter SGR which accept values of 0 to 5. This translates to the following:

<table>
<thead>
<tr>
<th>Grade</th>
<th>SGR</th>
</tr>
</thead>
<tbody>
<tr>
<td>S 235</td>
<td>0 (default)</td>
</tr>
<tr>
<td>S 275</td>
<td>1</td>
</tr>
<tr>
<td>S 355</td>
<td>2</td>
</tr>
<tr>
<td>S 450</td>
<td>3</td>
</tr>
<tr>
<td>S 460</td>
<td>4</td>
</tr>
</tbody>
</table>

Note: If a user-defined yield stress PY is specified, the buckling curve will still be determined from the SGR setting (i.e., if not specified, it will be based on the default SGR parameter). Therefore, if setting a user PY, this should be preceded in the file by the appropriate steel grade command.

AD.2007-03.2.6 Russian Response Spectrum

The Response Spectrum functionality has been enhanced with the ability to create response spectra as defined in the SNiP II-7-81.

To create a response spectrum as defined in the SNiP code, enter the General | Load & Definition Page and create or select the load case which is to be used. Click on the Add... button and select the Response Spectra option from the left panel.
Enter the required data in the provided fields and click on the Add button to include the command in the selected load case of the data file.

**Related Links**
- **TR.32.10.1.11 Response Spectrum Specification per SNiP II-7-81** (on page 2759)

**AD.2007-03.2.7 Eurocode 3 Updated to Support Design of Slender Box Sections**

Both the ENV and DD versions of Eurocode 3 steel design need to design box sections that have slender elements.
Members that are specified with steel hollow box section properties that contain slender elements can now be designed to Eurocode 3. Previously, these members would not be designed and result in a warning in the output stipulating that slender members are limited to I section properties only.

**AD.2007-03.2.8 AIJ 2005 Steel Design**

The AIJ has updated the Japanese steel design code, AIJ 2005. This design code has been implemented and complements the existing Japanese steel design code AIJ 2002. The changes are minor and the code checking process remains the same as the previous AIJ design.

The design parameters are the same and apply as defined for the current AIJ, the only exception, however, is the **Current Code** parameter which must be set to **AIJ 2005**. This setting is available from the GUI list of codes.

![Steel Design - Whole Structure](Image)

Note that a design performed to the new AIJ 2005 standard is displayed in the output file (*.ANL) with the following header:

```
STAAD.PRO CODE CHECKING - (   AIJ 2005     )
********************************************************************
```

The equivalent header for a code check (or member selection) to the older standard is displayed thus:

```
STAAD.PRO CODE CHECKING - (   AIJ 2002     )
********************************************************************
```

**AD.2007-1003.2.9 IBC 2006**

In **AD.2007-03.1.6 IBC 2006** (on page 217), the graphical screens containing the implementation of the seismic loading chapters of the IBC 2006 and ASCE 7-05 codes were described. In this section, the technical details and command syntax for the parameters of that feature are described.

**Related Links**

- **TR.31.2.12 IBC 2006/2009 Seismic Load Definition** (on page 2592)

**AD.2007-03.2.10 IBC 2006 Response Spectrum**

This command may be used to specify and apply the **RESPONSE SPECTRUM** loading as per the 2006 edition of the IBC specification "International Building Code (IBC)," for dynamic analysis. The graph of frequency–acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

**Related Links**

- **TR.32.10.1.8 Response Spectrum Specification per IBC 2006** (on page 2743)
AD.2007-03.3 Features Affecting the Concrete Design Mode

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2007-03.3.1 ACI 2005 Beam, Column, and Slab Design

The RC Designer mode has been enhanced with a new design module to support the design of beams, columns and slabs to the publication ACI 318-05: Building Code Requirements for structural Concrete and Commentary. This is in addition to the previous ACI design module which is to ACI 318-99.

To create a design brief with the ACI 318-05 design requirements and parameters, on the Groups/Briefs Page start a New Brief by clicking on the New Brief button and select the ACI 318-05 option from the Design Code drop list thus:

![New Design Brief]

**Note:** To perform designs to the ACI 318-05 design code, you will need to have access to a valid license for 'US Design Codes (Standard)'.

AD.2007-1003.3.2 AS 3600 Beam and Column Design

The RC Designer mode has been enhanced with a new design module to support the design of beams and columns to the publication AS 3600-2001: Concrete Structures. The implementation includes both Amendment 1-2002 and Amendment 2-2004.

To create a design brief with the AS 3600 design requirements and parameters, on the Groups/Briefs Page start a New Brief by clicking on the New Brief button and select the AS 3600 option from the Design Code drop list thus:
To design beams and columns with the AS 3600 design brief follow the instructions as described in the RC Designer help (on page 1241).

**Note:** To perform designs to the AS 3600 design code, you will need to have access to a valid license for ‘Canadian/Australian/SA design Codes’.

**AD.2007-1003.3 EC2 2004 Beam and Column Design**

The RC Designer mode has been enhanced with a new design module to support the design of beams and columns to the publication BS EN 1992-1-1:2004. This is the base Eurocode 2 document with the British National Annex.

To create a design brief with the Eurocode 2 design requirements and parameters, on the Groups/Briefs Page start a New Brief by clicking on the New Brief button and select the EC2:2004 option from the Design Code drop list thus:

To design beams and columns with the EC2:2004 design brief follow the instructions as described in the RC Designer help (on page 1286).

**Note:** To perform designs to the EC2:2004 design code, you will need to have access to a valid license for ‘Eurocodes’.

**AD.2007-03.4 Features Affecting the RAM Connection Design Mode**

Several new features have been added and existing features have been modified in the RAM Connection Design Mode. These are explained in the following pages.
Full use of the RAM Connection Mode requires access to a valid RAM Connection license. If you do not possess a license, contact your Bentley account manager to have it added to your SELECT licenses. Without a valid license, only a small subset of the full range of available RAM connections can be utilized.

AD.2007-03.4.1 Support of British Sections

To allow models created with British steel sections to be designed with RAM Connection, these sections need to be added to the supported US section database.

The ranges of supported sections are:

**US Sections**

Wide Flange
- W Shape - W
- M Shape - M
- S Shape - S
- HP Shape - HP

Tee
- Tees cut from W sections - WT
- Tees cut from S sections - ST
- Tees cut from M sections - MT

Channel
- Channel - C
- MC Channel - MC

Angle
- Angle - Equal and unequal, L and LU
  (Double angle, T2L and T2LU, but with fixed spacing)

Hollow
- Tube - TUBE
- Pipe - PIPE
- HSS Rectangular - HSS_RECT
- HSS Round - HSS_RND

Not supported
- B Shape
- Castellated
- Solid Round
- Cable

**British Sections**

UP Shape

AD.2007-03.4.2 Support of Multiple Connections at a Joint

RAM Connection designs separate parts of a connection with different templates such as a Shear Plate Connection and a Moment Connection. Therefore the RAM Connection mode has been enhanced to allow multiple Connections to be assigned to a single joint.

The following is an enhancement of the new feature added in STAAD.Pro 2007 Build 1001. Refer to AD. 2007-1001.5.1 RAM Connection Design Mode.

If a design brief is assigned to a joint that already has one assigned, then rather than replacing the existing design brief, an additional connection will be defined.
When multiple connections exist at a joint, the information is displayed such that the colour coding of the connection uses the following logic:
At least 1 connection?

yes

All connections have been designed?

no

Cyan

yes

All connections pass?

no

Yellow

More than 1 connection on the joint?

yes

Add No of connections to the joint

Green

When selecting a joint that has multiple connections associated with it, the following dialog box is displayed that shows the associated connections from which the required connection should be selected:

Note: Each connection is designed and detailed independently
The Software Release Report for STAAD.Pro 2007 Builds 01 + 02 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 build 1005. This document should be read in conjunction with all other STAAD.Pro manuals, including the Revision History document.

AD.2007-1001.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

AD.2007-1001.1.1 New Start Page

STAAD.Pro now includes a start page with access to the functions normally required when first starting STAAD.Pro, including shortcuts for starting a new file, accessing the recently accessed files, launching the help file and configuring STAAD.Pro.

The new Start Page is divided into 4 sections that can be used to achieve the following:

1. **Project Tasks**, to:
   - a. Start a New Project using the STAAD.Pro wizard.
   - b. Open an existing file using the traditional windows browse dialog enhanced with a model preview window.
   - c. Set the program behavior with the Configuration options.
   - d. Setup the automatic Backup configuration requirements.

2. **Recent Files** to preview and access the last 6 models opened.

3. **Help Topics**, to:
   - a. Quick access to the online Help document.
   - b. Locate the technical support centers and contact details.
c. Find out the latest information on the program online from the Product News link.

4. License Configuration. To quickly identify which SELECT licenses are being used by the current session of STAAD.Pro, they are displayed and color coded on the Start Page thus:

- If the license is available it is marked with a green circle thus:

- Licenses that have not been selected are marked with a grey circle thus:

- If the selected license can not be obtained or is not available from the server will be shown with a red circle, thus:

Additional configuration of the Bentley SELECT license, such as specifying the server name and activation key, can be viewed and set using Bentley License Management Tool which can be accessed from the link at the bottom right of the License Configuration section.

AD.2007-1001.1.2 Enhanced Grid Tool

The Snap/Grid Node tools have been enhanced to

1. Allow multiple different grids to be created.
2. Import a DXF file and use it as a template.
3. Import grid files created in another STAAD.Pro model

Beams, plates (both triangular and quadrilateral) and 8 noded solid elements can be generated using the appropriate Snap/Grid Node tool.

When this function is launched, the following dialog is opened which will include a Default Grid. This grid will be of type ‘Linear’, there are also options to create Radial, Irregular and imported DXF grids which will be described later.
As new grids are added or modified, the information is stored in the STAAD.Pro data folder with a GRD extension that allows other STAAD files to re-use these defined grids.

The effect of the current grid settings are displayed in the graphics window, thus:
To change the settings of this grid click on the **Edit** button to display the current grid properties, e.g:
The current plane of the grid is set by selecting the required option. This can be rotated about one of the global planes by selecting the axis of rotation and setting the angle.

The origin of the grid is marked on the graphics with a small circle:

![Image of grid origin](image)

The location of the origin, specified in global co-ordinates, can either be defined explicitly in the given X, Y and Z co-ordinates, or it can be set to the co-ordinates of an existing node by clicking on the icon,  (the cursor changes to  ) and then on the node itself in the graphical window. Note that at this point the origin co-ordinate is updated.

The construction lines are used to specify how many gridlines are created either side of the origin, the spacing between the gridlines and if there should be a skew in degrees along either axis.

Click on the **OK** button to accept these settings.

Additional grids can be defined by clicking on the [Create...] button. Three different types of standard grid can be created:

- Linear
- Radial
- Irregular

The type of grid required should be selected from the drop list of types available at the top of the property sheet. Each new grid should be identified with a unique name for future reference. The functionality for each type of grid is thus:

**Linear**

The Default Grid defined above is a Linear Grid and thus see above for the settings of a Linear Grid.

**Radial**

The settings for a Radial grid are defined in the following window:
The Plane, Angle of Plane and Grid origin options are as for the Linear (or Default Grid).

The construction lines options

**Start Angle**, is the angle in degrees about the orthogonal axis to the plane from the axis first referred to in the definition of the plane. For example, if the selected plane is X-Y, then the angle is measured about the Z axis (using the right hand rule) from the axis parallel to the X axis.

**Sweep** is the angle in degrees measured from the start angle which is divided into the selected number of Bays, thus:

---

*Irregular*

The settings for an Irregular grid are defined in the following window:
The origin is set as described above for both Regular and Radial grids.
The plane of the grid can either be set in one of the global planes X-Y, X-Z or Y-Z and rotated about one of the
global axes. This method is identical to that described for the Regular or Radial Grids. Alternatively, the
directions of the two axes can be specified as relative co-ordinates from the origin:

The gridlines are defined by the distance to the next gridline and the numbers separated with a space.
There are two import options that can be selected that can allow either DXF files or grids defined in another STAAD.Pro model (all but the default will be imported).

The option to import a DXF file will open the following dialog:

To select a DXF file click on the [...] button and navigate to the required file.

The file will be opened and displayed in the preview window. Individual layers can be turned on and off from the Layers droplist. The individual entities in the selected layers are displayed and can be toggled on or off for import.

By clicking on an entity in the graphical window, the entity is highlighted in the table so that it can be turned off if required.
With the required entities selected, a suitable reference name supplied and unit selected, click on the **Import** button.

The data will be imported in the plane in which it was defined in the original DXF. However, if required this can be rotated about any of the global axes. Also, the origin of the grid can be located at any 3D co-ordinate.

The option to Hide DXF text can be used to toggle the display of grid labels if they start clashing with the rest of the model. The grid is displayed thus (Note curved lines are currently not imported):
The DXF grid operates as the other forms of grid in that when the Snap Node/... button is clicked, nodes can be created at the ends and intersections of grid lines.

The second import option is to Import Grids previously defined in another STAAD.Pro model. Selecting this option opens a browse dialog box to identify a GRD file created by the Snap Node Grid tool. Note that GRD files are only created by STAAD.Pro 2007 (or later).

Icons on the Geometry toolbar are:

- Snap/Node Beam
- Snap/Node Triangular Plate
- Snap/Node Quadrilateral Plate

AD.2007-1001.1.3 Fly-out Toolbars

The amount of screen space occupied by a number of toolbar icons has been recovered by collapsing a number of similar icons into a single icon.

The active icon can be changed by holding down the left mouse button when clicking on the button. Icons that have this property are identified with a black triangle in their lower right corner:

There are four Geometry Toolbar icons that have this property:

- Add Beam
- Add Plate
- Add Solid
What's New?
STAAD.Pro 2007 Release Reports

- Snap Node Grid

The Add Beam icon supports four commands:
  - Add Beam from Node to Node
  - Add Curved Beam
  - Add Beam Between Mid Points
  - Add Beam Using Perpendicular Intersection

The Add Plate icon supports two commands:
  - Add Quadrilateral Plate
  - Add Triangular Plate

The Add Solid icon supports five commands:
  - Add 8 Noded Solid
  - Add 7 Noded Solid
  - Add 6 Noded Solid
  - Add 5 Noded Solid
  - Add 4 Noded Solid

The Snap Node Grid icon supports three icons:
  - Snap Node Beam
  - Snap Node Quadrilateral Plate
  - Snap Node Triangular Plate

AD.2007-1001.1.4 Physical Member Query

The addition of the Physical Member to the range of objects supported by STAAD.Pro requires that there is access to a query tool to get information about the Physical Member.

To access information on a Physical Member, use the Physical Member Selection Tool to highlight the required object and then select the menu option: Tools > Query > Physical Member to highlight the required object and then select the menu option:
This dialog box can also be accessed from

- Double clicking on a physical member with the **Physical Member Cursor**
- Selecting the physical member, right-clicking and selecting **Properties...** from the pop up menu.

**AD.2007-1001.1.5 In-Plane Area Loads on Plates**

STAAD.Pro can now apply plate loads in the local X and Y directions to represent in plane friction loads. As shown in the next figure, pressure on the full element can now be applied along local X and Y axes.

Thus a -2 kip/ft² load applied to an element that is 3 ft² will result in -6 kips being applied in the plane of the element.

This applies only to **Pressure on Full Plate**.

**Related Links**

- **TR.324.1 Area Load Specification** (on page 2665)
AD.2007-1001.1.6 Front-to-Front Channels

STAAD.Pro has been enhanced to support the definition of steel channel sections being defined in an arrangement with the toes pointing to each other with a given spacing.

![Front-to-Front Channel Diagram]

Front to front channel steel sections can be defined in the Properties dialog box by selecting the required channel section and choosing the **FR (Double Channel – Front to Front)** option and any spacing required between the channels.

The command that appears in the STAAD.Pro STD data file is:

```
<Member List> TABLE FR C4X5 SP 0.5
```

**Note:** The SP parameter is optional, but if it is not set, the section will *not* be assumed to be a closed box for torsional calculations.

AD.2007-1001.1.7 Automatic Property Calculations for User-Provided Table Angle Sections

User-Provided Tables (UPTs) of Angle sections require section properties that can now be calculated when the section dimensions have been defined.

Angle Section UPTs require the following data to be entered for each section:
What's New?
STAAD.Pro 2007 Release Reports

1. D, Depth of angle
2. WF, Width of angle
3. TF, Thickness of flanges
4. R, radius of gyration about principal axis, shown as r(Z-Z) in the AISC manual (see below). This must not be set to zero.
5. AY, Shear area along Y axis
6. AZ, Shear area along Z axis

Define the dimensions of the angle (shown in bold above):

Then click on the Calculate button to have STAAD.Pro calculate the remaining properties provided:
**AD.2007-1001.1.8 Consolidation of Multiple Property References**

When a STAAD file has a number of references of the same property, there is now a tool to consolidate all these properties into a single command.

STAAD models that have the same property defined multiple times can be consolidated by clicking on the new menu item, **Tools > Merge Properties**.

A warning is given and thus an opportunity to cancel the property collation if not required or selected by mistake.

All instances of a given section property will be collated into a single property reference.

**Notes:**

- Properties references with differing additional parameters will not be collated.
- Properties references with differing assigned material properties will not be collated.

**AD.2007-1001.1.9 Section Property Reduction in Analysis to Account for Cracking**

Concrete design specifications recommend the use of cracked section properties for the analysis and design of concrete sections. Though the methodology to handle cracked section properties is non-linear in nature, i.e. the section capacities should be checked and modified depending upon the section forces the section is handling. The model should then be re-analyzed with modified reduced section properties and redesigned. This iteration should be continued until the forces in all sections designed are below the allowable limit of ultimate strength.

In STAAD.Pro this approach has been simplified as per the recommendations in the ACI-318: 2005 standard which suggests a user input of reduction factors for the individual members. Section 10.11.1 of ACI-318 has provided a list of suggested reduction factors of section properties dependant upon the nature of stresses the member is subjected to.

An additional sheet has been added to the Beam Specifications dialog to allow the reduction of section properties for analysis to be created and assigned. The method is identical to that for creating any other beam specification.

The Specifications dialog can be accessed from the **General | Specifications Page** in the Modeling Mode:
The reduction factor should be a fraction of unity; hence a factor of 0.5 defined for RAX will reduce a defined cross sectional area of 0.5 ft\(^2\) to 0.25 ft\(^2\).

The format of the command that is generated in the STAAD.Pro STD file is:

```
MEMBER CRACKED
<Member List> REDUCTION { RAX | RIX | RIY | RIZ} factor
```

Multiple factors can be assigned on the same line.

**Note:** The reduction factor is considered only for analysis but not for design.
What's New?
STAAD.Pro 2007 Release Reports

AD.2007-1001.1.10 Tension/Compression-Only Spring Support

STAAD.Pro can now graphically define spring supports that are to allow tension only or compression only forces.

The Tension/Compression Only Support command is created from the Supports dialog box.

The Supports dialog can be accessed from the General | Support page in the Modeling mode.

Click on the Create button and select the Tension/Compression Only Spring sheet thus

The selection of Reaction Type indicates that if, after any of the cycles of analysis, the direction of the force in the spring is of the wrong 'type', then the support will be removed from that direction and a new analysis performed.

<table>
<thead>
<tr>
<th>Reaction Type</th>
<th>Tension Only</th>
<th>Compression Only</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support will remain if the reaction is</td>
<td>- ve</td>
<td>+ ve</td>
</tr>
<tr>
<td>Support will be removed and a new analysis flagged if the</td>
<td>+ ve</td>
<td>- ve</td>
</tr>
<tr>
<td>reaction is</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

What's New?
STAAD.Pro 2007 Release Reports

STAAD.Pro
User Manual
This support definition should be either ‘added’ to the Supports dialog (by clicking on the Add button) or assigned to the currently selected nodes (by clicking on the Assign button) that have previously been assigned with spring supports. If the support is not assigned as it is created, it can be assigned later from the Support dialog. However, note that if it is not assigned to at least one spring support when STAAD.Pro is closed, then the definition will not be saved in the STD file.

**AD.2007-1001.1.11 Enhanced Elastic Mat Plate Mat Options**

The Elastic Mat and Plate Mat commands can be set to behave as compression only springs and include the influence area that each node has been subjected to in the ANL output file.

In order to allow Elastic Mat and Plate Mat commands to perform as compression only supports to model lift of support situations, the command has been enhanced with an additional parameter which can be set graphically from the command definition.

The Elastic Mat and Plate Mat commands are created from the Foundation sheet in the Supports dialog box. The Supports dialog can be accessed from the General | Support page in the Modeling mode.
When the Compression Only option is set, then if after any of the cycles of analysis, the force at a node included in the command range (in the elastic mat range or used to define a plate in the plate mat range) is found to be tensile (i.e., negative reaction), then the load case is marked for a re-analysis with that support removed.

There is also a new option to include in the output file, the area that has been used in the calculation of the spring stiffness of each joint used when defining a Plate Mat or Elastic Mat command.

**Related Links**
- [TR.27.3 Automatic Spring Support Generator for Foundations](on page 2517)

**AD.2007-1001.1.12 Reference Load Cases**

Large models can include multiple load cases which do not require analysis in their own right and are simply the building blocks for inclusion in primary load cases. This is similar to a REPEAT LOAD command, but has the added benefit of not being solved in its own right.

A reference load case is listed in the Load dialog box of the General Load Page of the modeling mode. A Reference load case is listed in the Definitions section of the data file and displayed thus:
To add a new Reference load case, highlight the Reference Load Definitions in the Load dialog and click on the Add button. Provide the title for the load case and number (however, similar to that of creating Primary load cases, the next available reference load case number. Note that these reference load case numbers can be the same as a primary or combination load case number (however a combination load case number cannot be the same as a primary load case number).

The Reference load case names are shown in the Load dialog box. Load items should then be added to this load case in exactly the same way as adding load items into a primary load case.

Select the Reference load case and click on the Add button to display all the load items that can be added to this load case, thus:
To be analyzed, the loads defined in a Reference load case must be added to one or more Primary load cases. This is done by selecting the required primary load case and clicking on the Add button.

Select the load item **Repeat Load > Reference Load**: 

Select the required defined Reference load cases and click on the [>] button to select them for inclusion in the current load case. The >> button will select all defined Reference Load cases.

These are added with a factor of 1.0, however, each can be modified with its own specific multiplication factor:
The format of the definition of a Reference Load (i) in the data file is thus:

```
DEFINE REFERENCE LOADS
LOAD R(i) LOADTYPE (type) TITLE REF LOAD CASE 1
(LOAD items)
...
END DEFINE REFERENCE LOADS
```

The format of a reference to a Reference Load in a primary load (j) case is thus:

```
LOAD (j) LOADTYPE (type) TITLE LOAD CASE 1
REFERENCE LOAD R(i) 1.0
...
```

**Related Links**
- *Repeat Load tab* (on page 3028)
- *TR.31.6 Defining Reference Load Types* (on page 2642)
- *M. To create a reference load* (on page 873)

**AD.2007-1001.1.13 Enhanced Beta Angle Definition and Assignment**

Assigning beta angles on members has been improved visually by displaying the commands that are stored in the STAAD data file, making them easier to manage.

Beta angle definitions are created and listed in the Beta Angle sheet of the Property dialog box. Each new command is listed in the dialog as shown below and can be assigned using the assignment methods commonly used throughout STAAD.Pro:
The creation of beta angle commands includes three options:

1. Define specific angle to rotate the beams about their local X axis.
2. Specify the command ‘Angle’ (*)
3. Specify the command ‘RAngle’ (*)

(*) The Angle and RAngle commands are specifically for equal and unequal angle sections. All sections are aligned with their principal axes aligned with the global axes, however, angle sections are often required to align their flanges with the global axes. By assigning either the Angle or RAngle command, the section will be rotated to align the flanges. For more information, see section 5.26.2 - Specifying CONSTANTS for members, plate elements and solid elements - of the Technical Reference Manual (on page 2503).

Related Links

The static equivalent method for performing dynamic analysis per the IBC 2006 code has been implemented in STAAD.Pro 2007 Build 02.

This option can be accessed from the General | Load page as explained below.

When the General | Load Page is selected, the right hand side of the screen will display the following if no load cases exist in the model.

Definitions contains the options through which one creates the “Define” block of data required to create wind load cases, seismic load cases like IBC and UBC, moving load cases and time history load cases.

When the tree view is expanded, it will look as shown below.

Select Seismic Definitions and click on Add.

In the dialog box that comes up, select IBC 2006 from the drop-down list.
In this dialog box, we can specify the various parameters as described below.

**Include Accidental Torsion**
Check this box to calculate the accidental torsion component described in section 12.8.4.2 of ASCE 7-05.

**Parameter**
The various parameters for the IBC 2006 code, such as the Occupancy Importance factor IE, Response modification factors RX and RZ, spectral response accelerations SDS, SD1 and S1, etc., are described in detail in TR.31.2.12 IBC 2006/2009 Seismic Load Definition (on page 2592).

After specifying the values for the parameters, click on the Add button.
We will see that the Load dialog box has now been updated.
Next, we should define the structural weights for calculating Base Shear.

After highlighting the expression LAT 38.0165……, click on Add. A new dialog box titled Add New Seismic Definitions will come up.

Related Links
• M. To add a seismic load definition (on page 840)

This tab allows the user to apply response spectrum loads on the structure.
This option can also be accessed from the General | Load page.
Period vs. Acceleration

Provide the values of period (seconds) and corresponding acceleration (current length units/sec^2) or displacement (current length unit). Spectrum pairs should be provided in ascending value of period. As we provide the curve points, the program displays the curve at the bottom of the dialog box.

AD.2007-1001.2 Features Affecting the Analysis and Design Engine

The following section describes the new features that have been added to the analysis and design engine and existing features that have been updated or modified.
AD.2007-1001.2.1 P-Delta Analysis Including Stiffening Effect of the KG Matrix

The P-Delta analysis capability has been enhanced with the option of including the stress stiffening effect of the Kg matrix into the member / plate stiffness.

A regular STAAD P-Delta Analysis performs a first order linear analysis and obtains a set of joint forces from member/plates based on the large P-Delta effect. These forces are added to the original load vector. A second analysis is then performed on this updated load vector (5 to 10 iterations will usually be sufficient).

In the new P-Delta KG Analysis, that is, with the Kg option selected, the effect of the axial stress after the first analysis is used to modify the stiffness of the member/plates. A second analysis is then performed using the original load vector. Large & small P-Delta effects are always included (1 or 2 iterations will usually be sufficient).

The KG option is activated by selecting the option on the P-Delta Analysis dialog thus:

Related Links
- [A. To specify a P-Delta analysis](on page 928)

AD.2007-1001.2.2 P-Delta Analysis Including Small Delta

A regular STAAD P-Delta Analysis can now account for the small P-Delta effect whilst performing a P-Delta analysis.

Without the Small Delta option, i.e. a regular STAAD P-Delta analysis, STAAD performs a first order linear analysis and obtains a set of joint forces, from members/plates based on the large P-Delta effect, which are then added to the original load vector. A second analysis is then performed on this updated load vector.
With the Small Delta option selected, both the large & small P-Delta effects are included in calculating the end forces, (5 to 10 iterations will usually be sufficient).

The option is activated by selecting the option on the P-Delta Analysis dialog thus:

Related Links
•  *A. To specify a P-Delta analysis* (on page 928)

### AD.2007-1001.2.3 Buckling Load Analysis

STAAD.Pro can now identify the factor by which the loads in the selected load case should be increased (or decreased if less than 1) such that Euler buckling would occur.

Two methods have been introduced to do buckling analysis. One method is introduced in the standard solver, the other in the advanced solver, as described below.

**Related Links**

•  *A. To specify buckling analysis* (on page 932)

### AD.2007-1001.2.3.1 Buckling Analysis Using the Basic Solver

By including the command PERFORM BUCKLING ANALYSIS, the program will perform a P-Delta analysis including Kg Stiffening (geometric stiffness of members & plates) due to large & small P-Delta effects. If a non-singular stiffness matrix can be created, then buckling has not occurred. Then the load is increased from the last increment repeatedly until buckling does occur. Then the load is decreased halfway back to the prior increment. This bounds the buckling factor between the last 2 increments. Then STAAD proceeds to halve the interval until either the change between increments is 0.1% of each other, or the specified number of increments has been exceeded. The resulting factor is reported in the output file. The buckling deformed shape is simply the deformed shape from a static analysis with the near buckling load applied. This could appear more like a crushing, small displacement shape rather than a buckling mode shape. 15+ iterations are recommended.

Buckling will be applied to all primary cases.

The option is activated using the new option in the **Analysis/Print** dialog thus:
The results of the Buckling analysis are presented in the output file thus:

AD.2007-1001.2.3.2 Buckling Analysis Using the Advanced Solver

This buckling method is automatically activated if an Advanced Analysis license is available. When using the Advanced Solver, the corresponding ‘buckling modes’ are included in the output file. [See AD.2007-1001.2.6 Advanced Solver (on page 267) on the procedure to invoke the alternative standard buckling load analysis solver the use of which is explained in section AD.2007-1001.2.3.1 (on page 263) of this document]

The option is activated using the new option in the Analysis/Print dialog thus:
The program performs a P-Delta analysis including Kg Stiffening (geometric stiffness of members & plates) due to large & small P-Delta effects.

The eigensolution,

$$| [K] - BF [Kg] | = 0$$

is solved for the buckling factors and buckled mode shapes. The first 4 buckling factors and buckled shapes are calculated and included in the output file:

The buckling modes and shapes are available to be viewed in the Post Processing Mode in a new Buckling Page.
This page includes both a Buckling Factors table:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Buckling Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.426</td>
</tr>
<tr>
<td>2</td>
<td>2.855</td>
</tr>
<tr>
<td>3</td>
<td>4.747</td>
</tr>
<tr>
<td>4</td>
<td>4.802</td>
</tr>
</tbody>
</table>

and a Buckling Modes table:

Only the primary load case just prior to the PERFORM BUCKLING command is used. The number of iterations entered is ignored. The buckling factor result is reported in the output file and in post processing.

**AD.2007-1001.2.4 Modal Analysis Including Stress Stiffening Effect of KG Matrix**

STAAD.Pro can include the stress stiffening effect (geometric stiffness) based on the axial member forces/plate in-plane stresses from a selected load case when calculating the modes & frequencies of a structure.

Position the selected load case from which the axial stresses are to be used to modify the stiffness matrix, such that it is the last static case before the dynamic case which is in turn immediately followed by a PDELT A KG command.

The dynamic load case should contain mass data followed by one of the following:
a. A MODAL CALCULATION REQUESTED command.
b. A response spectrum definition, i.e., set of SPECTRUM command data.
c. A reference to a time history definition, i.e., include TIME LOAD commands.
d. Valid Steady State data.

Example

...  
LOAD 1 LOADTYPE None TITLE LOAD CASE 1  
******* This is static loading case from which the “axial stress” is

******* Note that dynamic cases use the factored matrix from the last *******  
load case; which is a (K+Kg) case  
MODAL CALCULATION REQUESTED  
PDELTA KG ANALYSIS

AD.2007-1001.2.5 Enhanced Master/Slave Command Processing

The internal processing of any Master Slave command has been enhanced to allow an automatic bandwidth reduction to take place.

The analysis engine now performs a bandwidth reduction on files that include Master/Slave commands which must occur in the input file after the definition of supports. In previous versions of STAAD.Pro, for the bandwidth reduction to take place, the data of Master/Slave would need to be repeated before the support definitions. This requirement is now no longer required.

Related Links
• TR.28.1 Master/Slave Specification (on page 2525)

AD.2007-1001.2.6 Advanced Solver

A new substantially faster analysis engine has been produced which can provide solutions of large structures in a fraction of the time currently required by the standard STAAD engine. The Advanced Solver generally uses less disk and memory as well.

The Advanced solver is a new addition to the STAAD Analysis Engine which can be used for solving both static and dynamic problems. It is part of the STAAD engine with no special command required to run it. It is automatically activated if a suitable license is available (*), however, this can be turned off and the standard solver used by including the option:

SET STAR 0
This command must be included in the header information block at the start of the file and before the first JOINT command block.

The engine can operate in two modes, *in-core* and *out-of-core*. The in-core solver will be used for models with under 20000 joints and the out-of-core solver for models over 20000 joints. In most situations, the in-core mode will provide the quickest solution, but where there is insufficient memory available, then the engine will use the out-of-core mode. Again, selection of the mode is automatically chosen by the analysis, but can be over-ridden.

The full set of overrides for the advanced engine is:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET STAR -3</td>
<td>use in-core solver regardless of size</td>
</tr>
<tr>
<td>SET STAR 4</td>
<td>use out-of-core solver regardless of size</td>
</tr>
<tr>
<td>SET STAR 3</td>
<td>default</td>
</tr>
<tr>
<td>SET STAR 0</td>
<td>use STAAD standard solver</td>
</tr>
</tbody>
</table>

**Notes:**

(*) To use this feature requires access to a ‘STAAD Advanced’ license. If you do not currently have this feature, please contact your account manager.

(**) Global Euler Buckling analysis is different between the two solvers. See AD.2007-1001.2.3 Buckling Load Analysis (on page 263) for the differences.

**AD.2007-1001.2.7 Eurocode 3:2005**

The latest UK release of *Eurocode 3: Design of steel structures – part 1-1: General Rules and rules for buildings* has been implemented.

This code is an update to our current Eurocode 3. The changes are minor and the code checking process remains the same as the previous Eurocode 3 design.

The design parameters are the same and apply as defined for the current Eurocode 3, the only exception, however, is the ‘Code’ parameter which must be set to ‘EC3 BS’. This setting is available form the GUI list of codes.

Note that a design performed to the new Eurocode 3 standard is displayed in the output file (*.ANL) with the following header:

```
STAAD.PRO CODE CHECKING - (BS EN 1993-1-1:2005)
**************************
PROGRAM CODE REVISION V1.1 BS_EC3_2005/1
```

The equivalent header for a code check (or member selection) to the older standard is displayed thus:

```
STAAD.PRO CODE CHECKING - (DD ENV)
**************************
PROGRAM CODE REVISION V1.14_EC3_94/1
```

**What's New?**

STAAD.Pro 2007 Release Reports

In AD.2007-1001.1.14 IBC 2006 Equivalent Lateral Force Procedure (on page 258), the graphical screens containing the implementation of the seismic loading chapters of the IBC 2006 and ASCE 7-05 codes were presented.

Related Links
- M. To add a seismic load definition (on page 840)

This command may be used to specify and apply the RESPONSE SPECTRUM loading as per the 2006 edition of the ICC specification "International Building Code (IBC)," for dynamic analysis. The graph of frequency–acceleration pairs are calculated based on the input requirements of the command and as defined in the code.

Related Links
- TR.32.10.1.8 Response Spectrum Specification per IBC 2006 (on page 2743)

AD.2007-1001.3 Features Affecting the Post-Processor (Results Mode)

A new feature has been added to the post-processor section of the program, also known as the Results Mode. It is explained in the following pages.

AD.2007-1001.3.1 Statics Check Table

The equilibrium check that has been available in the output file is now automatically included in the Post Processing Mode.

The Node | Reactions Page has been enhanced with a new table that displays the results of an equilibrium check. This is the same information that in the past would have been only available by including a PRINT STATICS CHECK in the perform analysis command.

The Statics Check Results table can be accessed from the Nodes | Reactions page in the Post-Processing mode.

AD.2007-1001.4 Features Affecting the Concrete Design Mode

The enhancement made in the RC Designer section of the program, also known as the Concrete Mode, is explained in the following pages.
AD.2007-1001.4.1 Beam and Column Designs to the Russian Concrete Code SP52

Two new design options have been added that allow concrete beams and columns to be designed to the Russian Concrete design code SP52-101-3.

The Russian Design Codes are only available with the **Euro-zone – Eastern Design Codes** SELECT license. The SP52-101-03 design checks are initiated by creating a design brief based on this code. This option is now available and can be selected when creating a new design brief. Beams and columns can be designed using design briefs tailored to the requirements of the specific item.

Design Briefs are created in the **Design Layer | Groups/Briefs** Page of the Concrete Designer mode. Click on the **New Brief** button on the base of the Design Brief Table:

![New Brief button](image)

**Beam Design Briefs**

An SP52 Beam design brief is created by setting the design brief options in the dialog that is presented when the **New Brief** button is clicked on the Design Briefs dialog:

![Beam Design Brief dialog](image)

The beam design brief contains two sheets of data that are used in the calculation of the reinforcement of any member that it is associated with. Default values are provided which should be changed to the specific values required for the design. These sheets are titled ‘General’ and ‘Reinforcement’ thus:
Column Design Briefs

An SP52 Column design brief is created by setting the design brief options in the dialog that is presented when the New Brief button is clicked on the Design Briefs dialog:
The column design brief contains three sheets of data that are used in the calculation of the reinforcement of any member that it is associated with. Default values are provided which should be changed to the specific values required for the design. These sheets are titled 'General', 'Reinforcement' and 'Member Loadcases' thus:
With the Design Brief created, Design Groups must be defined. These are created by selecting the design members that are required and clicking on the **New Design Group** button on the base of the Design Groups dialog:
What's New?

STAAD.Pro 2007 Release Reports

This pops up a dialog to allow the required Design Brief to be assigned to the selected design members that are now in this Design Group.

The group is added to the Design Group table and by double clicking on the group label, e.g. G1, then the list of members in the group is displayed and can be edited.

Note from here on, a suitable license is required to perform a design or review the results of a design.

To perform a design or review results of a previous design, requires entering the Concrete Member Mode by either clicking on the tab on the left of the screen or selecting Member Design from the Mode menu.

The program uses the Design Brief of the current Design Group to determine the page tabs and page layout that is now presented. The current Design Group is selected by choosing it from the drop-list of design groups displayed at the top of the screen.

*Beam Designs*

When the current group has a beam design group associated with it, entering the Concrete Member Mode, there are the following 7 pages:

- Summary
- Design
- Main Layout
- Main Reinforcement
- Shear Layout
What's New?
STAAD.Pro 2007 Release Reports

- Shear Reinforcement
- Cracks

The **Summary** Page displays the current status of the design of the members in the design group in a Summary table. Each member is identified with the principal checks including the span and section where the maximum utilization occurs. If any section cannot achieve a solution such that the design ratio is greater than unity, this is identified in red, thus:

![Summary Page example](image)

The **Design Page** is laid out in the same manner as the Summary Page but also launches the Design options dialog, where members from the design group can be selected or removed from the design process:

![Design Options dialog](image)

The **Main Layout** Page displays the design reinforcement for the current member selected from the design group drop list:
Note that the section arrow displayed on the elevation of the beam or the moment diagram, can be moved to display the reinforcement at any location along the beam.

By clicking on either the beam elevation or the cross section, then clicking on the 'Take Picture' toolbar icon, a picture will be added to the picture album which can be included in a User Report:

The **Main Reinforcement** Page displays the summary of the calculations at each of the design sections for both the maximum positive and negative moment at the given section for the current member.

The **Shear Layout** Page displays the shear reinforcement for the current member:
The Shear Reinforcement Page displays the summary of the shear reinforcement calculations at each cross section for the current member.

The Cracks Page displays the summary of the crack width check for both short and long terms and both maximum hogging and sagging moments:

Column Design

When the current group has a column design group associated with it, entering the Concrete Member Mode, there are the following 6 pages:

- Summary
- Input
- Design
- Main Layout
- Results
- Drawing

The Summary Page displays the current status of the design of the members in the design group in a Summary table. Each member is identified with the bars provided and a safety margin, thus:
The **Input** Page provides a table to set the effective length factors (enter b to reset to the value set in the brief), an indication as to whether either direction is braced and what size link bar is to be used thus:

The **Design** Page is laid out in the same manner as the Summary Page but also launches the Design options dialog, where members from the design group can be selected or removed from the design process:

The **Main Layout** Page displays the reinforcement layout in the column, including the shear links. For a typical rectangular or square column it is shown thus:
For a circular column it is shown thus:

The Results Page displays a table of the principal check for each column in the group thus:

The Drawing Page allows the current column details to be exported into a DXF file that can be used imported into a CAD package. Also a simple summary schedule of bars for the current member is displayed.
Printing Reports

Refer to the RC Designer manual (on page 1016) for more information on creating user reports.

Exporting to Bentley Rebar

Both beam and column designs can be exported to Bentley Rebar by selecting the menu option, Groups > Export Group to Rebar.

For more information, see ‘What’s New in STAAD.Pro 2006 Build 1004’ AD.2006-1004.4.1 Bentley Rebar Export from RC Designer.

AD.2007-1001.5 Features Affecting the Connection Design Mode

A new mode has been added that allows quick design of connections using the RAM Connection application. This is displayed on the Modes toolbar with the above icon.

Full use of the RAM Connection Mode requires access to a valid RAM Connection license. If you do not possess a license, contact your Bentley account manager to have it added to your SELECT licenses. Without a valid license, only a small subset of the full range of available RAM connections can be utilized.

AD.2007-1001.5.1 RAM Connection Design Mode

There is now a new mode in STAAD.Pro to dynamically link structural model data, including section properties and analysis results, to the RAM Connection application to check connection designs for code compliance. The resulting data and diagrams of the connection can also be included in the User Report.

Connections are designed in the RAM Connection Mode by creating ‘Joints’, from the geometry, section properties and forces resulting from the analysis and assigning a ‘Design Brief’ of connection templates from which a suitable connection, where available, is reported.
Refer to the D. Connection Design workflow (on page 953) for current details on this feature.

AD.2007-1001.6 Features Affecting the Piping Mode

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Piping Mode. These are explained in the following pages.

AD.2007-1001.6.1 Persistency of Pipe Models

When a pipe model is loaded in the Piping Mode, the location of the data is retained along with the connections defined in the Supports Page. Thus, if STAAD.Pro is closed and re-opened, it is no longer necessary to redefine the pipe model or the support relationships.

This feature is an enhancement of the functionality of the Piping Mode.

STAAD.Pro 2006 Release Reports

The Software Release Report for STAAD.Pro 2006 contains detailed information on additions and changes that have been implemented since the final build of STAAD.Pro 2005. This document should be read in conjunction with all other STAAD.Pro manuals.

STAAD.Pro 2006 Build 1004 Release Report

The Software Release Report for STAAD.Pro 2006 Build 1004 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 build 1002. This document should be read in conjunction with all other STAAD.Pro help.

AD.2006-1004.1 Features Affecting the Pre-Processor (Modeling Mode)

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modelling Mode. These are explained in the following pages.

AD.2006-1004.1.1 New AISC Unified Code

A new steel design code module has been added to STAAD.Pro, which allows steel beam sections to be designed to the rules defined in AISC specification, Specification for Steel Buildings, March 9 2005, ANSI/AISC 360-05. This is also referred to as the AISC Unified Code. The GUI has been updated to allow you to enter the design information for this new design code.

To perform a design of steel sections to the AISC Unified Code, a design parameter block containing the command CODE AISC UNIFIED followed by the command to perform a CODE CHECK or MEMBER SELECTION must be added to the STAAD.Pro data file.

The GUI has been updated by adding AISC UNIFIED in the Steel Design dialog:
When this design code option is selected, clicking on the Define Parameters button at the base of the dialog box will in turn open the Design Parameters dialog that will allow parameters to be added or added and assigned to specific steel members.

**Note:** Design to this module is only possible if your security allows design to US design codes.

**Related Links**
- *D1.A. American Codes - Steel Design per AISC 360 Unified Specification* (on page 1366)
- *AD.2006-1004.1.2 Update Indian IS 456 Concrete Code*

Two new parameters have been added to the IS 456 design code to assist in the design of concrete columns. ULY and ULZ are used to define the ratio of unsupported to actual column length about the local Y and Z axes.

To include the design parameters for a IS456 design check, click on the Design, Concrete Page, and select IS456 from the drop-down list in the concrete design dialog.

When this design code option is selected, clicking on the Define Parameters button at the base of the dialog box will in turn open the Design Parameters dialog that will allow parameters to be added or added and assigned to specific steel members.
The definition of the parameters and their default values are as defined below:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ULY</td>
<td>1.0</td>
<td>Ratio of unsupported length to actual length of column about minor axis.</td>
</tr>
<tr>
<td>ULZ</td>
<td>1.0</td>
<td>Ratio of unsupported length to actual length of column about major axis.</td>
</tr>
</tbody>
</table>

**AD.2006-1004.1.3 New NRC 2005 Seismic Code**

A new seismic definition module has been added to the STAAD.Pro Loading Definitions. This is to provide the user a tool to calculate and distribute the equivalent static loads produced by an earthquake that should be considered in a building as defined in the ‘National Building Code of Canada 2005 – Volume 1’, Section 4.1.8. This is also known as the NRC 2005 Seismic provisions.

This option has been added to be in addition to the previously available 1995 version of the code.

The NRC 2005 seismic provisions can be added using the **Seismic Definitions** dialog from the Definitions option in the main Load dialog box and selecting **CANADIAN NRC – 2005** from the type pull-down list.
Once all the required values for the parameters have been defined, then clicking on the Add button will add the data to the model such that it is ready to be used in seismic load cases.

For full details of the command structure for the NRC 2005 parameters see Section 5.31.2.11 of the Technical Reference manual (on page 2552).

Related Links
- TR.31.2.3 Canadian Seismic Code (NRC) – 2005 Volume 1 (on page 2552)
- AD.2006-1004.1.4 New Turkish Seismic Code

A new seismic definition module has been added to the STAAD.Pro Loading Definitions. This is to provide the user a tool to calculate and distribute the equivalent static loads produced by an earthquake that should be considered in a building as defined in the ‘Specifications for Structures to be Built in Disaster Areas. Part III – Earthquake Disaster Prevention. Amended on 2.7.1998, Official Gazette No. 23390 (English Translation)’. This is referred to as the Turkish Seismic Provisions.

The Turkish seismic provisions can be added using the Seismic Definitions dialog from the Definitions option in the main Load dialog box and selecting TURKISH from the type pull-down list.
Once all the required values for the parameters have been defined, then clicking on the Add button will add the data to the model such that it is ready to be used in seismic load cases.

For full details of the Turkish seismic load command structure see Section 5.31.2.12 of the Technical Reference manual (on page 2613).

Related Links
• TR.31.2.19 Turkish Seismic Code (on page 2613)

AD.2006-1004.1.5 Update Japanese Seismic Definition

The current version of the Japanese Seismic Loading Definition has been enhanced to allow the user to specify a value of ‘α (alpha)’, which is the ratio of frame height to the overall building height, which previously been set to 0.8 and not possible for the user to change.

The Japanese seismic provisions can be added using the Seismic Definitions dialog from the Definitions option in the main Load dialog box and selecting Japanese (AIJ) from the Type pull-down list.

Once all the required values for the parameters have been defined, then clicking on the Add button will add the data to the model such that it is ready to be used in seismic load cases.

Note: The implementation of the Japanese Seismic Definition is as per Article 88 in the ‘Building Codes Enforcement Ordinance 2006.’

For full details of the Japanese seismic load command structure see Section 5.31.2.4 of the Technical Reference manual (on page 2605).

Related Links
• TR.31.2.16 Japanese Seismic Load (on page 2605)

AD.2006-1004.1.6 New Eurocode 8 Response Spectrum

The provisions for Eurocode 8-2004 have been added to the Response Spectrum dialog box.
Enter the General, Loads Page of the Modelling Mode, and select the load case in the Load dialog box. Select the required load case name from the Load Case Details group and click on the Add button.

In the dialog box that is displayed, select the Response Spectra option from the list of items on the left and select the code Euro (EC8)-2004 to display the following:

![Response Spectrum dialog box](image)

Select the required parameters such as the Load Type and Combination Method and the direction that the spectrum is to be defined and click on the Add button to add the command to the input file.

**Note:** This is response spectrum definition has been provided in addition to the ENV 1998-1-1:1994 version of the code that was previously implemented. The older version of the code is still available, although recommended for comparison purposes only.

For a full description of both implemented versions of the Eurocode 8 Response Spectrum command structure, see Section 5.32.10.1.4 of the Technical Reference manual (on page 2715).

**Related Links**
- TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004 (on page 2715)
- M. To add an EC8 response spectrum (on page 849)

**AD.2006-1004.1.7 Update IS 1893 Dialog to Support Command Structure**

The Response Spectrum dialog for defining a Response Spectrum to be calculated as per the IS-1893 code by the analysis engine has been enhanced so that it reflects the input requirements of this command.

Enter the General | Loads Page of the Modelling Mode and select the load case in the Load dialog box. Select the required load case name from the Load Case Details group and click on the Add button.

In the dialog box that is displayed, select the Response Spectra option from the list of items on the left and select the code IS-1893. There are essentially 2 methods that can be employed to define the response spectrum:

1. Select a SubSoil Class
2. Define a Custom Reponse Graph
This choice is made from the **SubSoil Class** in the Spectrum Table. If a defined class is selected, then the Response Spectrum Graph is automatically defined and specified during the analysis, however the following dialog is presented to allow other options to be set:

![Response Spectrum Graph](image)

However, if a custom Response Spectrum Graph is required and selected from the SubSoil drop list, then the various points on the graph of period/acceleration or period/displacement must be entered, thus:

![Custom Response Spectrum Graph](image)

For a full description of the scope of the IS-1893 Response Spectrum command, refer to [Section 5.32.10.1.1 of the Technical Reference manual](on page 2721).

**Related Links**
- **TR.32.10.1.6 Response Spectrum Specification per IS: 1893 (Part 1)-2002** (on page 2721)
- **M. To add an IS 1893 response spectrum** (on page 846)
AD.2006-1004.1.8 Preview of Surface Element Meshes

Models that contain large numbers of surfaces, or have complex geometrical requirements can result in extensive analyses which may be unnecessary if appropriate settings are applied to the surface. In order to the mesh that will be generated during the analysis, the option to ‘Preview’ the surface meshes has been added.

After creating one or more surface elements, go to the Geometry, Surface Page which will display the Surface dialog. By clicking on the Preview button at the base of the dialog, the mesh that will be generated by the defined parameters will be displayed thus:
AD.2006-1004.1.9 Key File Option Added to Configuration Settings

The output file has the option to list all the key files that were used with the analysis including the date of the principal files. However, this can produce unwanted extra printout data and thus an option to specify whether or not this is to be used has been set in the Configuration Settings.

To access the File Configuration Settings, start STAAD.Pro, but close any open file or the New Wizard if it is open. Click on the menu option, File > Configure to open the Configuration Settings dialog and click on the sheet Input/Output File Format, thus:
To include the key file information in the output file, set the option **Add key file information to output**. If the option is set, the output file contains information similar to the following at the end of the file.

```
EXAMPLE PROBLEM NO. 1 -- PAGE NO. 18

Information about the key files in the current distribution

<table>
<thead>
<tr>
<th>Modification Date</th>
<th>CRC</th>
<th>Size (Bytes)</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>10/26/2006</td>
<td>0x3cc1</td>
<td>13266944</td>
<td>SProStaad.exe</td>
</tr>
<tr>
<td>10/25/2006</td>
<td>0x1cc0</td>
<td>05836800</td>
<td>SProStaadStl.exe</td>
</tr>
<tr>
<td>09/19/2003</td>
<td>0x2fc0</td>
<td>00081970</td>
<td>CMesh.dll</td>
</tr>
<tr>
<td>10/25/2006</td>
<td>0x4601</td>
<td>02486272</td>
<td>dbSectionInterface.dll</td>
</tr>
</tbody>
</table>
```

**Note:** If the general case is that the Key Information is displayed, it can be tuned off in a particular analysis if the data file contains the command `SET NOFILE`. 
AD.2006-1004.1.10 Load Icons Display Option

Certain models have large numbers of loads defined in any given load case. It is now possible to select which 'types' of load are displayed when the load case data is displayed.

To select which load items are displayed when the load is displayed, select the Options from the menu item View > Options and select Load Icons thus:

To return to the default of displaying all load types, click on the button Reset.

AD.2006-1004.1.11 Update Oneway Loading

The ONEWAY command has been enhanced with the option to define the direction in which the load is spanning by selecting a member in the loaded zone onto which the load is to be directed.

Enter the General | Loading Page and create or select the required load case.

Click on the Add button on the Load dialog box.

From the options on the left, select the Floor Load option and enter the Floor load in the normal way defining the direction, Load intensity and range. This defines a two way spanning system, to indicate a one-way span, click on the One Way Distribution option. This will then span in the shorter direction. However, now a beam number can be selected from the Towards drop list which is populate with the beams that exist in the defined range. As shown blow:
The selected beam is highlighted on the structure so that the spanning direction can be confirmed, thus:

Once the command is created, the load and contributing areas can be displayed by highlighting the command in the Load dialog box, thus:
By changing the beam number that defines the direction that the load is towards, the change in the loading can be viewed, thus:

AD.2006-1004.1.12 Additional Standard European Steel Section Types

Additional steel section shapes produced by European Steel manufactures have been added to the standard steel database libraries. Section shapes, HD, HL, UPE have been added.

Click on the General | Property page and on the Properties dialog box, click on the Section Database button to view steel section databases available. Click on the European label to view the section types that are now available.
AD.2006-1004.2 Features Affecting the Analysis and Design Engine

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

AD.2006-1004.2.1 AISC Unified Code

A new steel design code module has been added to STAAD.Pro, which allows steel beam sections to be designed to the rules defined in AISC specification, *Specification for Steel Buildings*, March 9 2005, ANSI/AISC 360-05. This is also referred to as the AISC Unified Code. The GUI has been updated to allow you to enter the design information for this new design code.

**Related Links**
- [D1.A. American Codes - Steel Design per AISC 360 Unified Specification](on page 1366)

AD.2006-1004.2.2 ACI 2005

The ACI concrete design module has been updated to support the current 2005 version of the ACI code, ACI 318-05.

When performing the concrete design using the parameter CODE ACI 2005, the design will be performed according to the requirements of the American Concrete Institute document, ‘Building Code Requirements for Structural Concrete (ACI 318-05)’. If it is required to perform the design to the older versions of the code, specifically, the 1999 or 2002 version of the code, then the commands:

```
CODE ACI 1999
```

or

```
CODE ACI 2002
```

The commands CODE ACI or CODE ACI 2005 will set the program ready to perform the design to ACI 2005 when it encounters the commands DESIGN BEAM..., DESIGN COLUMN..., or DESIGN ELEMENT...
For more information on the refer to the updated Section 3 of the Technical Reference manual, American Concrete Design (on page 1478).

AD.2006-1004.2.3 Enhancement of Indian Concrete Design

Two new parameters have been added to the Indian concrete design code, IS 456.

ULY and ULZ which are the unsupported lengths in the local Y and Z directions. These commands have been added to assist in the calculation of the minimum eccentricities.

Related Links
- D8.A. Indian Codes - Concrete Design per IS 456 (on page 1887)

AD.2006-1004.3 Features Affecting the Post Processing (Results) Mode

Several new features have been added and existing features have been modified in the Steel Designer section of the program, also known as the Steel Designer Mode. These are explained in the following pages.

AD.2006-1004.3.1 Unity Check Page Update

The Design Results table has been updated so that not only can the maximum utilisation ratio be displayed, but also the governing clause and combination. The superfluous section dimension information has been removed. Additionally, the table can be sorted by design ratio.

Perform an analysis and design and enter the Post Processing Mode. To view the Design Results table, click on the Beam | Unity Check Page. The table is displayed on the right of the window:

To sort the table by ratio, click on the Ratio column heading. To return to the un-sorted list, click on the Beam column heading.

AD.2006-1004.3.2 View Value Annotation Enhanced

The annotation of forces and displacements has been enhanced to allow the number of decimal places viewed on the diagrams to be configured.
1. Open a model with analysis results or run an analysis to obtain a set of valid analysis results.
2. Enter the Post Processing mode and click on the Beam | Forces Page to display the bending moment on the graphic view of the structure.
3. Click on the menu item Results > View Value... to annotate the bending moment diagram and define the items that are required to be annotated in the Ranges sheet, the list of items to be annotated such as Maximum Bending Moments.

4. To change the configuration,
AD.2006-1004.4 Features Affecting the Concrete Design Mode

Several new features have been added and existing features have been modified in the RC Designer section of the program, also known as the Concrete Design Mode. These are explained in the following pages.

AD.2006-1004.4.1 Bentley Rebar Export from RC Designer

When a design has successfully been carried out, the beams or columns may now be exported to Bentley Rebar from the **Groups > Export Group To Rebar** menu item. This will write the member outline and designed bars into a file for transfer into Bentley Rebar so that any modifications that a detailer feels are appropriate may be made. Bentley Rebar is a much more powerful detailing environment and can produce customised drawings and reinforcement schedules.

1. Open a suitable concrete model (such as Examp08.std) and perform an analysis if there are no analysis results available.
2. Select the Concrete Design Mode and create design members, a Design Group with a suitable Design Brief. Full details on the setup process can be found in the **RC Designer Manual, section 2 Getting Started** (on page 1007).
3. Enter the Concrete Member Mode of the RC Designer and perform a design.
   Note that members that can be successfully designed are color coded green, thus
4. Any of the members that produced a satisfactory design can be exported into a neutral file by clicking on the menu item: **Groups > Export Group to Rebar**.

All the valid designed members are displayed and those that are wanted for detailing should be listed in the 'Selected' column. Those that are not wanted should be moved into the 'Available' column. Once the list is correct, click on the [Export] button to create a 'Bentley Rebar Link File that has the file extension; .BRL
5. Start Bentley Rebar and open a suitable DGN file.
6. From the run the menu command: **Applications > GEOPAK REBAR > Menu**.
   This adds a new Rebar menu.
7. To import the RC Designer Group, click on the menu command: **Rebar > Tools > STAAD Detailing**.
   This opens the STAAD manager dialog from which Templates can be defined to describe how members that
   are imported are defined:

   ![STAAD Manager dialog](image1)

   and allows link files to be imported and located on the DGN file:

   ![STAAD Manager dialog](image2)
What's New?
STAAD.Pro 2006 Release Reports

Note: MicroStation and Bentley Rebar are separate products from STAAD.Pro and are independently licensed. If you do not have copies of these products, please contact your STAAD.Pro provider.

AD.2006-1004.4.2 Addition of Amendments 1,2, and 3 to the BS 8110 Modules

Due to the withdrawal of BS 5328 and its replacement by BS 8500, the terminology for concrete has changed from “grade” to “strength class”, and this is reflected in the design briefs. Also, due to harmonisation with European steel codes, Grade 500 high yield steel is now the standard, instead of Grade 460. The main changes in the British Standard were to change the partial safety factor for steel to 1.15 instead of 1.05. To allow older designs to be checked, the program now allows you to specify both the steel strength and the partial safety factor to be used.

Designs performed using the BS 8110 Beam, Column, or Slabs briefs will be as per BS 8110 with inclusion of these amendments. Note also that the default steel grade is now 500 N/mm² instead of 460 N/mm².

AD.2006-1004.5 Features Affecting the Piping Mode

STAAD.Pro can utilise the pipe layout and reactions created in the applications ADLPipe or AutoPipe. The pipe model can be imported in the Piping Mode. The following describes the method of using the Piping Mode and features recently added to this mode.
AD.2006-1004.5.1 Update of Importing Piping Models

The import stage of the Piping Mode has been enhanced by allowing the user to better relate the co-ordinate systems used by the two models, the structural model and the piping model. There are two issues that are addressed:

a. Locating the origin

b. Allowance for Y or Z axis as vertical in the piping model

Enter the Piping Mode by either selecting the menu option **Mode > Piping** or from the Mode Bar thus:

This displays the principal page and two sub pages available in this mode thus:

To select a pipe model to import, click on the **Open File...** button in the Information dialog box and navigate to the folder that has the required ADLPIPE or AutoPipe (*.ADI) model. Select the required file and click on the **Open** button. The following dialog is then displayed:

This allows the direction that was used as vertical in the pipe model system to be identified by clicking the option **Consider Z as the gravity axis for the Pipe Model** if required. Additionally, the X, Y, and Z values allows the origin of the pipe model to be placed at a different location than the origin of the STAAD.Pro structure.

Refer to the **Piping Mode section** (on page 878) in the User Interface help

AD.2006-1004.5.2 Pipes Support by Member

Supports defined in the piping model may not have corresponding nodes defined in the STAAD.Pro model. Therefore the pipe support function has been enhanced to allow members to be selected so that the support load will be transferred as a member load rather than node load.

Enter the Piping Supports page. Select the menu item 'Support>Support Node'. Using the Pipe Support cursor, select the pipe support node then click on the supporting member.
AD.2006-1004.6 Additional STAAD.Pro 2006 Build 1004 Features

The following pages outline the additional features that have been added to STAAD.Pro in this version.

AD.2006-1004.6.1 Modifications of the SELECT XM Security System

With the SELECT security system, STAAD.Pro can be configured to use either a **STAAD.Pro** license or a **Universal Structural License** (USL), which can also be used to access other structural products in the Bentley portfolio. However, to perform a design, the USL needs to be configured along to specify which design code packs are to be accessed during the operation of STAAD.Pro. Additionally, once the configuration of the STAAD.Pro SELECT license has been established, it is now possible to review the current settings and update it as required.

To review and/or update the current STAAD SELECT security configuration, click on the Start menu item: **Start > Programs > STAAD.Pro 2006 > Select License Tools > STAAD SELECT Configuration**
1. Select STAAD.Pro from the Product drop list.
2. Select whether a Standard or USL license should be obtained to run STAAD.Pro.
3. Select which code packs should also be obtained when STAAD.Pro is run.

Notes:

1. This configures what licenses are to be obtained. This does not confirm that those features are available. To confirm what features are available, click Settings. This launches the License Management Tool which displays the list of products and licences available on the currently defined SELECT XM server and those that are currently 'Checked Out' onto the local machine.
2. If a feature or design code requires a specific license during a session of STAAD.Pro, then it is important to check that the license for that feature is available using the License Management Tool and setting the STAAD SELECT XM License Configuration to obtain that license as STAAD.Pro starts.

For a complete description of the SELECT security system, please refer to the Quickstart & Troubleshooting Guide (STAAD.Pro_InstallGuide_en.pdf) document distributed with the installation setup.

AD.2006-1004.6.2 AISC N690

In addition to the standard ASD design method, STAAD.Pro can perform a design to incorporate the design requirements of Supplement No. 1 to the Specification of the Design, Fabrication and Erection of Steel Safety-Related Structures for Nuclear Facilities ANSI/AISC N690 – 1994s1. This additional code has been added to the Steel Design dialog.

To perform a design of steel sections to the AISC N690, a design parameter block containing the command CODE AISC N690 followed by the command to perform a CODE CHECK or MEMBER SELECTION must be added to the STAAD.Pro data file.

The GUI has been updated by adding AISC N690 in the Steel Design dialog:
When this design code option is selected, clicking on the Define Parameters... button at the base of the dialog box will in turn open the Design Parameters dialog that will allow parameters to be added or added and assigned to specific steel members.

For a full explanation of the features of the design engine see D1.K. American Codes - Steel Design per ANSI/AISC N690 Design Codes (on page 1575).

**Note:** Design to this module is only possible if your security allows design to US Specialised design codes.

**STAAD.Pro 2006 Build 1002 Release Report**

The Software Release Report for STAAD.Pro 2006 Build 1002 contains detailed information on additions and changes that have been implemented since the release of STAAD.Pro 2006 build 1001. This document should be read in conjunction with all other STAAD.Pro help, including the Revision History document.

**AD.2006-1002.1 Features Affecting the Pre-Processor (Modeling Mode)**

Several new features have been added and existing features have been modified in the pre-processor section of the program, also known as the Modeling Mode. These are explained in the following pages.

**AD.2006-1002.1.1 Automatic calculation of the Response Spectrum as per IBC**

STAAD.Pro previously allowed response spectra to be defined by the user, or calculated as per the Indian IS 1893 or Eurocode EC8.

The graphical user interface (GUI) has been enhanced so that it can now automatically generate a response spectrum as per the guidelines of the IBC/ASCE code.
(*) This new feature saves users the time and effort involved in establishing the 1 second and short period accelerations indicated in the IBC/ASCE maps and then converting them into spectral data based on the equations provided in the code.

The user enters the latitude and longitude (or select a US zip code), STAAD.Pro then establishes the site coefficients, S1 and SS. The user then selects the appropriate site class (A-F) and with this information, STAAD.Pro calculates the MCE spectral acceleration and design spectral acceleration as per sections 11.4.3 and 11.4.4 of the ASCE7-05 code. Finally the design response spectrum will be generated based on section 11.4.5 of the ASCE7-05 code.

Note: There is no change to the input command structure.

Description

Go to the General | Load page and in the Load dialog box, open the Load Case Details and select the appropriate primary load case with the masses (defined as load items) defined or create a new primary load case and add the masses, if required. Click on the Add button which will bring up the Add New: Load Items dialog box. Select the Response Spectrum option from the list on the left.

With the code option set to Custom, a Generate IBC Spectrum button will now be available as shown thus

Click on the Generate IBC Spectrum button to open the Spectrum Parameters dialog box thus
Refer to **Spectrum Parameters dialog** (on page 3027) for details on the input fields in this dialog.

To complete the generation of the IBC response spectrum pairs, click on the Close button. The completion of the Response Spectrum command continues as for all other Custom defined Response Spectrum commands. Note that the details of the spectrum Period, Acceleration pairs are displayed in the Response Spectrum window, but cannot be modified at this time.

For more details on the Response Spectrum loading command, refer to Section 5.32.10.1 of the Technical Reference Manual (on page 2688).

**AD.2006-1002.1.2 Enhancement to Physical Member Query Window**

With the enhancement of the physical Member in the Pre-Processing Mode, the Query dialog box obtained when a physical member is double clicked.

Select a Physical Member by using the Physical Member cursor, \[\text{Physical Member cursor} \] and double-click on that to view the **Physical Member Query** dialog box.

**Pre-Processing Information**

Prior to any analysis being performed, the physical member information available is displayed in the following three sheets **Geometry**, **Property**, and **Loading**.

All those common physical member attributes, assigned to that particular physical member (i.e., to all the analytical members comprising that physical member) are displayed in these information fields, as shown below:
Post Processing Information

If an analysis has been performed and there are results available, the following post processing results are made available in two additional sheets Shear Bending, to view the Shear Force diagram, Bending Moment Diagram, and Deflection to display deflected shape information.

Note: The design of Physical Members is only performed in the Steel Design Mode and note the batch method in the current version of STAAD.Pro.

Related Links
• Physical Member dialog (on page 3190)
AD.2006-1002.1.3 AASHTO (LRFD) Design Code

The STAAD.Pro analysis and design engine has been enhanced with the addition of a new design code, AASHTO (LRFD). The Graphical User Interface (GUI) has been updated to allow the design parameters to be entered and applied as required.

Go to the Design | Steel page and in the Steel Design dialog box, select the option AASHTO (LRFD) from the Current Code drop-list. Click on the button Select Parameters to display the parameters available to be used with this design code. With all parameters displayed in the right Selected Parameters’ panel, close the dialog box. Click on the Define Parameters to set the values for the parameters which can be added or assigned to selected members.

Click on the Commands button to add or assign the commands to the file to instruct a check or selection of sections based on the parameter settings.

The AASHTO design parameters listed in previous versions of STAAD.Pro as AASHTO in the Current Code drop-list of the Steel Design dialog box, have been renamed as ‘AASHTO (ASD)’

Note that access to design codes is controlled by your licence agreement and security settings. Not all users have access to all design codes. If this code is unavailable, see your STAAD.Pro supplier to obtain the updates needed to activate this or any other design code.

AD.2006-1002.1.4 Node Precision

A number of models require a higher than usual precision on the node co-ordinates that are used by the analysis engine.

With STAAD.Pro running, but without having any structural model loaded, select File > Configure.

In the resulting dialog, click on the Input File Format sheet, there is a new section Significant Digits which allows the required value to be set.

**AD.2006-1002.1.5 User Steel Table - Double Angles**

To design a beam that has been defined as a Double Angle from a User table, then an 11th parameter must be provided in the section parameters which defines the RVV value. The GUI has been enhanced to support this additional parameter.

**Description**

Select **Tools > Create User Table**.

Start a new table which is of type **DOUBLE ANGLE** and click on the **Add New Property** button which will display the following dialog which allows the value of Rvv to be included in the section property definition.

**AD.2006-1002.2 Features Affecting the Analysis and Design Engine**

The following section describes the new features have been added to the analysis and design engine and existing features that have been updated or modified.

**AD.2006-1002.2.1 AASHTO Design Code**

The STAAD.Pro analysis and design engine has been enhanced with the addition of a new design code, AASHTO (LRFD).

**AD.2006-1002.2.2 Updated Parameters on Indian IS 1893 Static Seismic Loading Command**

The static equivalent method for creating loads as per the Indian seismic code, IS 1893 has been enhanced with the option for checking soft stories.

**Related Links**

AD.2006-1002.2.3 Updated Parameters on Indian IS 1893 Response Spectrum Command

The method for creating a response spectrum to the Indian seismic code, IS 1893 has been enhanced with the option for checking soft stories and documentation on the torsion option added.

Related Links
- TR.32.10.1.6 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2721)

AD.2006-1002.3 Features Affecting the Steel Design Mode

Several new features have been added and existing features have been modified in the Steel Designer section of the program, also known as the Steel Designer Mode. These are explained in the following pages.

AD.2006-1002.3.1 Access to Physical Members Created in Pre-Processing Mode

Physical members can be created in the Pre-Processor mode and their definition stored in the STAAD.Pro input file (*.STD). Physical members that have been created in the Pre-Processing Mode are now available in the Steel Designer Post Processing Mode. Previous versions of STAAD.Pro would require these members being re-defined in the Steel Designer Mode.

Create Physical Members as defined in the manual AD.2006.1.1 Physical Member Interface (on page 313). Perform an analysis and enter the Steel Designer Mode. Go to the Member Design | Member Setup Page, and note that the members that were created in the Pre-Processing Mode are ready to be utilised in the Steel Designer Mode.

AD.2006-1002.4 Features Affecting the Concrete Design Mode

Several new features have been added and existing features have been modified in the RC Designer section of the program, also known as the Concrete Design Mode. These are explained in the following pages.

AD.2006-1002.4.1 DXF Output of Beam and Column Designs

It is now possible to write the completed design drawing to a raw DXF file, as well as to MultiREBAR format, so that it may be finished off by a detailer. The MultiREBAR format drawing requires a suitable installation of the MultiSuite application to visualize the drawing. The raw DXF format can be viewed by any application that can view DXF files.

Click on the Drawing or Schedule page (according to design code), a dialog opens as shown below, except for the addition of a drop list to choose the output format.
The MultiREBAR export remains as before, the DXF format is new. For DXF output, the concrete outlines, covers and center lines are all output as simple lines to appropriate layers. The bars are sent as polylines, again to separate layers. The schedule is not exported, but may be printed from the normal report setup. In all other respects the dialog works in the same way as described in the RC Design help (on page 1188).

Related Links
•  D. Export to Drawing dialog (on page 1188)

AD.2006-1002.5 Features Affecting the Advanced Slab Design Mode
The Mode previously known as the ADAPT Slab design has been redefined as the Advanced Slab Design and has been enhanced to support integration with RAM Concept.

Note: Beginning with STAAD.Pro CONNECT Edition, direct export to ADAPT-Builder® has been deprecated.

AD.2006-1002.5.1 Advance Slab Design Mode
Refer to the Advanced Slab Design Mode section (on page 1353) of the User Interface help for details.

AD.2006-1002.6 Features Affecting the Piping Mode
STAAD.Pro can utilise the pipe layout and reactions created in the applications ADLPipe or AutoPipe. The pipe model can be imported in the Piping Mode. The following describes the method of using the Piping Mode and features recently added to this mode.

AD.2006-1002.6.1 Piping Mode
Refer to the Piping Mode section (on page 878) in the User Interface help.
AD.2006-1002.6.2 3D Rendered View of Piping Model

In order to perform quick, visual clash detections, the 3D properties of the piping model have been added to the 3D section view and Rendered 3D View.

To view the solid 3D shapes in the graphical window, select the menu option, View > Structure Diagrams... This opens the Diagrams dialog in the Structures sheet. In the 3D Sections group, select the option ‘Full Sections’ to display a solid 3D shape of the structure model and piping arrangement, thus:

To view a rendered 3D view of the structural model with the piping arrangement, select the menu option, View > 3D Rendering... This creates a new window and displays a 3D perspective view of the model and piping thus:

Note: The piping model is only displayed in the Piping Mode.

AD.2006-1002.7 Additional STAAD.Pro 2006 Build 1002 Features

The following pages outline the additional features that have been added to STAAD.Pro in this version.
AD.2006-1002.7.1 Modifications in REI Security System

For details on the current security system for STAAD.Pro, please refer to the STAAD.Pro Installation Guide (STAAD.Pro_InstallGuide_en.pdf).

AD.2006-1002.7.2 Online Help

In order to assist the user operate STAAD.Pro, a number of context sensitive links have been added to the GUI such that clicking on a Help button or pressing the <F1> key will go directly to an appropriate help topic within the online documentation.

STAAD.Pro 2006 Build 1001 Release Report

The Software Release Report for STAAD.Pro 2006 Build 1001 contains detailed information on additions and changes that have been implemented since the final build of STAAD.Pro 2005. This document should be read in conjunction with all other STAAD.Pro help.

AD.2006.1 Features Affecting the Pre-Processor

Several new features have been added and existing features have been modified in the pre-processor section of the program. They are explained in the following pages.

AD.2006.1.1 Physical Member Interface

STAAD.Pro will allow grouping analytical predefined members into physical members using a special member group PMEMBER. PMEMBER defines a group of analytical collinear members, with same cross section and material property.

To model using PMEMBER, one needs to model regular analytical members and the start grouping those together.

While creating a PMEMBER, the following are the pre-requisites,

- Existence of the analytical members in the member-list.
- Selected members should be interconnected.
- The selected individual members are collinear.
- Local axis of the individual members comprising the physical member should be identical (i.e., x, y and z are respectively parallel and in same sense).
- A member in one Physical Member Group should not occur in any other Physical Member Group.

Related Links

- TR.16.2 Physical Members (on page 2443)

General Format

PMEMBER can be created either in modeling mode or Steel-Designer mode. Modeling mode and Steel-Designer mode physical members will be labeled as M and D, respectively. Modeling mode PMEMBER will allow variable cross-sections. Steel-Designer mode will allow importing PMEMBER-s created in modeling mode.

General Format
Following STAAD commands related to PMEMBER are implemented.

```
DEFINE PMEMBER
PMEMBER PROPERTY
PMEMBER CONSTANT
PMEMBER LOAD
PRINT PMEMBER FORCE
```

To define a Physical Member, the following command is used after the MEMBER INCIDENCE Command:

```
DEFINE PMEMBER
member_list PMEMBER pmember-no
```

Example

```
JOINT COORDINATE
1 0 0 0 6 10.0 0 0
MEMBER INCIDENCE
1 1 2 5
DEFINE PMEMBER
1 TO 5 PMEMB 1
```

To define the member property of a Physical Member, the following command is used:

```
PMEMBER PROPERTY
pmember-list PRIS ...
```

The Physical Member supports all types of member properties available in STAAD.

If multiple definitions of member properties for a particular analytical member is encountered (e.g. analytical member properties is defined twice, once via PMEMBER PROP command and again via MEMBER PROP command, then MEMBER PROP command will override PMEMBER PROP definition.

To define the Material constants of a Physical Member, the following command is used:

```
PMEMBER CONSTANT
E CONCRETE pmember-list
DEN CONCRETE pmember-list
...
```

Any member, which is a part of any PMEMBER is not allowed to be assigned constants explicitly.

**Note:** Loads are applied directly to PMembers using the PMEMBER LOAD command. See “PMember Load Specification” for details.

After the analysis, the Post Analysis results of a PMEMBER can be seen by using the following command:

```
PRINT PMEMBER FORCE
```

This command will produce member forces for all the analytical members in the group.

**Graphical User Interface for Physical Member**

The following steps are to be followed for creation of a Physical Member

Post-Processing Features Related to Physical Members

In the post processing results, to view the Shear Force diagram, Bending Moment Diagram and Deflected shape, use the member query dialog box.
Select a Physical Member by using the Physical Member cursor, and double-click on that to view the member query dialog box.

Design of Physical Members

In the current version of STAAD.Pro, the design of a Physical Member is not handled.

To Create a Physical Member

Make a frame model in STAAD.Pro, comprising of two or more consecutive beams.

1. Select two or more colinear, interconnected beams in the model.
   Refer the pre-requisites of the analytical members for details.
2. Either:
   - Select the **Form Member** tool in the **Physical Member** toolbar
   - Right-click and select **Form Member** from the pop-up context menu.

The details of the formed Physical Member can be seen in the **General | Physical Member** page at the right pane of the window.

To assign properties to a physical member

You must first create one or more physical member properties and then these can be assigned to physical members.

1. Select the **General | Property** page.
2. Select the **Toggle Physical Member mode** tool in the **Physical Member** toolbar.
3. Create a physical property:
   a. In the **Properties - Whole Structure** dialog, click **Define**.
      The **Property** dialog opens.
   b. Select a property class and define the required property parameters.
   c. Click **Add**.

A new property is added to the list in the **Properties - Whole Structure** dialog. This property is marked as “Physical”.
4. Assign this property to the physical member.

**Note:** For a Physical Member whose physical member property is already assigned, the individual analytical members in that Physical member will adopt the same member property that of the physical member. However, in case, where the analytical member property is assigned to any member in that physical member, then this analytical member property will supersede physical member property.

To assign specifications to a physical member

Only the Release, Offset, and Truss member specifications are available for physical members.

1. Select the **General | Spec** page.
2. Select the **Toggle Physical Member mode** tool in the **Physical Member** toolbar.
3. Create the member specification:
   a. Click **Beam** in the **Specifications - Whole Structure** dialog.
      The **Member Specification** dialog opens.
b. Select the dialog tab corresponding to the specification type you want to add.
c. For Release or Offset specifications, specify the parameters to define the specification.
d. Click Add.

A new specification is added to the list in the Specifications - Whole Structure dialog. Release and Offset specifications are marked as "Physical" whereas Truss specifications are labeled PMEMBER TRUSS.

4. Assign this specification to the physical member.

**Note:** For a Physical Member whose physical member specification is already assigned, the individual analytical members in that Physical member will adopt the same member specification that of the physical member.

However, in case, where the analytical member specification is assigned to any member in that physical member, then this analytical member specification will supersede physical member specification.

To assign loads to a physical member

1. Select the General | Load & Definition page.
2. Select a load case in the Load & Definition dialog and click Add.

Physical member loads can be assigned to a new or existing load case.

The Add New : Load Items dialog opens.

3. Select the Physical Member Loads tab.
4. Specify the load item parameters for a load type and click Add.

The load item is added to the load case and is marked as "Physical".

5. Assign the physical load items to physical members.
**Note:** For a Physical Member whose physical member Load is already assigned, the individual analytical members in that Physical member will adopt the member loads internally depending on the physical member load. However, in case, where the analytical member Load is assigned to any member in that physical member, then this analytical member Load will superimpose on the physical member Load.

### AD.2006.1.2 Load Envelopes

Load page will allow creation of Envelopes that can be saved as part of the STAAD input file. The user will be able to define multiple load envelopes each consisting of groups of predefined load cases. These envelopes can latter be used for post-processing. For example post analysis results may be viewed for a selected load envelope. As far as the STAAD engine is concerned, ENVELOP command will translate in to a LOAD LIST command.

The envelope can be tagged with optional key words to specify qualitative nature of the load or load combination cases included in the envelop definition. Based on the nature of the load cases in the envelope, the users can define appropriate design parameters for each envelope. For example, for design under wind load condition, most of the design codes allow increase of allowable stresses. Design routine can increase the allowable stress used in interaction equation, when it does the design for the envelope. Another application of this feature can be to specify separate load groups for serviceability check, working stress and limit state checks.

### Description

The option for defining **Load Envelopes** appears within the **Load** dialog box in the **General | Load** page as shown in the next figure.

![Load Envelopes Dialog Box](image)

To define an envelope, select the Load Envelopes and click on the Add button and the Add New : Load Envelopes dialog box will come up as shown in the next figure.
The Envelope will be identified by the number that appears in the Envelope edit box. One can select an appropriate type for the load envelope like stress, serviceability etc. depending on the nature of the loads selected for the envelope. All the predefined primary load cases and combination cases will appear inside the Available window. One can now select one or more of these cases, bring them to the Selected window on the right hand side and click on the Add button to create the envelope. Once an envelope is created, it will be displayed in the Load dialog box as shown in the next figure.

In the post processing mode, the Results Setup dialog box will include option for selecting Defined Envelopes for the purpose of displaying results as shown in the next figure. Once an envelope is selected the corresponding loads can be seen within the Selected window.
General Format

The load envelope commands are written in the STAAD input file as shown below.

```
DEFINE ENVELOP
  load-case-list ENVELOP # TYPE { NONE | STRESS | SERVICEABILITY | COLUMN | CONNECTION | STRENGTH }
END DEFINE ENVELOP
```

**Example**

```
DEFINE ENVELOP
  1 2 ENVELOP 1 TYPE SERVICEABILITY
  3 5 ENVELOP 2 TYPE STRESS
END DEFINE ENVELOP
```

The first line within DEFINE ENVELOPE command means that load cases numbered 1 and 2 make up the serviceability type load envelope 1. Similarly load cases 3 and 5 define the stress type load envelope 2.

To print out the support reactions corresponding to load envelope 1, that includes load cases 1 and 2, the following commands will be defined in the input file

```
LOAD LIST ENV 1
PRINT SUPPORT REACTIONS
```

If ENV keyword is encountered, the list will be interpreted as list of envelopes rather than a list of load cases.

**Note:** Please refer to the example file Load_envelopes.std, which is available under the different country folders.

**Related Links**

- *TR.40 Load Envelope* (on page 2837)
AD.2006.1.3 Persistency of Parametric Mesh Model in STAAD Input File

In the past, once the parametric mesh model was merged with the base model, no information about the parametric mesh was retained by STAAD. So, if any modification was required at a later stage, the parametric mesh had to be created afresh. Parametric model feature has now been enhanced and multiple parametric mesh models can now be saved as part of the STAAD model. This would allow the users the flexibility to come back to the saved mesh models at any time and make modifications to it like adding an opening or adding a density line.

The parametric mesh model data is now saved as part of the STAAD input file. Special tag based commands has been introduced to support saving of parametric mesh models as part of the STAAD input file as shown below.

```
2072 1114 1113 1160; 2073 1045 1160 1113;

Go to the Geometry | Parametric Models page and the saved parametric mesh models will appear within the Parametric Models dialog box as shown in the next figure.
There are two parametric mesh models named `second_floor` and `roof` inside the **Parametric Models** dialog box as shown in the previous figure.

**Note:** Please refer to the example file `parametric_models.std`, which is available under various country folders.

**Related Links**
- **Parametric Models dialog** (on page 2910)

**AD.2006.1.4 Persistency of Parameters User to Generate ASCE Wind Load in STAAD Input File**

In the past, once the wind load as per the ASCE-7 code was generated automatically using the wind load generator, no information about the parameters was retained by STAAD. So, there was no way to check the parameters, based on which the generation was done. Moreover, if any modification was required at a later stage, all the parameters had to be defined afresh. Automatic wind load generation feature has now been enhanced and the parameters can now be saved as part of the STAAD.Pro model.

Special tag based commands has now been introduced to support saving of ASCE parameters as part of the STAAD input file as shown below.

```
DEFINE WIND LOAD
  TYPE 1
  INT 0.017517 0.017517 0.0176388 0.017754 0.0178632 -0.0179672 0.0180665 0.0181615
  0.0182526 0.0183402 0.018506 -0.0184246 0.0185846 0.0186607 0.0187345 -
  26.5385 27.6923 28.8462 30

<! STAAD PRO GENERATED DATA DO NOT MODIFY !!!
ASCE-7-2002:PARAMS 85.000 MPH 0 2 2 0 0.000 FT 0.000 FT -0.000 FT 1 1 30.000 FT
```
When a user goes back to the Load page and goes to Definitions | Wind Definitions page and double clicks on the Intensity as shown in the next figure,

the intensity versus height data shows up as shown below.

One can now click on the Calculate as per ASCE-7 button and the parameters that were initially defined are going to appear in the resulting dialog boxes.

Note: Please refer to the example file ASCE_WIND_load_generation.std, which is available under various country folders.

- TR.31.3 Definition of Wind Load (on page 2623)
- ASCE 7 Wind Load dialog box (on page 3039)
- Wind Load tab (on page 3018)
- M. To add an ASCE 7 wind load definition (on page 836)

AD.2006.1.5 Enhancement of Z UP System

Earlier, when geometry created using a CAD software that used Z axis as the vertical axis, had to be imported into STAAD.Pro, the users had to reorient the model to make the Y axis the vertical axis before getting the model into STAAD.Pro. This was necessary because a number of STAAD.Pro load generation commands did not work.
when the Z axis was defined as the vertical axis. In STAAD.Pro 2006 these limitations has been addressed. All the load generations are going to work with the Z axis up coordinate system.

The default coordinate system for a model can be set by going to File > Configure. The Configure option is only available when no STAAD model is open. If a STAAD model is open, one has to click on File > Close to close the file first.

The Configure Program dialog comes up as shown in the next figure.

The Z up option can then be selected and applied to the model. This would set the Z axis to be the vertical axis instead of the default Y axis. Subsequently all modeling, analysis and postprocessing items would be based on this coordinate system.

Related Links

• GS. To use Z as the vertical axis (on page 46)

AD.2006.1.6 Specification of Member Orientation Using Reference Vector

This feature will allow users to orient members by specifying a direction vector. Beta angles will be calculated by the software by itself based on the direction vector specification. The new reference vector will be defined with respect to the local coordinates of the member. This is going to make the task of orienting members much easier.

To access the feature go to Commands > Geometric Constants > Member Reference Point.

The Reference Point dialog box comes up where the vector for the reference axis can be specified as shown in the following figure. The local Y axis for the member is going to oriented along the vector. This X, Y, Z values are going to be based on the local axis system of the member.
The feature is explained in the next section with an example. Let us consider the beam shown in the next figure. The requirement is to rotate the cross section about the axis of the member in the direction as shown, such that the angle of rotation is governed by a slope of 1 horizontal to 2 vertical.

1. Select Commands > Geometric Constants > Member Reference Point. The Reference Point dialog opens.
2. Select the Vector option and specify the reference vector so that it is oriented as per the required slope.
3. Click OK. The member is rotated to the reference vector.
The member gets oriented correctly without the user having to take the trouble of calculating the beta angle. In the STAAD input file, the following command lines get written.

```
CONSTANTS
  REFSVCTOR 0 2 1 ALL
```

Beta angle for the member can be easily figured out by simply double clicking on the member that brings up the **Beam** dialog box as shown next. The correct beta angle of 26.5651 is automatically calculated by STAAD.Pro based on the reference vector specification.

![Beam dialog box](image)

**Related Links**

- **TR.26.2 Specifying Constants for Members and Elements** (on page 2503)
- **M. To align a member to a reference point** (on page 796)

**AD.2006.1.7 Single File Archive to Save All STAAD Input & Output Files**

Based on user configurations, file open and save dialogs will allow user to select .stz (std archive) files. The archive will be expanded to TEMP folder or user configurable working folder. All input/output will be created at that location.
While exiting the program/session, all of those files will be archived again under same name and copied to original source folder.

Archive related commands can be found on the File menu.

**AD.2006.1.8 Auto Calculation of Effective Length Factors of Members as per AISC Code**

STAAD.Pro has a new feature to auto-calculate the Effective Length Factors (KY, KZ etc), for the members to be designed as per AISC-ASD Code.

To make use of this feature, the user needs to go to the Design | Steel page. Select the Country Code as AISC ASD. Select the member for which the Effective Length Factors are to be calculated. Click on the Define Parameters button and select the parameter KY or KZ.

The following dialog box will appear.
The only difference from the previous version of STAAD.Pro is the addition of the Calculate button as marked in the figure.

On clicking the Calculate button, the program will ask whether the braced or un-braced effective length of the selected member is required.

After getting confirmation from the user, the program will calculate and display the value of the Effective Length Factor in the Edit box.

Now, click on the Assign button to associate this value of the respective Effective Length Factor with the selected member.

Note: The calculation of the effective length factors are done as per a paper titled Compression Members presented by George Tsiatas.

AD.2006.2 Features affecting the Post-Processor (Results Mode)

Several new features have been added and existing features have been modified in the post-processor section of the program. They are explained in the following pages.

AD.2006.2.1 Generation of Transfer Force Report for Connection Design

STAAD.Pro can now calculate the “Transfer force” or “pass through force” that can be used for connection design. This feature is based on a paper on the subject by Dr. William A. Thornton. Refer to the next figure which shows beams and bracing members connected to either side of the column.
Transfer force is simply the maximum net horizontal force that gets transferred from the one side of the column to the other through the connection. So STAAD.Pro checks the forces in the members framing into each side of the column and finds out the resultant horizontal force for either side. Typically the resultant forces on the two sides would not be equal as some amount of force will be taken up by the column in shear. The greater of the two resultants is reported by STAAD.Pro as the transfer force. The option to determine transfer force automatically, will save engineers considerable time and effort as in most cases, they have to report the transfer forces in the design drawings. The same concept can be applied to floor bracing in horizontal plane.

**Description**

Go to the Post processing mode by selecting **Mode | Postprocessing** or by clicking on the **Postprocessing** tab above the graphics window. Select all the members that frame into any connection as shown in the previous figure. Then select **Report > Column Transfer**.

A dialog box titled **Transfer Force for Selected Members** comes up as shown in the next figure. The **Loads** box displays the load cases that has been considered to calculate the transfer force. By default all load cases are considered but one can exclude a few of them by simply clicking on the load case within the **Loads** box. The boxes **Left Beams** and **Right Beams** list all the members on the respective sides of the column along with their incidences. The boxes **Left TF** and **Right TF** shows the resultant horizontal force from either side. **Max TF** reports the transfer force.
Click on the Insert to Table button and a table will be generated containing all the transfer force information as shown in the next figure.

The transfer force information can also be included as part of a report by selecting File > Report Setup or by selecting the Report Setup tool, which will open the Report Setup dialog box as shown in the next figure.
By default, the **Transfer Force Report** appears in the selected list of items within the dialog box. A report with the transfer force data can then be generated as shown next.

![Transfer Force Report](image)

**Note:** Please refer to the example file `TransferForces.std`, which is available under various country folders.

**AD.2006.2.2 Customizable Color to Display Unity / Check Utilization Ratio**

View steel design results.

Default color for display of passed members was black. It has now been changed to green. The colors representing the various ranges for utilization ratios can be set by the user.
AD.2006.2.3 Enhancement to Steel Designer BS 5950 Calculation Sheets

The design calculation sheets of a steel section that has been designed with a BS 5950-1:2000 design brief has been modified with the following enhancements.

1. The terminology for elastic and plastic sections updated to use same terminology as in the design code.
2. A summary has been added at the end of the calculation sheet.
3. The section classification summary has been improved.
4. The reported dimensions of the section in the 'Compression Flange Buckling Check' have been improved.
5. The status for various checks has been re-titled.
6. Details of check to 4.8.3.3.1 added when required.
7. There are improved details of the clauses 4.8.2., 4.8.3. and Annex I1 calculations.
8. The 4.3.6. Lateral Torsional Buckling Check has been enhanced.
9. Additional detailed calculations for axially loaded members have been added to the document.
10. A number of spelling issues have been addressed.

AD.2006.3 Features affecting Analysis and Design

Several new features have been added and existing features have been modified in the analysis and design section of the program. They are explained in the following pages.

AD.2006.3.1 Pushover Analysis

This is a set of procedures to implement a Pushover Analysis as defined in the document FEMA 356:2000.

STAAD Pushover analysis in STAAD is a static, non-linear procedure in accordance with FEMA 356 specification. Basically, in this method, the magnitude of the lateral push load is increased progressively according to a predefined loading pattern until either loading or the deflection reaches the described level.

Please refer to M. Pushover Loads (on page 861) for details on using this feature.
AD.2006.3.2 Steady State Analysis

Please refer to Section 5.37.6 of the STAAD Technical Reference manual (on page 2807) for details.

AD.2006.4 Features affecting the RC Designer Mode

Several new features have been added and existing features have been modified in the RC Designer mode of the program. They are explained in the following pages.

Refer to the RC Designer Manual for full details. Note that references made here are for sections in the RC Designer Manual.

AD.2006.4.1 Slab Design to BS 8110

This a complete new mode that allows slabs to be defined from a collection of finite elements created from user defined meshes or surface objects. This release has added the design of slabs to BS8110.

AD.2006.4.2 BAEL Beam Design Enhancement

The BAEL 91 design code has been updated so that the limitation of reinforcement defined in clause A.8.1.21 is applied to the entire cross section, not just the compression zone of the cross section. This therefore allows for a greater amount of reinforcement in any given section. This new interpretation of the code is more in line with the code requirements in the EC2 and DIN codes.

AD.2006.4.5 Use of Generated Load Cases

The RC Designer has been enhanced to make use of the results of loadcases created by STAAD.Pro’s LOAD GENERATION command. These loadcases are now available for use in the Envelope definition, used by beam and slab design briefs and in the loadcases available for column briefs.

AD.2006.4.6 Use of Primary Load Cases in Column Designs

The RC Designer has been enhanced such that all column briefs can include the results of primary loadcases as well as combination loadcases.

AD.2006.4.7 BS8110 Beams Torsion Check Added

The BS 8110 beam design brief has been enhanced with the additional option of identifying the additional reinforcement required for the torsional forces. The additional reinforcement requirement is displayed in the Detail Design option of a user report.

See also

Engineering Information, 3.4.4.1. BS8110 Beam Design Principles

AD.2006.5 Additional STAAD.Pro 2006 Features

The additional enhancements made to STAAD.Pro 2006 are explained in the following pages.

AD.2006.5.1 STAAD.Pro Language Application

Recent changes to the program’s language facilities have deprecated these changes.

AD.2006.5.2 Section Wizard databases

Section Wizard Section Builder module and FreeSketch modules make use of defined standard steel databases. 3 new additional databases have been added and 3 have been updated.

New Additional Databases

- INDIAN.PRF - Indian
- JAPANESE.PRF - Japanese
SAFRICA.PRF - South African

Updated Databases

    BRITISH1.PRF – UK Corus
    DIN.PRF - German
    USA.PRF - ASTM

Note, all other databases are unchanged.

AD.2006.6 Features Added in STAAD.Pro 2005 Previously Undocumented

The following pages explain features that have been introduced into STAAD.Pro but were not fully documented in previous Release Reports.

AD.2006.5.1 DESCON, Advanced Connection Design Mode

Recent changes to the program's language facilities have depreciated these changes.

RAM Connection is now the supported facility for steel connection design in STAAD.Pro.

AD.2006.5.2 ADAPT Slab Design Mode

Recent changes to the program's language facilities have depreciated these changes.

Refer to the User Interface help for use with the Advanced Slab Design mode (on page 1353).

Note: Beginning with STAAD.Pro CONNECT Edition, direct export to ADAPT-Builder® has been deprecated.

AD.2006.6.3 BS5950 Part 5 - Cold Formed Steel Design

Refer to D3.E. British Codes - Design per British Cold Formed Steel Code (on page 1682) for details.

AD.2006.6.4 EC4 Timber Design

Refer to D5.E. European Codes - Timber Design Per EC 5: Part 1-1 (on page 1856) for details.

AD.2006.6.5 Canadian Timber Design

Refer to D4.D. Canadian Codes - Timber Design per CAN/CSA-086-01 (on page 1720) for details.

AD.2006.6.6 South African Steel Design

AD.2006.6.8 EC8 Earthquake Loading
Refer to TR.32.10.1.4 Response Spectrum Specification per Eurocode 8 1994 (on page 2710) for details.

AD.2006.6.9 Additional Kingspan Cold Formed Steel Database
Refer to TR.20 Member Property Specification (on page 2459) for details.

AD.2006.6.10 Imperfection Analysis
Refer to TR.26.6 Member Imperfection Information (on page 2511) for details.

AD.2006.6.11 Tapered Steel Design Added to BS 5950
Refer to D3.B. British Codes - Steel Design per BS5950:2000 (on page 1655) for details.

AD.2006.6.12 User Tools
The users can utilize their own customized tools, in form of VBS Macro, to operate on STAAD.Pro models.

The procedure of associating a user tool in STAAD.Pro is furnished below:

1. Run STAAD.Pro and Open an input file.
2. Select Tools > Configure User Tools.
   The Customize User Defined Tools dialog opens.

3. In the Menu-Items, add a name of the Tool, and in the Command, locate the Tool (VBS Macro) using the browser. Click OK to confirm.
4. Now the Tool name will appear in Tools > User Tools and also by selecting the Tools tool.
5. To Run the Tool (Macro), click on the Tool name in any of the places as described in step 4.

STAAD.Pro 2005 Release Report

This Software Release Report for STAAD.Pro Version 2005 contains detailed information on the additions and enhancements made to the program since the final build of STAAD.Pro 2004.

AD.2005.1 Features affecting the Pre-Processor

Several new features have been added and existing features have been modified in the pre-processor section of the program. They are explained in the following pages.

AD.2005.1.1 Generation of Wind Pressure profile per ASCE 7-02

STAAD.Pro is now capable of generating the wind pressure profile for a structure in accordance with the ASCE-7-02 code. The pressure profile is the table of values of wind intensity versus height above ground.

The calculated pressure may then be applied on the structure to compute loads on members using the program’s built-in wind load generation algorithm for the closed as well as open-lattice type structures.

Description

The steps required to generate the wind pressure profile are as follows:

In the General | Load page (from the vertical tabs on the left-hand side), go to the Load dialog box on the right and select Wind Definitions as shown in the next figure.

Click on the Add button to instantiate the Add New Wind Definitions dialog box shown in the next figure. Enter the Type No., which denotes a number by which the wind load type will be identified. Multiple wind types can be created in the same model. Click on the Add button within this dialog box and then click on Close.
The newly created TYPE 1 wind definition will appear underneath Wind Definitions in the Load dialog box as shown below.

Select the TYPE 1 name in the tree control and click on the Add button. The dialog box shown below will prompt for the pressure profile (intensity) for this wind definition.
As we said earlier, the pressure profile is the table of wind intensity versus height above ground. If we know that, that information can be typed into the box above. But, our goal is to calculate that. Hence, we click on the button Calculate as per ASCE-7.

The ASCE-7: Wind Load dialog box shown below will appear.

The options shown in the dialog box are explained below:

**Common Data**

Depending on which version of the code to use, choose either 1995 or 2002.
<table>
<thead>
<tr>
<th><strong>Building classification category</strong></th>
<th>Building classification category as obtained from Table 1-1 in SEI/ASCE 7-02. Category can be I, II, III or IV.</th>

<td>Specify the distance upwind of crest to where the difference in general elevation is half the height of the hill or escarpment (L&lt;sub&gt;H&lt;/sub&gt; in Figure 6-4 of the SEI/ASCE-7-02 code).</td>
</tr>
<tr>
<td><strong>Distance from the crest to the building (x)</strong></td>
<td>Specify the distance from the crest to the building site. A negative value signifies that the distance is in the downwind direction (X in Figure 6-4 of the SEI/ASCE-7-02 code).</td>
</tr>
</tbody>
</table>
Main Building Data

- **Building Height**: The height above ground to the highest point on the roof surface.
- **Building Length along the direction of Wind (L)**: Length of building measured along the direction of wind.
- **Building Length Normal to the direction of Wind (B)**: Length of building measured normal to the direction of wind.
- **Building Natural Frequency**: Specify the natural frequency of the building to calculate Gust Effect Factor.
- **Building Damping Ratio**: Specify the damping ratio to calculate Gust Effect Factor.
- **Enclosure Classification**: Classify the building as open building, partially enclosed or enclosed as per the provisions of section 6.2 of SEI/ASCE-7-02.
- **Kz**: Velocity pressure exposure coefficient that is calculated by STAAD.Pro as per Table 6-3 of the SEI/ASCE-7-02 code.
- **Kzt**: When wind speedup is considered, Kzt is calculated as per Eq 6-4 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and providing the required value in the edit box for Kzt.
- **I**: Importance Factor I is considered as per section 6.2 of the SEI/ASCE-7-02 code. Users can enter their own value by checking the Use box and typing the required value in the edit box for I.
### What's New?

STAAD.Pro 2005 Release Report

**Kd**

Wind directionality factor is calculated as per Table 6-4 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and typing the required value in the edit box for Kd.

The list of parameters explained earlier corresponds to the structure type called “Building Structures”. When structure type is varied, some of those parameters change. Those parameters that are different are explained below for each type of structure.

#### Structure type: Chimney, Tank, and similar Structures

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Height (H)</strong></td>
<td>Height of the structure as defined by the term ‘h’ in Figure 6-19 of the SEI/ASCE 7-02 code.</td>
</tr>
<tr>
<td><strong>Least Horizontal Dimension (W)</strong></td>
<td>Smaller of the plan dimensions. In case the cross section of the structure in plan is circular, the diameter needs to be specified.</td>
</tr>
<tr>
<td><strong>Horizontal Cross-Section Type</strong></td>
<td>This is the cross section of the structure in plan as defined in Figure 6-19 of the SEI/ASCE 7-02 code. The available options include square with wind being normal to face or acting along the diagonal, hexagonal, octagonal and round.</td>
</tr>
<tr>
<td><strong>Depth of protruding elements such as ribs and spoilers (D’)</strong></td>
<td>For round type cross sections, depth of protruding elements need to be defined which is a measure of the surface roughness as indicated in Figure 6-19 of the SEI/ASCE 7-02 code.</td>
</tr>
<tr>
<td><strong>C_f</strong></td>
<td>Force coefficient that is calculated by STAAD.Pro as per Figure 6-19 of the SEI/ASCE 7-02 code. The parameter is used for calculation of design pressure. If desired, users can enter their own value for C_f by checking the Use box and typing the required value in the appropriate edit box.</td>
</tr>
</tbody>
</table>

#### Structure type: Solid Signs

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Height (H)</strong></td>
<td>Height of the structure which is used for calculating the height to width ratio as defined by the term ‘n’ in Figure 6-20 of the SEI/ASCE 7-02 code.</td>
</tr>
<tr>
<td><strong>Horizontal Dimension of Sign (M)</strong></td>
<td>Horizontal dimension of the solid sign</td>
</tr>
<tr>
<td><strong>Vertical Dimension of Sign (N)</strong></td>
<td>Vertical dimension of the solid sign. If the sign is at the ground level, the height (H) and vertical dimension (N) should both be specified the same value.</td>
</tr>
<tr>
<td><strong>C_f</strong></td>
<td>Force coefficient that is calculated by STAAD.Pro as per Figure 6-20 of the SEI/ASCE 7-02 code. The parameter is used for calculation of design pressure. If desired, users can enter their own value for C_f by checking the Use box and typing the required value in the appropriate edit box.</td>
</tr>
</tbody>
</table>

#### Structure type: Open Signs / Lattice Frame Work

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Ratio of Solid Area to Gross Area</strong></td>
<td>Ratio of solid area to gross area as indicated by the term e in Figure 6-21 of the SEI/ASCE 7-02 code.</td>
</tr>
<tr>
<td><strong>Orientation of the members exposed to wind</strong></td>
<td>The type of member surfaces which are exposed to wind. Select flat-sided members or rounded members in Figure 6-21 of the SEI/ASCE 7-02 code.</td>
</tr>
<tr>
<td><strong>Diameter of typical round member</strong></td>
<td>Diameter for round members as defined by the term ‘D’ in Figure 6-21 of the SEI/ASCE 7-02 code.</td>
</tr>
</tbody>
</table>
Structure type: Trussed Tower

**Horizontal Cross Section**  The type of cross section of the tower in plan as defined in Figure 6-22 of the SEI/ASCE 7-02 code. The available options include square and triangle.

### Building Design Pressure

![Diagram of Building Design Pressure](image)

**Building Wall to generate Wind Load on:**

- **Windward** To generate the design wind pressure for the windward side, choose this option. The pressure will be calculated as per Equation 6-23 of the SEI/ASCE-7-02 code. The relevant equation is also displayed in the box just beneath the radio buttons.

- **Leeward** To generate the design wind pressure for the leeward side, choose this option. The pressure will be calculated as per Equation 6-23 of the SEI/ASCE-7-02 code. The relevant equation will be displayed in the box just beneath the radio buttons.

- **Side Wall** To generate the design wind pressure for the side wall, choose this option. As before, the pressure will be calculated as per Equation 6-23 of the SEI/ASCE-7-02 code. The relevant equation will be displayed in the box just beneath the radio buttons.

- **G** Gust effect factor calculated as per section 6.5.8 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and typing the required value in the edit box for G.

- **Cp** External pressure coefficient. The product of external pressure coefficient & gust effect factor is considered as per Figures 6-11 through 6-17 of the SEI/ASCE-7-02 code. Users can modify the value of Cp by checking the Use box and typing the required value in the edit box for Cp.

- **GCpi** Internal pressure Coefficients as per Figure 6-5 of the SEI/ASCE-7-02 code. Users can modify the value by checking the Use box and typing the required value in the edit box for GCpi.
The table on the right displays the intensities at various heights. Click on OK to arrive at the dialog box shown below.

Click on **Add** to add the load definition.

The defined wind loading can then be applied to the structure following the same procedure as in prior versions of the program. For details on the command syntax for generation of wind loads, refer to section 5.32.12: Generation of Loads from the STAAD Technical Reference Manual and example problem 15 in the Examples manual.

**Note:** The option we encountered earlier regarding the windward side, leeward side and side walls tells us that the pressure profile for each of those has to be individually determined under a unique type number. Thus, generating the profile for the 3 sides of the building constitutes 3 separate steps and thus, 3 separate types. Each type can then be applied with one load case or separate load cases and then applied in the relevant direction with the appropriate direction factor. Examples illustrating wind load generation can be found in the examples manual.

- **M. To add an ASCE 7 wind load definition** on page 836

**AD.2005.1.2 Generation of Snow Load Per SEI-ASCE 7-02**

STAAD.Pro is now capable of generating snow loading on a structure in accordance with the provisions of the ASCE-7-02 code. The feature is currently implemented for structures with flat or sloping roofs. Snow load generation for members of open lattice structures like electrical transmission towers is currently not part of this facility. Hence, the feature is based on panel areas, not the exposed width of individual members.

There are two parts to the command specification for snow load generation.
Part I

In this step, we define the parameters. In the General | Load page (from the vertical tabs on the left-hand side), go to the Load dialog box on the right and select Snow Definition as shown in the next figure.

Click on the Add button to instantiate the Add New: Snow Definition dialog box shown below. The Type No. is an integer value (1, 2, 3, etc.) which denotes a number by which the snow load type will be identified. Multiple snow load types can be created in the same model.

The fields in the above dialog box are:
**Ground Snow Load**  The pressure or, weight per unit area, to be used for the calculation of the design snow load. Use a negative value to indicate loading acting towards the roof (upwards) as per section 7.2 of SEI/ASCE 7-02.

**Exposure Factor**  Exposure factor as per Table 7-2 of the SEI/ASCE-7-02 code. It is dependent upon the type of exposure of the roof (fully exposed/partially exposed/sheltered) and the terrain category, as defined in section 6.5.6 of the code.

**Thermal Factor**  Thermal factor as per Table 7-3 of the SEI/ASCE-7-02 code. It is dependent upon the thermal condition.

**Importance Factor**  Importance factor as per Table 7-4 of the SEI/ASCE-7-02 code. This value depends on the category the structure belongs to, as per section 1.5 and Table 1-1 of the code.

Click on the Add button within the dialog box and then click on Close.

The newly created data will appear underneath Snow Definition in the Load dialog box as shown below.

The members for which the snow load has to be generated have to be clustered together into FLOOR GROUPs. That is because, as we saw at the beginning of this section, the load generation is based on panel areas, not the exposed width of individual members. For details on creation of groups, refer to section 5.16 of the STAAD.Pro Technical Reference manual, and AD.2004.11 of the Software Release report for STAAD.Pro 2004.

**Part II**

Create a new primary load case. After the load case number and load title have been specified, click on Add.

Select it in the Load dialog box and click on the Add button to bring up the Add New: Load Items dialog box as shown below.
Select **Snow load** from the available list of load types. Various options corresponding to data required for snow load generation will appear on the right hand side, as shown in the figure above. The options are explained as follows:

**Floor Group**  
Select the floor group on which the snow load is to be applied.

**Condition**  
Specify whether the load is "" or "Unbalanced". These terms are described in section 7.6, and figures 7.3 and 7.5 of ASCE 7-02.

**Define Snow Type**  
Select the snow load type number. This is the number specified against the **Type No.** field while creating the snow load definition in Part I described earlier in this section.

**Roof Type**  
Specify the roof type from the available choices:

- Default (if the roof type is not Mono, Hipped or Gable, it is referred to as Default)
- Mono (see mono-sloped roof shown in figure 6-6 of the code)
- Hipped (see figures 6-3 and 6-6 of the code)
- Gable (see figures 6-3 and 6-6 of the code)

These choices are described in section ... of ASCE 7-02.

**Roof Obstruction**  
Specify whether the roof is "obstructed" or "unobstructed". This also is a term described in section ... of ASCE 7-02.

**Roof Slope Factor**  
For sloped roofs, the roof slope factor is described in section 7.4 of the SEI/ASCE-7-02. A value of 0 indicates that the roof is horizontal.

Click on **Add** to complete the data input for Part II. The snow load command will appear underneath the snow load case in the **Load** dialog box as shown below.

AD.2005.1.3 Wall-slab Interface Considerations in Finite Element Meshing

In the plate element mesh generation for a panel type of entity like a wall or slab, STAAD.Pro now provides a facility for the consideration of boundary conditions at the interface of the panel and any other panel on whose surface one of its edge lies.

To illustrate the problem that one faces if the facility did not exist, consider the wall and slab shown in the figure below:

The Parametric Models facility may be used to mesh the slab, and use the wall boundary as a density line, resulting in the following mesh for the slab.
If the wall is to be meshed subsequently, the nodes along its common boundary with the slab, as shown in the above figure, must automatically be “control points” in the wall meshing process. There was no simple way to do this until now.

**Related Links**
- *M. To define a slab/wall connection* (on page 660)

**AD.2005.1.4 Enhancements to Renumbering of Entities**

The capabilities of the program in renumbering entities such as joints, members, plates, etc. have been enhanced. In the past, only a limited amount of control was available in the manner in which renumbering was to be done. The current enhancements enable a user to set multiple criteria and assign them an order of priority.

**Description**

We will use example problem 14 in the US examples folder to illustrate this. We will renumber the columns of one frame of this multi-story building. If you do not wish to modify the file supplied with the program, you may make a copy of the file before you start this exercise.

After opening the model, go to Select > By Range > XY, and set the minimum and maximum Z coordinate values to -1 ft and 1 ft respectively.
The members at the rear of the structure will be highlighted. Select View > New View > Display the view in the active window > .

Switch on the beam numbers and we get the following.
Our goal is to renumber the columns in such a manner that we will have the following once the renumbering is complete.
To accomplish that, do the following:

Select **Select > Beams Parallel to > Y**. The columns will be highlighted. Select **Geometry > Renumber > Members**.
What's New?
STAAD.Pro 2005 Release Report

The following message will be displayed.

Choose Yes, and the Renumber dialog box will appear.

It is apparent from the earlier figure that if we set the renumbering criteria to be based on X coordinate first and Y coordinate next, the program will internally create the following sequence for renumbering:

301, 317, 333, 302, 318, 334, 303, 319, 335, 304, 320, 336

So, the settings for the dialog box should be as follows:

Start numbering from = 1001
Select Sort Criteria = X Coordinate (Ascending), Y Coordinate (Ascending)

Click on Accept.
A message indicating the successful completion of the operation will appear.

Subsequently, the following view will appear on the drawing.

In past versions, 4 separate renumbering operations, each involving one line of columns, would have been required to achieve the same thing.

It is also worth noting that if the user wishes to renumber all the columns of all the frames in sequence, the Z coordinate can be included as a third criteria for sorting.

**Notes**

1. The order of importance of the sort criteria can be changed by clicking on the Up and the Down arrow keys as shown below.
Use these keys to change the order of the sort criteria

2. For the individual criteria, if you wish to change the order from Ascending to Descending or vice versa, double click on the item in the list as shown. For example, if you want the extreme right columns to have a lower number than the extreme left, set the criteria for X coordinate to Descending.
   Double-click on the individual items to change the order from Ascending to Descending and vice-versa.

3. If you want the entity to be numbered in the descending order instead of ascending order (as in 99, 98, 97, 96, ..., etc.), choose the appropriate button shown in the next figure.
   Click here to set the numbering sequence to Ascending or Descending.

AD.2005.1.5 Property Calculator for User Table General Sections

The user table section type called General has been enhanced in the following manner:
a. The shape of the section can be defined in terms of coordinates of the corner points of its cross section outline.

b. A section property calculator built into that dialog box enables the values to be calculated instantaneously. Any values the user wishes to override can be changed by typing over them.

c. Points can be defined at which stresses are to be reported in the Beam-Stresses page of the post-processing mode.

Description

Select **Tools > Set Current Input Units**, and choose the length unit in which to specify the dimensions of the cross section. Let us choose inches for this exercise.

Next, select **Tools > Create User Table**. In the **Create User Provided Table** dialog box, click on **New Table**.

Select **General** for the **Select Section Type**. Click on **OK**.

The table number will appear as 1. Click on **Add New Property**. The following dialog box will appear.
Let us say that we would like to define a cross section as shown below.
Assuming the top left corner of the cross section to be (0,0) for (Y,Z), Z being along left-right and Y along top-bottom, specify the data as shown in the next figure. The sequence of steps is circled in the next figure. Once the points are specified, click on Compute Section Properties and observe the values being computed and filled in the relevant boxes (step 4 in the next diagram)

Steps
1. Select Define Profile Polygon
2. Type TWOLEGGEDTEE in the Section Name field.
3. Type the vertex coordinates in the table.
4. Click Compute Section Properties.

You will observe that when we clicked on Compute Section Properties, the Y and Z coordinates of the corner points that we typed earlier will be replaced by values that are measured from the center of gravity of the section.

If you wish to specify the locations on the cross section where stresses are desired, they must be provided too. Note that the coordinate locations for that box should be based not on the arbitrary datum point we started out with initially, but on the basis of the center of gravity of the section.
These are points where stress reports are desired in the **Beam | Stresses** page in the post-processing mode. The coordinates of these points are measured from the CG of the section and not from an arbitrary point.

Once the section is defined, it may be assigned from the General-Properties page in the conventional way. Some of those steps are shown in the next 2 figures.
For the case of the example above, the following command syntax will appear in the STAAD input file.

START USER TABLE
TABLE 1
UNIT INCHES KIP
GENERAL

AD.2005.1.6 Stretch Members

This new facility allows one to increase the length of a member in various ways. The benefit it offers is that a member may be extended even if one does not readily know the coordinates of its ends joints in its stretched condition, something a user may appreciate in the case of members whose axis lie at an inclination to the global planes.

Description
Select the member which is to be extended. In the Geometry menu at the top of the screen, the option called Stretch Selected Member(s) becomes active.
Click on it and the following dialog box will appear.

The various options of the dialog box are explained below.

Select member(s)  Multiple members can be selected simultaneously for stretching. However, whether they will get stretched or not depends upon the type of method used in stretching as described later. If you wish to remove one or more members from the list, uncheck the corresponding boxes.
Uncheck those members which you do not wish to stretch.

The methods available for stretching are:

**To a point**
Specify the coordinates in current length units of the point to which one of the ends of the member are to be moved. The point must lie on the axis of the member being stretched, or else, the stretching will not be performed. The program automatically determines which of the two ends of the member is to be moved. So, this method involves

i. determining if the point lies on the axis of the member(s) being stretched.
ii. determining which end to move for the member(s) which satisfy criteria (i)
iii. replacing the corresponding nodal coordinates with those of the desired point.

**Through a distance**
In this method, the user has to merely specify the distance by which the start or end node must be stretched.

Choose the end which should be stretched. Specify the distance by which to stretch.

In this method, all members selected for this operation will see the change in length. The next diagram illustrates this. If this causes member to cross each other, the user must create the intersection point using the Geometry – Intersect Selected Members tool as the program does not automatically create it in the Stretch operation.
To an existing node
This is very similar to the To a point method described earlier. The only difference is that instead of explicitly specifying the coordinates of the desired point, that point is already available for identification through its node number.

To an existing member
If 2 members are oriented in such a manner that the local X-axis of one of those members can potentially intersect a second member within the span of that member, this method may be used to stretch the first member to meet the second member. In the next figure, member 42 may be stretched so it meets member 73. The second member will be automatically split up at the intersection point into two segments.

The dialog box settings required to achieve this are as follows:
Notes

In the **To an existing node** method, a graphical tool is available for selecting the node from the drawing as shown in the next figure.

In the **To an existing member** method, a graphical tool is available for selecting the member from the drawing as shown in the next figure.

In the **To an existing node** method, use this tool graphically select an existing node from the model.

In the **To an existing member** method, use this tool graphically select an existing node from the model.

The **Details** button may be switched on to view the internal details of the stretch operation.
AD.2005.2 Features Affecting the Post-Processor

The additions and enhancements to the post-processor section of the program are explained in the following pages.

AD.2005.2.1 Floor Vibration Analysis

The adequacy of a floor system from the standpoint of its vibration serviceability due to human activity, specifically walking excitation, can now be assessed using STAAD.Pro. The procedures of Chapters 3 and 4 of the AISC Steel Design Guide Series No. 11 - Floor Vibrations due to Human Activity - have been implemented.

Tutorial Problem

A composite deck is system composed of a concrete slab lying over a steel deck with or without ribs. The steel deck in turn is supported by steel beams or joists and they span the distance between girders and are supported by those girders. The slab may or may not be connected to the joists by shear studs.

To model this system in STAAD, one has to go to Geometry > Composite Deck from the left side of the screen as shown in the next figure:
The **Composite Deck** dialog opens on the right side of the screen as shown in the next figure.
When you click on the **Create New Deck** tab, you will see the mouse cursor change to look like an icon of a colored composite deck. To define the periphery of the composite deck, click the corner nodes in clockwise or counter-clockwise sequence using this mouse cursor. The last click must be on the starting node to close the periphery. In the figure shown, the sequence used is A-B-C-D-A.

The name of the composite deck will appear in the **Composite Deck** dialog. Click on that name and then dialog box will display several additional contents as shown in the next figure.
In the main view, the composite deck will appear in hatched lines. An arrow mark will indicate the direction along which the composite deck spans. This arrow will appear by default. To change the span direction, select two beams whose X axis is perpendicular to the intended span direction, and click on the tab **Create Direction**.

Define the concrete properties, rib properties and connectivity details in the appropriate fields of the **Composite Deck** dialog. To save the properties, click on the tab **Update Deck Property** (see previous figure). A sample data set is shown in the next figure.

**Command in the STAAD Input File**

When the data is specified in the dialog boxes as we saw earlier, it is also simultaneously stored in the STAAD input file in the appropriate command syntax. For the data we specified previously, the corresponding editor input will be as follows:

```plaintext
START DECK DEFINITION
  _DECK FLOOR1
  PERIPHERY 1 TO 8
  DIRECTION -1.000000 0.000000 0.000000
  COMPOSITE 10 9 4 8
```
Floor Vibration Report

In order to obtain the report, the finished model must be successfully analyzed. Go to the post-processing mode. Select Report > Floor Vibration Report as shown in the next figure.

The **Floor Vibration Output** dialog as shown in the next figure will appear. Select the deck name, the load case, and click on Check to see the report.

1. Select the composite deck from the drop-down list.
2. Select the load case.
3. Click **Check**.
What's New?
STAAD.Pro 2005 Release Report

An output similar to the one shown below will appear.

The terms displayed in the above box have been explained earlier.

AD.2005.3 Features Affecting Analysis and Design

Some new features have been added and existing features have been modified in the analysis and design part of
the program. They are explained in the following pages.

AD.2005.3.1 Designing I-beams w Web Openings per AISC ASD

Design of steel members with web openings per AISC Steel Design Guide 2 - ASD specifications is now available
in STAAD. The facility is available for members whose yield strength is 65 ksi or less.

Note: In the current implementation, the web openings are given consideration only during the design phase.
The reduction in section properties caused by the presence of the openings is not considered automatically
during the analysis phase. Hence, the analysis is performed as if the full section properties are effective for such
members.

During the design process, the program first determines the utilization ratio (U.R.) at the location of the opening
as though it is an unreinforced opening. If the U.R. is less than 1.0, the member is presumed to have passed the
requirements at that location. If the U.R. exceeds 1.0, then it determines the U.R. as though it is a reinforced
opening. If it fails this too, the cause of the failure along with the associated numerical values is reported.
T.1 – Steel Portal Frame

This chapter provides a step-by-step tutorial for creating a 2D portal frame using STAAD.Pro.

![Portal Frame model](image)

**Figure 9: Portal Frame model**

**T.1 Methods of creating the model**

There are three methods of creating the structure data:

1. Using the STAAD.Pro Physical Modeler interface (on page 377),
2. Using the traditional STAAD.Pro analytical modeling interface (on page 385),
3. Using the command file (on page 428)

The physical model is used to draw structural elements as they are physically constructed. The program will then decompose this into an analytical modeling which is passed to the STAAD.Pro analysis and design engine when you run your model.

The analytical model is a finite element model of the structure which is typically processed directly by the analysis and design engine.
The command input file is a text file which contains the data for your structural model. This file consists of simple English language-like commands. This file is created for you behind the scenes when you model your structure using either the physical modeler interface or the analytical model interface.

The physical model will be linked to the command input file so any changes to your physical model must be made using the physical modeler interface. This ensures data integrity when the program decomposes the physical model. You can “break” this link to make changes to the underlying analytical model directly, either using the STAAD.Pro analytical modeling interface or using the command input file editor.

You can switch back and forth between the analytical modeling interface and the command input file editor for models created by either of those methods.

All three methods are described in this tutorial, with a detailed focus on the STAAD.Pro Physical Modeler interface.

**T.1 Description of the tutorial problem**

The structure for this project is a single bay, single story steel portal frame that will be analyzed and designed.

![Figure 10: Portal Frame model](image)

**Table 21: Basic Data for the Structure**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Member properties</td>
<td>Members 1 &amp; 3 : W12X35</td>
</tr>
<tr>
<td></td>
<td>Member 2 : W14X34</td>
</tr>
<tr>

<td>Modulus of Elasticity : 29,000 ksi</td>
</tr>
<tr>
<td></td>
<td>Poisson’s Ratio : 0.30</td>
</tr>
</tbody>
</table>
### Attribute | Data
--- | ---
Member Offsets | 6.0 inches along global X for member 2 at both ends
Supports | Node 1: Fixed  
Node 4: Pinned
Loads | Load case 1: Dead + Live  
Beam 2: 2.5 kips/ft downward along global Y  
Load case 2: Wind From Left  
10 kips point force at Node 2  
Load case 3: 75 Percent of (DL+LL+WL)  
Load Combination - L1 X 0.75 + L2 X 0.75
Analysis Type | Linear Elastic (PERFORM)
Steel Design | Consider load cases 1 and 3 only.  
Parameters: Unsupported length of compression flange for bending: 10 ft for members 2 and 3, 15 ft for member 1.  
Steel Yield Stress: 50 ksi  
Perform member selection for members 2 and 3

#### T.1 Creating a new structure

On the Start page **New** tab, you will provide some initial data necessary for building the model.

1. On the Start page, select **New**.

   The **New** page opens to the **Model Info** tab.

2. Type **PORTAL** in the **File Name** field.
3. Specify a **Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.

4. Select **Physical** for the **Type** of model.

   This option selects the modeling method you want to use:

   - **Analytical** For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.
   - **Physical** For creating a model using the STAAD.Pro Physical Modeler interface.
   - **Building** For creating a building model structure using the Building workflow.

5. Select **English** as the system of **Units**.

   **Tip:** The units can be changed later if necessary, at any stage of the model creation.

6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.

7. Click **Create**.

The STAAD.Pro modeling environment opens and your model file is then opened in the STAAD.Pro Physical Modeler.

Alternatively, if you want to use either the analytical modeling workflow or the command input file editor to create the model, choose **Analytical**, click **Create**, and then proceed to either "[T.1 Creating the model using the analytical user interface](#)" (on page 385) " or "[T.1 Creating the model using the command file](#)" (on page 428)," respectively.
T.1 Creating the Model using the Physical Modeler

You are now ready to start building the model geometry. The steps for doing this are described in the following sections.

**Tip**: Refer to the STAAD.Pro Physical Modeler Application Window Layout for reference on the application window.

### T.1 Generating the model geometry

1. On the **Model** ribbon tab, select the **Grid** tool in the **Create** group.

   ![Create Grid dialog](image)

   The **Create Grid** dialog opens.

2. Supply the grid details:
   a. Type **Grid 1** in the **Name** field.
   b. Leave the **Plane** selection as **XY** and the **Creation Method** as **By Spacing**.
   c. Type 20 in the **Number of spaces in X** and 1 ft in the **Grid spacing X** fields.
   d. Type 15 in the **Number of spaces in Y** and 1 ft in the **Grid spacing Y** fields.
   e. Click **OK**.

   The grid is created.

   You can control the visibility of individual grids by selecting the **Grids** tool on the **Spreadsheet** ribbon tab, where you can also change the settings for each grid. You can have as many grids as necessary displayed at one time.

3. On the **Model** ribbon tab, select the **Member** tool in the **Create** group.

   ![Member tool highlighted](image)

   The tool is highlighted to show it is active. A yellow circle highlights the grid intersection the cursor “snaps” to when you hover in the view area.

4. Click on the lower, right corner of the grid (i.e., the origin at 0,0,0).

   A dashed line is “rubber banded” from this point to your cursor.

5. Click on the following two points around the edge to draw two members:
   
   (0,15,0)
   (20,15,0)

6. Double-click on the final point at (20,0,0).

   This instructs the program you are finished drawing connected members.

   **Tip**: The tool remains active until so you can continue drawing a new set of connected members elsewhere if necessary.

7. Select the **Member** tool again to make it inactive.

8. On the **View** ribbon tab, select the **Grids** tool in the **Reference** group.
The tool is no longer highlighted and all grids are hidden in the display.

9. Switch on the node and beam labels:
   a. On the View ribbon tab, select the drop-down list below the Numbering tool in the Model group.

   - Select Node and Member on this list.
   - They are both marked with a check.
   - Select the Numbering tool.

You have now created the nodes and members for this model.

You can review the geometry of each by selecting the Nodes tool in the Nodes group and Members tool in the Members group on the Spreadsheet ribbon tab, respectively.

**T.1 Specifying member properties**

*Tip:* In STAAD.Pro Physical Modeler, you will select a model object and then assign properties, loads, etc. to that object. This fundamental workflow is import to understand as it applies to essentially all actions once you have drawn your model objects.

1. Select the two column members (M1 and M3):
   a. Click anywhere in the empty area in the view window.
      All model objects (members and nodes) are deselected.
   b. Click-and-drag a line horizontally from right to left across the columns to select them.
      This method (i.e., right to left) will select any model object that your drag window crosses.
Note: The Member ribbon tab reappears any time you have one or more members in your current selection.

2. On the Member ribbon tab, select the Section tool in the Assign properties group.

The Assign Section dialog opens.

3. Specify the section data for the columns:
   a. Leave all the defaults:
      - Type: Standard,
      - Country: United States,
      - Material: STEEL,
      - Category: Hot Rolled,
      - Specification: AISC,
      - Version: 14 Edition,
      - Manufacturer: Generic
   b. Select W from the Table drop-down list.
      The list of all section names in this table are populated.
   c. Scroll to and select W12X35 in the list.
   d. Click OK.
   The section is assigned to the columns.

4. Click on the beam member.
   It is selected and all other members are deselected.

5. Repeat steps 2 and 3 except to assign a W14X34 to the beam (M2).

6. Select all three members by either:
   - click-and-drag a window around them
   - press <Ctrl+A>
   - or
   - on the Data ribbon tab, select the Select all tool in the Model group

   Tip: There are numerous ways in which to select all the beams in a model. These are some examples.

7. On the Member ribbon tab, select the Material tool in the Assign properties group.

The Assign Material dialog opens.

8. Specify the material data for the members:
a. Leave the initial defaults:
   
   Source: Catalog
   Type: Standard
   Country: United States
b. Select ASTM_STEEL from the Specification drop-down list.
c. Select A992 from the Name list.
d. Click OK

The material is assigned to the members.

T.1 Specifying member offsets

1. Click the beam member (M2) to select it.
2. On the Member ribbon tab, select the End Offset tool in the Edit group.

   The Modify Member End Offsets dialog opens.
3. Specify the start (in this case, left) node offset:
   a. Leave the Direction as Local.

   Tip: Given the orientation of this beam, the local 1 and global X axis are parallel, but it's best practice to use local coordinates when the offset is taken with respect to the local member's ends.
   
   b. Type 6 in in the x direction.
   
   Local axis 1, 2, and 3 correspond to the member's localized X, Y, and Z axis.

   Tip: Notice that even though the default input units are in feet, you are able to type different units and the program converts to the input units for you.

4. Specify the end (in this case, right) node offset:
   a. Leave the Direction as Local.
   b. Type -6 in in the x direction.

   Note: The negative sign for the offset value at the end.

5. Click OK

The end offsets are drawn as red lines from the nodes in their indicated direction.

T.1 Specifying supports

1. Click on the lower-left node (N1) to select it.

   Any other selected items are removed from the current selection set. The node is selected. The node label appears if you have the labeling turned on.

2. On the Node ribbon tab, select the Fixed tool in the Supports group.

   A fixed nodal support type is assigned to this node.

3. Select the lower-right node (N4).
4. On the Node ribbon tab, select the Pinned tool in the Supports group.
A pinned nodal support type is assigned to this node.

**Tip:** You can use the Custom tool in the Supports group to generate any restraint or spring nodal boundary condition necessary.

You can review the nodal boundary conditions by selecting either the Supports tool or the Springs tool in the Nodes group on the Spreadsheet ribbon tab.

### T.1 Viewing the model in 3D

1. Select all model objects by either:
   - Right-click in the view area and select **Select All** from the pop-up menu
   - Click-and-drag a window area around all model objects
   - Press `<Ctrl+A>`
2. On the View ribbon tab, select the 3D Rending tool in the Model group.

   The tool is highlighted to indicate it is active. The view displays the rendered model using the member’s shapes, materials, and properties such as end offsets.

   You can continue to model and work with this view option turned on. However, it is typically clearer to work with line drawings. Select the 3D Rendering tool again to deactivate it.

### T.1 Specifying loads

The STAAD.Pro Physical Modeler creates a default Load Group 1 with the no specified load type. You will add the dead and live loads to this load group and then create a new load group for the wind load.

1. On the Spreadsheet ribbon tab, select the Load cases tool in the Reference group.

   The Load Cases spreadsheet opens.

2. For Load case 1, type Dead + Live in the Name cell to rename the load case.
3. Click the beam member (M2) to select it.
4. On the Member ribbon tab, select the Distributed tool in the Loads group.

The Add Member Distributed Load dialog opens.

5. Specify the load:
   - Leave the Load Group as LC: Dead + Live and the Load Type as Uniform.
   a. Select Global Y as the Direction.
   b. Type -2.5 kip/ft in the Magnitude field.
   c. Click OK.

   The load is applied to the beam.

6. On the Model ribbon tab, select the Load Case tool in the Loads group.

The Add Load Case dialog opens.

7. Specify the wind load case details:
   a. Type Wind From Left in the Name field.
   b. Select Wind for the Type.
   - Leave the other items for Self-weight data empty (default).
   c. Click OK.

   A new load case is added to the Load Cases spreadsheet and the load is automatically selected in the program window status bar as the current load.

   **Note:** When load items are created they are added to the current load case or load group by default.

8. Select the upper-left node (N2).
The **Add Nodal Load** dialog opens.

10. Specify the lateral wind load:
    a. Leave the **Load group** selection as **LC: Wind from left**.
    b. Type 10 kip in the **Fx** field.
    c. Click **OK**.

### T.1 Creating a load combination

1. On the **Model** ribbon tab, select the **Load Combination** tool in the **Loads** group.

   ![Image]

   The **Add Load Combination** dialog opens.

2. Type **75 Percent of [DL+LL+WL]** in the **Name** field.

3. Select **Linear** as the load combination **Type**.

4. Click in the **Load case filter** field and then check the **(Select All)** option.

5. Assign the load case factors:
    a. Click in the **Factors** field.
       The load case factors table opens. All the load cases in the model are included from the previous step.
    b. For load case 1 (the first row in the table), click in the **Factor** cell and type **0.75**.
    c. Repeat step 5a to enter a load case factor of 0.75 for the wind load (load case 2).
    d. Click **OK**.
6. Click OK.

T.1 Generate the analysis model

You have now completed the modeling portion of this tutorial. You will now send the model data back to STAAD.Pro where you will create load combinations, add output commands, select analysis criteria, and specify design parameters.

For this tutorial, you will use the default options for analytical model generation. However, for advanced models you can review and change those options in the Configuration dialog.

1. Select Save to save the physical model.
2. Either:
   - On the Model ribbon tab, select the Return to Analytical Modeling tool in the STAAD.Pro group
or

On the **File** ribbon tab, select **Create analysis model** in the backstage tabs.

The Return to Analytical Modeling dialog opens and displays the progress of the analytical model being generated.

3. Click **OK**.

If you have not previously associated this model with a CONNECT Project, you are asked to do so. This is will not be necessary for this tutorial.

4. Click **Cancel** in the **Assign Project** dialog.

The STAAD.Pro Physical Modeler window closes and the model is loaded into the STAAD.Pro analytical modeling interface.

**T.1 Creating the model using the analytical user interface**

The following procedures describe how to use the traditional STAAD.Pro analytical user interface to build the model. The steps and, wherever possible, the corresponding STAAD.Pro commands (the instructions which get written in the STAAD input file) are described in the following sections.

**Tip:** Refer to Application Window Layout (on page 50) for reference on the application window.

**Note:** If you completed the model using the **Physical Modeling** workflow, then instead proceed to T.1 Analysis and Design (on page 412).

**T.1 Generating the model geometry**

The structure geometry consists of joint numbers, their coordinates, member numbers, the member connectivity information, plate element numbers, etc.

The STAAD input file commands generated are:

```
JOINT COORDINATES
1 0. 0. ; 2 0. 15. ; 3 20. 15. ; 4 20. 0.
MEMBER INCIDENCE
1 1 2 ; 2 2 3 ; 3 3 4
```
When starting in the Analytical Modeling workflow, a grid is initially displayed in the main view window. This grid is controlled by the **Snap Node/Beam** dialog. The directions of the global axes (X, Y, Z) are represented in the icon in the lower left hand corner of the drawing area.

![Figure 11: The STAAD.Pro window with the Snap Node/Beam dialog open](image)

**Note:** The **Snap Node/Beam** dialog opens on the right side of the screen. You can reopen this dialog by selecting the **Snap Grid Beam** tool in the **Structure** group on the **Geometry** ribbon tab.

1. On the **Snap Node/Beam** dialog, click **Create**. A dialog opens which will enable us to set up a grid.

   Within this dialog, there is a drop-down list from which you can select Linear, Radial, or Irregular form of grid lines.

   - **Linear** used to place the construction lines perpendicular to one another along a "left to right - top to bottom" pattern, as in the lines of a chess board

   - **Radial** used to place construction lines to appear in a spider-web style, which makes it easy to create circular type models where members are modeled as piece-wise linear straight line segments

   - **Irregular** used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane

2. Select **Linear**, which is the **Default Grid**. In this structure, the segment consisting of members 1 to 3, and nodes 1 to 4, happens to lie in the X-Y plane. Leave X-Y as the **Plane** of the grid. The size of the model that can be drawn at any time is controlled by the number of **Construction Lines** to the left and right of the origin of axes, and the **Spacing** between adjacent construction lines.

3. Type a **Name of Grid 1**.

4. Type 20 as the number of lines to the **Right** of the origin along X and 15 above the origin along Y
Leave the default spacing of 1 feet between lines along both X and Y.

![Figure 12:](image)

5. Click **OK**.

6. In the **Snap Node/Beam** grids list, check the new **Grid 1** option.

   You can create any number of grids. By providing a name, each new grid can be identified for future reference.

   **Tip:** Please note that these settings are only used to generated construction lines. These construction lines enable you to easily draw the structure but do not restrict our overall model to those limits.

   **Tip:** To change the settings of this grid, select the name in the **Snap Node/Beam** dialog and then click **Edit**.

The check by **Default Grid** is automatically cleared. STAAD.Pro will only display a single grid at a time.
7. In the View window, click at the origin (0, 0) to create the first node.

   A line is "rubber-banded" between this node and the mouse pointer, which previews the member to placed with the next mouse click.

   The **Snap Node/Beam** feature is active by default.
8. Click on the following points to create nodes and automatically join successive nodes by beam members.

(0, 15)  
(20, 15)  
(20, 0)  

When steps 1 through 5 are completed, the structure will be displayed in the drawing area as shown below.

Figure 14:
9. Click **Close** in the **Snap Node/Beam** dialog. The grid is hidden.

![Figure 15: The portal frame members drawn](image)

It is important to save your work often. This helps to avoid loss of data and protect your investment of time and effort against power interruptions, system problems, or other unforeseen events.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL + S>`.

### T.1 Switching on node and beam labels

Node and beam labels are a way of identifying the entities in the View window.

1. Right click anywhere in the view window and select **Labels** from the pop-up menu.
   - The **Diagrams** dialog opens to the **Labels** tab.
2. Set the **Node Numbers** and **Beam Numbers** on and then click **OK**.
Figure 16: Select the Node and Beam numbers

**Tip:** Alternatively, you can press `<Shift+N>` and then `<Shift+B>` to quickly toggle the same labels. The letters in parenthesis on the *Labels* tab indicate these `<Shift>` key shortcuts.

**Tip:** You can change the font of the node/beam labels by selecting the File ribbon tab and then selecting **Settings > Display Options**. Select the appropriate tab (Node Labels / Beam labels) from the Options dialog.
T.1 Specifying member properties

In this procedure, you will assign cross section properties to the beams and columns. The STAAD input file commands generated are:

```
MEMBER PROPERTY AMERICAN
1 3 TABLE ST W12X35
2 TABLE ST W12X34
```

1. Select the **Properties** page in the Analytical Modeling page control bar.

   ![Properties - Whole Structure dialog](image)

   *Figure 17:*

2. Click **Section Database**.

   The **Section Profile Tables** dialog opens.
3. Select the **W Shape** tab under the **American** option.
   The property type we wish to create is the W shape from the AISC table.

4. Choose **W12X35** as the beam size and then select the **ST** option as the section type.
   **Tip:** The **Material** check box is set. Leave this set and the selection set to **Steel** as it will be used to assign the built-in steel material properties when this section is assigned.

5. Click **Add**.
   **Tip:** Detailed explanation of the terms such as ST, T, CM, TC, BC, etc. is available in Section 5 of the STAAD Technical Reference Manual.

The W12X35 section is added to the Sections list in the **Properties - Whole Structure** dialog.
6. To create the second member property (ST W14X34), select the **W14X34** shape and click **Add**.

7. Click **Close** in the **Section Profile Tables** dialog.

8. Assign these properties with selected members in our model:
   a. Select the first property reference in the **Properties** dialog (W12X35).
   b. Select the **Use Cursor to Assign** option in the Assignment Method group.
   c. Click **Assign**.
   
   The mouse pointer changes to 
   
   d. Click on members 1 and 3.
   e. To stop assigning properties, either:
      
      click **Assigning**
      
      or
      
      press the `<Esc>` key.

9. Repeat step 8 except to assign the second property reference (W14X34) to member 2.

After the properties are assigned to the respective members, the member labels will indicate the section reference numbers.

![Portal.std - Whole Structure](image)

*Figure 19:*

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL+S>`.

---

**T.1 Specifying material definition**

When selecting the steel sections (on page 392), you kept the **Material** option checked. Consequently, the material definitions were assigned to the members along with the sections.
The STAAD input file commands generated are:

```
DEFINE MATERIAL START
ISOTROPIC STEEL
E 4.176e+006
POISSON 0.3
DENSITY 0.489024
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 5184 FU 8352 RY 1.5 RT 1.2
END DEFINE MATERIAL
... 
CONSTANTS
MATERIAL STEEL ALL
```

T.1 Changing the input units of length

For specifying member offset values and for some material definition values, as a matter of convenience, use length units of inches instead of feet.

The STAAD input file commands generated are:

```
UNIT INCHES KIP
```

1. On the Geometry ribbon tab, select the Input Units tool in the Structure group.

The Set Input Units pop-up opens.

2. Select English as the Input Units.
3. Set the Length input units to Inch.
4. Click Apply.
T.1 Specifying member offsets

Member 2 (the beam) actually spans only the clear distance between the column faces rather than the center to center distance. This is modeled by specifying offsets.

Member 2 is offset at the start joint by 6 inches in the global X direction (and 0.0 and 0.0 in Y and Z directions). The same member is offset by negative 6.0 inches at its end joint.

The STAAD input file commands generated are:

```
MEMBER OFFSET
  2 START  6.0  0.0  0.0
  2 END    -6.0  0.0  0.0
```

1. Select member 2 by clicking on it in the view window.

   **Note:** If the beam cursor isn’t currently active, select the **Beam Cursor** tool in the **Selection** group on the **Geometry** ribbon tab.

   The selected member will be highlighted.

2. Select the **Specifications** page on the Analytical Modeling page bar. The **Specifications - Whole Structure** dialog opens. Member releases, offsets, and other beam specifications are defined here.

3. Click **Beam**.
The Member Specification dialog opens.

4. Specify the member start offset:
   a. Select the Offset tab.

   ![Member Specification dialog]

   b. Select Start as the Location.
   c. Type 6.0 (in.) in the X offset field.

   Leave the Direction as Global. It is convenient to define the offset at the start node in the X direction. Since the beam member is aligned with the global X axis, there is no difference between choosing a global or local frame of reference.

d. Click Assign.

The dialog closes and the offset specification is added to the start of member 2. This is displayed visually on the member as well as listed in the Specification list in the Specifications - Whole Structure dialog.

5. On the Specification ribbon tab, select the Beam > Offset tool in the Specifications group.

   ![Beam > Offset tool]

   The Member Specification dialog opens to the Offsets tab.

6. Specify the member end offset:
   a. Select End as the Location.
   b. Type -6.0 (in.) in the X offset field.
   c. Click Assign.

The dialog closes and the offset specification is added to the start of member 2.
Tip: Alternatively to steps 5 and 6, you can repeat steps 3 and 4, except for selecting the End option and providing a value of -6.0 for X. This procedure is used to demonstrate two methods to complete a similar task.

Figure 20: The model after both start and end offsets are assigned

Click anywhere in the drawing area to deselect the member.

Tip: Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL+S>.

T.1 Printing member information in the output file

It is useful to view the member information used by the program for analysis. You can add a report in the STAAD output file consisting of information about all the members including start and end joint numbers (incidences), member length, beta angle, and member end releases.

The STAAD input file commands generated are:

PRINT MEMBER INFORMATION ALL

1. Select all the beam members by one of the following methods:
   on the Select ribbon tab, select the All tool in the Beams group
   or
   click-and-drag a window around all members in the View window
   or
   press <Ctrl+A>

2. On the Analysis and Design ribbon tab, select the Pre-Analysis Commands tool in the Analysis Data group.
The Pre Analysis Print - Whole Structure dialog opens.
3. In the Pre Analysis Print - Whole Structure dialog, click Define Commands.
   The Analysis/Print Commands dialog opens.
4. Select the Member Information tab and then click Assign.

5. Click Close.

Click anywhere in the drawing area to deselect the member.

Tip: Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL +S>.

T.1 Specifying Supports

The boundary conditions of this problem call for restraining all degrees of freedom at node 1 (FIXED support) and a pinned type of restraint at node 4 (restrained against all translations, free for all rotations).

The STAAD input file commands generated are:

SUPPORTS
1 FIXED ; 4 PINNED
1. On the Select ribbon tab, select the Node Cursor tool in the Cursors group.

2. In the View window, click on nodes 1 to select it.

   Note: The Node Tools ribbon tab opens when nodes are selected.

3. On the Node Tools ribbon tab, select the Assign Supports tool in the Model dialog.

   The Supports - Whole Structure dialog opens.

4. In the Supports dialog, click Create.

   The Create Support dialog opens.
5. Select the **Fixed** tab (selected by default) and then click **Assign**.

   This creates a FIXED type of support at node 1 where all 6 degrees of freedom are restrained.

6. To create a PINNED support at node 4, repeat steps 2 through 5, except for selecting node 4 and selecting the **Pinned** tab in the Create Support dialog.
Figure 21: The portal frame with supports assigned

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL>+<S>`.

T.1 Viewing the model in 3D

You can review the model in 3D in the STAAD.Pro user interface.

Figure 22: The model rendered in three dimensions

1. Right-click in the view window and select **Structure Diagrams** from the pop-up menu.
The **Diagrams** dialog opens to the **Structure** tab.

The options under **3D Sections** control how the members are displayed.

- **None** displays the structure without displaying the cross-sectional properties of the members and elements.
- **Full Sections** displays the 3D cross-sections of members, depending on the member properties.
- **Sections Outline** displays only the outline of the cross-sections of members.

2. Select **Full Sections** and then click **OK**.
Tip: You can also change the color of the sections by clicking on the Section Outline color button in the Colors group.

Alternatively, you can quickly render the model in 3D in a new window either by:

- selecting the 3D Rendering tool in the Windows group on the View ribbon tab
- selecting View > 3D Rendering.

This method has no further settings for colors.

### T.1 Specifying Loads

Three load cases are to be created for this structure. Details of the individual cases are explained at the beginning of this tutorial.

The STAAD input file commands generated are:

```
UNIT FEET KIP
LOADING 1 DEAD + LIVE
MEMBER LOAD
  2 UNI GY -2.5
LOADING 2 WIND FROM LEFT
JOINT LOAD
  2 FX 10.
LOAD COMBINATION 3 75 PERCENT OF (DL+LL+WL)
  1 0.75 2 0.75
```

The creation and assignment of load cases involves the following steps:

1. Create the two basic load cases
2. Create a load combination as a third load case
3. Assign these loads to the respective members/nodes.

### T.1 Creating Load Cases 1 and 2

Load cases 1 and 2 are primary load cases. These load cases are used during analysis of the structure.

1. Change the length units to Feet by selecting the length unit in the application window status bar. See **T.1 Changing the input units of length** (on page 395).
2. On the Loading ribbon tab, select the Primary Load Case in the Loading Specifications group.

The Create New Primary Load Cases dialog opens.
3. Enter the properties for the first load case:
   a. Type DEAD + LIVE in the Title field.
      Leave the Number as the default value of 1.

      **Note:** The Loading Type list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program’s automatically generating load combinations in accordance with those codes. Note that there is a check box labeled Reducible per UBC/IBC. This feature is active only when the load case is assigned a Loading Type called Live when you create that load case.

      Since this tutorial does not use the automatic load combination generation feature, leave the Loading Type as None.

   b. Click Add.
      The load case appears under the Load Cases Details option in the Load & Definition dialog.

   c. Click Close.

4. On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.
The **Create New Load Items** dialog opens with entries for adding load items to the current load case.

5. Define the uniform load for this load case:
   a. In the **Create New Load Items** dialog, select the **Uniform Force** tab under the **Member Load** item.
   b. Select **GY** as the **Direction**.
   c. Type **-2.5** in the **W1** field (magnitude of the uniform force).
      - The negative value indicates the load acts "down".
      - Leave the offset fields (d1 through d3) as zero.
   d. Click **Add**.
   e. Click **Close**.

6. Repeat steps 2 and 3 to create the second load case, except title the load case as **WIND FROM LEFT**.
   - Again, leave the **Loading Type** as **None**.
7. Set the wind load case as the current load case:
   a. On the **Loading** ribbon tab, click the down arrow on the **Load** tool in the **Display** group. The **Select load** pop-up dialog opens.

   ![Load & Definition dialog](image)

   b. Select the **2: Wind From Left** primary load case. Load items created using the ribbon tab tools are added to the current load case.

8. On the **Loading** ribbon tab, select the **Load Items** in the **Loading Specifications** group.

   ![Create New Load Items](image)

   The **Create New Load Items** dialog opens with entries for adding load items to the selected load case.

9. Define the wind load at the joint:
   a. In the **Create New Load Items** dialog, select the **Node** tab under the **Nodal Load** item.
   b. Type 10 in the **Fx** field (magnitude of the force along the global X direction).
   c. Click **Add**.
   d. Click **Close**.
T.1 Assigning load cases to members

Load item assignments are made using the **Load & Definition** dialog, which opens when most of the Loading tools are selected. If this dialog is not currently open, select the Loading page in the Analytical Modeling page control bar to re-open it.

You may notice that the load items in the Load & Definition dialog are listed with an icon. This indicates that these load items are not yet assigned to any model objects (i.e., beams or nodes).

1. In the **Load & Definition** dialog, select the **UNI GY -2.5 kip/ft** load item in the **1: DEAD + LIVE** load case.

![Load & Definition dialog](image)

2. Select the **Use Cursor to Assign** option in the **Assignment Method** group.
3. Click **Assign**.

   The mouse pointer changes to 

4. Click on member 2.

   The uniform load is drawn on member 2 and the load item icon changes to \(\text{uniform load}^{*}\) in the **Load & Definition** dialog.

5. Repeat steps 1 through 4, except to assign the nodal load item in the second load case (FX 10 kip, ft) to Node 2.

*Figure 23: Uniform load item assigned to member 2*
6. To stop assignment load items:
   
   click **Assigning**
   
   or
   
   Press the <Esc> key.

What about the load combinations? These do not need to be assigned to any model objects. As you may recall, these represent a factored combination of the *results* of the primary load cases and thus are not directly analyzed.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing <CTRL +S>.

---

### T.1 Creating Load Case 3

In this procedure, you will add a load combination of the first two primary load cases.

If you started your model in STAAD.Pro Physical Modeler, first select the **Loading** page in the Analytical Modeling page control bar. The **Load & Definition** dialog opens on the right side of the program window.

Here you will see that the two load groups you created in STAAD.Pro Physical Modeler have each been added as primary load cases to the analytical model. The loads you added to the physical model are also transferred as load items in the respective load cases.

Load case 3 is a load combination. This means that the results from the primary load cases will be combined as directed by this load case definition.

1. On the **Loading** ribbon tab, select the **Combination Load Case** tool in the **Loading Specifications** group.

The **Create New Load Combinations** dialog opens.
2. Type 75 Percent of \([\text{DL+LL+WL}]\) in the Name field.

3. Set the Type option to Normal.

   This combines the loads algebraically.

   The other combination types available are called SRSS (square root of sum of squares) and ABS (Absolute). The SRSS type offers the flexibility of part SRSS and part Algebraic. That is, some load cases are combined using the square root of sum of squares approach, and the result is combined with other cases algebraically, as in:

   \[ A + \sqrt{B^2 + C^2} \]

   where \( A, B, \text{ and } C \) = the individual primary load cases

4. Type 0.75 in the Default \( \alpha_1 \) field.

   This is used as the default factor for normal load combinations.

5. Click [>>].

   Both primary load cases are added to the Load Case Definition list using the default factor.

   This indicates that the results of the two load cases will be multiplied by 0.75 and then summed to produce load combination results. Note that such a load combination method should only be used for linear analysis.
6. Click Add.
   The load combination is added to the **Load Cases Details** section in the **Load & Definition** dialog as load 3.

7. Click Close.

**T.1 Analysis and Design**

The following procedures describe how to add analysis and design commands to the STAAD input file.

**Note:** The analysis design commands are added using either the analytical user interface or the STAAD.Pro Editor. The STAAD.Pro Physical Modeler interface is not used to assign analysis and design commands.

**T.1 Specifying the analysis type**

A linear, static analysis is required for this model. You can also instruct STAAD.Pro to provide a static equilibrium report.

The STAAD input file commands generated are:

```
PERFORM ANALYSIS PRINT STATICS CHECK
```

1. On the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group.

The **Analysis/Print Commands** dialog opens.

**Tip:** If the **Analysis/Print Commands** dialog does not open automatically, then click **Define Commands** in the **Analysis - Whole Structure** dialog.

2. In the **Analysis/Print Commands** dialog, select the **Perform Analysis** tab.
3. Select the Statics Check option.

**Note:** In response to this option, a report consisting of the summary of applied loading and summary of support reactions, for each load case, will be produced in the STAAD output file.

4. Click Add.

**Tip:** The command is added to the list of commands outlined in the Analysis - Whole Structure dialog on the right-hand side of the window. The command has a green checkmark to indicate that it is valid. You can review the outline of the command input structure here.

5. Click Close.

**Tip:** Remember to save your work by either click **Save** on the File ribbon tab, the **Save** tool, or pressing `<CTRL+S>`.

T.1 Specifying post-analysis print commands

Once an analysis has been completed, the program can then provide results of the analysis in the output. In particular, you will request member end forces and support reactions written to the output file.
The STAAD input file commands generated are:

```
PRINT MEMBER FORCES ALL
PRINT SUPPORT REACTION LIST 1 4
```

1. Select all the beam members by one of the following methods:
   - on the Select ribbon tab, select the All tool in the Beams group
   - click-and-drag a window around all members in the View window
   - press <Ctrl+A>

2. On the Analysis and Design ribbon tab, select the Post-Analysis Commands tool in the Analysis Data group.

3. On the Post Analysis Print - Whole Structure dialog, click Define Commands. The Analysis/Print Commands dialog opens.

4. Add the member forces results to the output:
   - a. Select the Member Forces tab.
b. Click **Assign**.

**Tip:** Since you first selected the members, you can assign the command to those members directly from this dialog. Otherwise, you would add the command and then assign it —similar to how you assigned load case items— to those members.

c. Click **Close**.

5. On the **Select** ribbon tab, select the **Supports** tool in the **Nodes** group.

The supported nodes (nodes 1 and 4) are both selected.

6. Repeat steps 2 and 3 to open the **Analysis/Print Commands** dialog for the post-print commands.

7. Add the support reactions to the output:

a. Select the **Support Reactions** tab.
b. Click **Assign**.

c. Click **Close**.

The command is added to the list of commands.
Figure 25: The **Post Analysis Print** dialog after the post-analysis print commands are added and assigned.
**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL +S>`.

### T.1 Short-listing the load cases to be used in steel design

The steel design has to be performed for load cases 1 and 3 only per the specification at the beginning of this tutorial. To instruct the program to use just these cases, and ignore the remaining, you will use the **LOAD LIST** command.

The STAAD input file commands generated are:

```
LOAD LIST 1 3
```

1. On the **Analysis and Design** ribbon tab, select the **Load List** tool in the **Analysis Data** group.

   The **Load List** dialog opens.

   ![Load List Dialog](image)

   *Figure 26:*

2. From the **Load Cases** list box on the left, double-click on **1: DEAD + LIVE** and **3: 75 Percent of [DL+LL+WL]** to add these loads to the **Load List** box on the right.

3. Click **OK**.

### T.1 Specifying steel design parameters

Designing members per a building code as specified for this tutorial require you to provide values for some of the terms where the default values do not match the problem requirements.

**Note:** This tutorial uses the 2010 edition of the American Institute of Steel Construction 360 specification for design (AISC 360-10). Details on the code parameters can be found in [Section 1 of the Design Codes](#) (on page 1366) section.
The STAAD input file commands generated are:

```
PARAMETER
CODE AISC UNIFIED 2010
FYLD 7200 ALL
TRACK 2 MEMB 2 3
UNB 10.0 MEMB 2 3
UNT 10.0 MEMB 2 3
SELECT MEMB 2 3
```

1. On the Analysis and Design ribbon tab, select Steel in the Design Commands gallery.

2. In the Steel Design - Whole Structure dialog, select AISC 360-10 in the Current Code list.

3. In the Steel Design - Whole Structure dialog, click Define Parameters. The Design Parameters dialog opens.
4. Specify the yield strength parameter:
   a. Select the FYLD parameter tab.
b. Type 7200 (kip/ft$^2$) [50 (kip/in$^2$)] in the Yield strength of steel field.

Tip: This equates to a 50 ksi steel, which is the common strength for American wide flange shapes. You can change the input units before and after this command to use inches for convenience, but this tutorial uses a non-standard unit here for brevity.

c. Click Add.
The parameter list is added to the list of commands in the Steel Design - Whole Structure dialog, including the selected design code and the yield strength value.

5. To define the remaining parameters, repeat step 4 except for selecting the parameters and providing the values listed below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRACK</td>
<td>2 (select the option)</td>
</tr>
<tr>
<td>UNB</td>
<td>10 (ft) [120 (in)]</td>
</tr>
<tr>
<td>UNT</td>
<td>10 (ft) [120 (in)]</td>
</tr>
</tbody>
</table>

6. Click Close in the Design Parameters dialog.

Note: The steel design parameters are all marked with an icon. This indicates that they need to be assigned to steel members.

7. Assign the yield strength to all members:
   a. Select the FYLD 7200 parameter in the command list.
b. Select the **Assign to View** option in the Assignment Method group.

c. Click **Assign**.

A dialog opens confirming you want to assign to the view (all members currently displayed in the view window).

d. Click **Yes**.

8. Assign the output detail (TRACK) parameter to members 2 and 3:

   a. Select the **TRACK 2** parameter in the command list.

   b. Select the **Use Cursor to Assign** option in the Assignment Method group.

   c. Click **Assign**.

      The mouse pointer changes to a ⬅️.

   d. Click on each member in the Frame.

   e. Click on **Assigning** to stop assigning design parameters.

9. Repeat step 8 to assign the other two parameters (UNB and UNT) to members 2 and 3, as well.
Figure 27: The **Steel Design - Whole Structure** dialog after the design parameters have been added and
10. Add a command to instruct select sizes for members 2 and 3:

The select command is an instruction to the program to assign the least-weight cross-section which satisfies all the code requirements for the member.

a. In the **Steel Design - Whole Structure** dialog, click **Commands**.

The **Design Commands** dialog opens.

b. Select the **Select** tab.

c. Click **Add**.

d. Click **Close**.

11. Assign the select command to members 2 and 3:

a. Select the **SELECT** parameter in the command list.

b. Select the **Assign to Edit List** option in the Assignment Method group.

c. Type **2 3** in the list.

Notice this is a space-separated list of member numbers.

d. Click **Assign**.

**Tip:** You may also use either the method of selecting the members first or using the cursor to assign the command to the members.

After the parameters are assigned, click anywhere in the drawing area to deselect the members.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL+S>`.
T.1 Re-specifying the analysis command

When the analysis and design engine executes the member selection operation you specified in the previous step, a new set of properties will end up being assigned to those members. This changes the stiffness distribution for the entire structure. Since the structure is statically indeterminate, it should be analyzed again to determine the correct the nodal displacements, member forces, etc. to reflect this new stiffness distribution.

The STAAD input file commands generated are:

```
PERFORM ANALYSIS
```

1. Select the Select command in the Analysis - Whole Structure dialog outline of the model commands.
2. On the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group.

The Analysis/Print Commands dialog opens.

**Tip:** If the Analysis/Print Commands dialog does not open automatically, then click Define Commands in the Analysis - Whole Structure dialog.

3. Select the Perform Analysis tab.
4. Select the No Print option.

**Tip:** The statics check report does need to be repeated.

5. Check the After Current option.
   This allows you to specify that where the new command is added. This will place the new Perform Analysis after the command selected in Step 1, instead of in the first valid point within the model file.
6. Click Add.
7. Click Close.

**Tip:** Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL+S>.

T.1 Re-specifying the TRACK parameter

The final calculation we need to do is make sure the current set of member properties pass the code requirements based on the up-to-date member forces.

This will require that we do a code checking operation again. To restrict the output produced to a reasonable level, we specify the TRACK parameter again but use a different value.

The STAAD input file commands generated are:

```
PARAMETER
CODE AISC UNIFIED 2010
TRACK 0 ALL
```

1. On the Analysis and Design ribbon tab, select Steel in the Design Commands gallery.
2. In the Steel Design - Whole Structure dialog, click Define Parameters.
   The Design Parameters dialog opens.
3. Specify the track parameter:
   a. Select the TRACK parameter tab.
   b. Select option 0.
      
      **Note:** The TRACK 0 command instructs the program to only provide the controlling limit state check for each member assigned to this command.
   c. Click Add.
      The parameter list is added to the list of commands in the Steel Design - Whole Structure dialog, including the selected track parameter and value.
   d. Click Close.
4. Select the TRACK 0 parameter entry in the list of commands.
5. Select all the beam members by one of the following methods:
   on the Select ribbon tab, select the All tool in the Beams group

   or

   click-and-drag a window around all members in the View window
   or

   press <Ctrl+A>
6. In the Steel Design - Whole Structure dialog, select the Assign To Selected Beams option.
7. Click Assign.
   A message dialog prompting you to confirm the assignment.
8. Click Yes.

After the parameters are assigned, click anywhere in the drawing area to deselect the members.

**Tip:** Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL+S>.

**T.1 Specifying the CHECK CODE command**

As part of the iterative process of analysis and design, you must perform a code check on the selected members after they have been analyzed. This ensures that the new set of member forces do not exceed the capacity of the selected members.
A code checking operation which uses the up-to-date cross sections of the members and the latest member forces is used to evaluate that the members have sufficient capacity per the code specifications.

The STAAD input file commands generated are:

CHECK  CODE  ALL

1. In the Steel Design - Whole Structure dialog, click Commands. The Design Commands dialog opens.
2. Select the Check Code tab.

![Design Commands dialog](image)

3. Click Add.
4. Click Close.
5. Select the unassigned CHECK CODE entry in the Steel Design - Whole Structure dialog.
6. Select the Assign to View option in the Assignment Method group.
7. Click Assign. A message dialog prompting you to confirm the assignment.
8. Click Yes.

Tip: Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL+S>.
T.1 Viewing the input command file

You can inspect the text data file created during this tutorial.

1. On the Utilities ribbon tab, select the Command File tool in the Edit group.

The STAAD.Pro Editor opens with the contents of the input file.

2. (Optional) You modify the data of the structure in this editor if necessary.

3. Select File > Exit Editor in the STAAD.Pro Editor window to close.

As stated in "Methods of creating the model" (on page 373), you could also have created the same model by typing the relevant STAAD commands into a text file using the STAAD.Pro Editor. If you would like to understand that method, proceed to the next section.

If you want to skip that part, proceed to "Performing Analysis and Design" (on page 432) where you will perform the analysis and design on this model.
T.1 Creating the model using the command file

As an alternative to the procedures described in the preceding tutorial, you can also create the same STAAD input file using the STAAD.Pro Editor.

**Note:** A STAAD input file is a plain text file that uses the `.std` file extension. Therefore any standard text editor such as Notepad can also be used to create the command file. However, the STAAD.Pro Editor offers the advantage of syntax checking as you type the commands. The STAAD command syntax are highlighted by command, keyword, value, etc.

To start a new STAAD input file using the STAAD.Pro Editor, follow the procedure described in “Creating a new structure” (on page 375), except select the **Open STAAD Editor** check box in step 7. The STAAD.Pro Editor window opens with the basic commands for your model entered.

For this tutorial, delete all the command lines displayed in the editor window and type the lines shown below. While not necessary, this will allow you to learn more about the required and optional command lines for an input file.

STAAD commands are **not** case sensitive (i.e., they may be typed in upper or lower case letters). By convention, this and most input files use all caps, though.

For most all commands and keywords, the first three letters of a keyword are all that are needed. The rest of the letters of the word are not required, but are useful to present a user-friendly command language in mostly plain
English for later reference. By convention, the required letters in a command or keyword are underlined here ("PLANE" = "PLA" = "plane" = "pla").

**STAAD PLANE PORTAL FRAME**

Every STAAD input file has to begin with the word **STAAD**. The word **PLANE** signifies that the structure is a plane frame (in the XY plane). The remainder of this line is the title of the problem, which is optional.

**Note:**

If a line is typed with an asterisk in the first column, it signifies that the line is a comment line and should not be executed. For example, one could have put the optional title above on a separate line as follows:

```
* PORTAL FRAME
```

**UNIT FEET KIP**

Specify the force and length units for the commands to follow.

**JOINT COORDINATES**

```
1 0. 0. ; 2 0. 15. ; 3 20. 15. ; 4 20. 0.
```

Joint numbers and their corresponding global X and Y coordinates are provided above. For example, 3 20 15. indicates that node 3 has an X coordinate of 20 ft and a Y coordinate of 15 ft. Note that the reason for not providing the Z coordinate is because the structure is a plane frame. If this were a space frame, the Z coordinate would also be required.

Semicolons (;) are used as line separators. In other words, data which is normally put on multiple lines can be put on one line by separating them with a semicolon.

**MEMBER INCIDENCE**

```
1 1 2 ; 2 2 3 ; 3 3 4
```

The members are defined by the joints to which they are connected.

**MEMBER PROPERTY AMERICAN**

```
1 3 TABLE ST W12X35
2 TABLE ST W14X34
```

Members 1 and 3 are assigned a W12X35 section from the built-in AMERICAN steel table. Member 2 has been assigned a W14X34. The word ST stands for standard single section. Sections 5.20.1 through 5.20.5 of the STAAD Technical Reference help explain the convention for assigning member property names.

**UNIT INCHES**

**DEFINE MATERIAL START**

```
ISOTROPIC STEEL
E 29000
POISSON 0.3
DENSITY 283e-006
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 36 FU 58 RY 1.5 RT 1.2
END DEFINE MATERIAL
```

The length unit is changed from FEET to INCHES to use familiar units for most of the material definition. For this example, you use a set of built-in values for steel, so the units are only shown for convenience here. In the user
interface, units were not changed until the following commands were generated. See Section 5.26.1 of the STAAD Technical Reference help for more information.

```
MEMBER OFFSET
  2  START  6.0  0.  0.
  2  END   -6.0  0.  0.
```

The beam member is physically connected to the 2 columns at the face of the column, and not at the column centerline. This creates a rigid zone, about half the depth of the columns, at the 2 ends of the beam 2. This rigid zone is taken advantage of using member offsets (It is you choice whether or not you wish to use these). So, the above commands define that member 2 is eccentrically connected or OFFSET at its START joint by 6 inches in the global X direction, 0.0 and 0.0 in Y and Z directions. The same member is offset by negative 6.0 inches at its END joint. See Section 5.25 of the STAAD Technical Reference help for more information.

```
PRINT MEMBER INFORMATION ALL
```

The information that is printed by this command includes start and end joint numbers (incidence), member length, beta angle and member end releases.

```
SUPPORTS
  1  FIXED ; 4  PINNED
```

A fixed support is located at joint 1 and a pinned support (fixed for translations, released for rotations) at joint 4. More information on the support specification is available in Section 5.27 of the STAAD Technical Reference help.

```
UNIT FT
```

The length unit is changed to FEET to facilitate input of loads.

```
LOADING 1 DEAD + LIVE
MEMBER LOAD
  2  UNI  GY -2.5
```

The above commands identify a loading condition. DEAD + LIVE is an optional title to identify this load case. A Uniformly distributed MEMBER LOAD of 2.5 kips/ft is acting on member 2 in the negative global Y direction. Member Load specification is explained in Section 5.32 of the STAAD Technical Reference help.

```
LOADING 2 WIND FROM LEFT
JOINT LOAD
  2  FX  10.
```

The above commands identify a second load case. This load is a JOINT LOAD. A 10 kip force is acting at joint 2 in the global X direction.

```
LOAD COMBINATION 3 75 PERCENT OF (DL+LL+WL)
  1 0.75  2 0.75
```

This command identifies a combination load with an optional title. The second line provides the components of the load combination case - primary load cases and the factors by which they should be individually multiplied.

```
PERFORM ANALYSIS PRINT STATICS CHECK
```

This command instructs the program to proceed with the analysis and produce a report of static equilibrium checks. Section 5.37 of the STAAD Technical Reference help offers information on the various analysis options available.

```
PRINT MEMBER FORCES ALL
PRINT SUPPORT REACTION LIST 1 4
```
The above print commands are self-explanatory. The member forces are in the member local axes while support reactions are in the global axes.

```
LOAD LIST 1 3
PARAMETERS
  CODE AISC UNIFIED 2010
  FYLD 7200 ALL
  TRACK 2.0 MEMB 2 3
  UNB 10.0 MEMB 2 3
  UNT 10.0 MEMB 2 3
SELECT MEMBER 2 3
```

The above sequence of commands is used to initiate the steel design process. The command PARAMETERS is followed by the various steel design parameters. Parameters are specified typically when their values differ from the built-in program defaults. Specifications of the AISC Unified Code LRFD specification are to be followed. A parameter list for the AISC code is available in Section 3 of the Technical Reference help. ALL members have 10 ft unsupported length for the top and bottom flange (UNT and UNB).

UNT and UNB are used to compute the allowable compressive stress in bending. The yield strength of steel is specified as 7,200 ksf (50 ksi) since it is different from the default value of 36 ksi. The TRACK parameter controls the level of description of the output, 2.0 being the most detailed. The LOAD LIST command lists the load cases (1 and 3) to be used in the design. The SELECT MEMBER command asks the program to evaluate the most economical section for members 2 and 3 in the context of the above analysis.

PERFORM ANALYSIS

When the analysis & design engine executes the member selection operation specified in the member selection, a new set of properties will end up being assigned to those members. This has the effect of changing the stiffness distribution for the entire structure. Since the structure is statically indeterminate, it is best practice to re-analyze it to determine the accurate nodal displacements, member forces, etc. which reflect this new stiffness distribution. The above command instructs the program to do another cycle of analysis.

```
PARAMETER
  TRACK 0 ALL
```

The TRACK parameter is re-specified. It controls the level of information produced in the steel design output. This time, the value of 0 is used to provide a pass or fail status for each member.

CHECK CODE ALL

The analysis operation carried out earlier will create a new set of member forces. These forces will very likely be different from those which were used in the member selection operation. Consequently, you should verify that the structure is safely able — from the standpoint of the design code requirements — to carry these new forces. A code checking operation, which uses the up-to-date cross sections of the members, and the latest member forces, will provide a status report on this issue.

FINISH

A STAAD run is terminated using the FINISH command.

Save the input file and close the editor. The model is opened in the STAAD.Pro interface.

This concludes the session on generating the model as a command file using the built-in editor. If you wish to perform the analysis and design, you may proceed to the next section of this manual (on page 432). The post-processing facilities are explained in Post Processing (on page 441).

**Caution:** Remember that without successfully completing the analysis and design, the post-processing facilities will not be accessible.
T.1 Performing Analysis/Design

STAAD.Pro performs Analysis and Design simultaneously.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL + S>.

1. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group.

The **STAAD Analysis and Design** dialog opens and displays messages of the analysis progress.

![STAAD Analysis and Design dialog](image)

2. Select the **View Output File** option once the analysis and design are complete.

The three options are indicative of what will happen after you click **Done**.
View Output File

This option opens the output file created by STAAD. The output file contains the numerical results produced in response to the various input commands specified during the model generation process. It also provides you with important messages of any errors that were encountered, and if so, whether the analysis and design was successfully completed or not. See T.1 Viewing the output file (on page 433) for details on viewing and understanding the contents of the output file.

Go to Post Processing Mode

This option opens the graphical Post-processor mode, which can be used to extensively review and verify the results. This mode allows you to view the results graphically, plot result diagrams, produce reports, etc. See T.1 Post-Processing (on page 441) for details on the Post processing mode.

Stay in Modeling Mode

This option closes the dialog and remains in the Model generation mode of the program, where you initiated the analysis. This is useful if you want to make further changes to the input file.

3. Click Done.
   The STAAD.Pro Output Viewer window opens.

T.1 Viewing the output file

During the analysis process, STAAD.Pro creates an Output file. This file provides important information on whether the analysis was performed properly.

For example, if STAAD.Pro encounters an instability problem during the analysis process, it will be reported in the output file.

**Note:**
If you did not select to open the output file after running the analysis in the previous procedure, you can open it any time through the user interface. On the **Utilities** ribbon tab, select the **Analysis Output** tool in the **View** group.

**Tip:** By default, the output file contains a listing of the entire input also. You may choose not to print the echo of the input commands in the Output file. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands > Set Echo** tool option from the menu bar and select the **Echo Off** option in the **Set Echo** dialog.

It is **strongly recommended** that you review the entire output file to ensure that the results are reasonable and that there are no error messages or warnings reported, etc. Errors encountered during the analysis & design can disable access to the post-processing mode. The information presented in the output file is a crucial indicator of whether or not the structure satisfies the engineering requirements of safety and serviceability.

T.1 Post-Processing

STAAD.Pro offers extensive result verification and visualization facilities. These facilities are accessed from the Post Processing Mode. The Post Processing mode is used to verify the analysis and design results and generate reports.

T.1 Opening the postprocessing workflow

You can open the Postprocessing workflow anytime there are current analysis results for your model.

If you selected to open the Postprocessing workflow after T.1 Performing Analysis/Design (on page 432), then you can skip to step 2.

1. On the Workflows panel, select Postprocessing.
The Results Setup dialog opens.

2. (Optional) Select the load cases for which to display the results.

   **Tip:** All load cases are selected by default.

   For this tutorial, we will use all load cases.

3. Select the Result View Options tab and then check the Enable Automatic Scaling option.

4. Click OK.

   **Note:**
   Notice that in the Postprocessing workflow, the Postprocessing page control bar is opens above the view window. The ribbon bar updates to include the Results ribbon tab.

T.1 Annotating the displacements

Annotation is the process of displaying the displacement values on the screen.

1. Select the Displacements page in the Postprocessing page control bar.

   The diagram displayed is the node deflection diagram for load case 1 (DEAD + LIVE).

2. On the Results ribbon tab, select the Annotate tool in the Configuration group.
The Annotation dialog opens.

3. From the Ranges tab, select All.

   **Tip:** If you want to annotate deflection for just a few nodes, specify the node numbers in the node list.

4. Select the Node tab and then check the Resultant option.

   The resultant is the square root of sum of squares of values of X, Y and Z displacements.
5. Click the **Annotate**.
   The values appear on the structure.

6. Click **Close**.

---

**Figure 31:**

**Figure 32:** The deflected shape diagram for load case 1
T.1 Displaying force and moment diagrams

1. Select the Beam Results page in the Postprocessing page control bar.

   The bending moment MZ is plotted by default. Note that the Mz tool in the View Results group on the Results ribbon tab is depressed (active).

2. (Optional) Change the force or moment diagram drawn on the structure in the Diagrams dialog:
   a. Right-click in the view window and then select Structure Diagrams from the pop-up menu. The Diagrams dialog opens.
   b. Select the Loads and Results tab.
   c. Select a different Load Case from the drop-down list.
   d. Select one or more options in the Beam Forces group.
      For example, select the Shear yy to display the shear force diagrams in the local y direction on the members.
   e. (Optional) Click on the color block adjacent to any of the force or moment options to change the color for that diagram.
   f. (Optional) The Beam Forces Diagram options control how the diagrams are filled.

   Tip: Alternatively, you can select which diagrams are displayed and for which load case using the tools and load cases selection in the View Results group on the Result ribbon tab.

3. On the Results ribbon tab, select the Annotate tool in the Configuration group.
4. From the Ranges tab, select All.
   
   **Tip:** If you wish to annotate the force/moment for just a few members, specify the beam numbers in the beam list.

5. Select the locations where you want to display results:
   
   a. Select the Beam Results tab
   
   b. Check the Ends and Mid point options in the Bending group.
6. Click **Annotate**.

The diagram is updated with annotated values displayed at the selected locations.
7. Click Close.

T.1 Displaying the dimensions of the members

1. On the Utilities ribbon tab, select the Beam Tools > Dimension Beams tool in the Geometry Tools group.

The Display/Remove Dimension dialog opens.

2. Select the Dimension to View option.
3. Click Display.
4. Click Close.
   The dimensions of the members will appear alongside the members.

T.1 Update physical model with design results

If you generated the model geometry using a physical model, then you need to update the physical model with design results.

Since you performed a member selection as part of the member design in the analytical model, the sections need to be updated in the physical model to keep it synchronized. STAAD.Pro Physical Modeler will detect that design results are present and prompt you to do this.

1. Select Physical Modeling workflow in the Workflows panel.

   The STAAD.Pro Physical Modeler window opens and the Member Design Selection dialog opens.

2. Click the Profile selection drop-down.
   The member design results table opens.

   **Note:** Here you can review the different analytical member design results for each physical member. Recall that a physical member may be decomposed into multiple analytical members and each of those may have different design results in STAAD.Pro (unless the FIXED GROUP command is used).
3. Click **Accept**.
The table closes.

4. Click **Commit**.
The dialog closes and the physical model is updated with the new sections from the STAAD.Pro steel design results.

## T.2 - RC Framed Structure

This tutorial provides step-by-step instructions for creating the model of a reinforced concrete framed structure using STAAD.Pro.

### T.2 Methods of creating the model

As explained in "[T.1 Methods of creating the model](on page 373)", there are three methods of creating the structure data:

1. **Using the STAAD.Pro Physical Modeler interface** (on page 452),
2. **using the traditional STAAD.Pro analytical modeling interface** (on page 458),
3. and **using the command file** (on page 495).

All three methods are explained in this tutorial.

### T.2 Description of the tutorial problem

The structure for this project is a 2 bay, 2 story reinforced concrete frame. The figure below shows the structure. The purpose of this tutorial is to create the model, assign all required input, and perform the analysis and concrete design.
**Figure 34:**

**Basic Data for the Structure**

<table>
<thead>

</tbody>
</table>
### T.2 Creating a new structure

On the Start page **New** tab, you will provide some initial data necessary for building the model.

1. On the Start page, select **New**.
   
   The **New** page opens to the **Model Info** tab.

2. **Type as** **RCFrame** in the **File Name** field.

3. **Specify a Location** where the STAAD input file will be located on your computer or network.

   You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.

|                    | Design columns 1, 3 and 4  |
4. Select **Physical** for the **Type** of model.
   This option selects the modeling method you want to use:

   **Analytical**  For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.

   **Physical**  For creating a model using the STAAD.Pro Physical Modeler interface.

   **Building**  For creating a building model structure using the Building workflow.

5. Select **Metric** as the system of **Units**.

   **Tip:** The units can be changed later if necessary, at any stage of the model creation.

6. (Optional) Select the Job Info tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.

7. Click **Create**.

   The STAAD.Pro modeling environment opens and your model file is then opened in the STAAD.Pro Physical Modeler.

   Alternatively, if you want to use either the analytical modeling workflow or the command input file editor to create the model, choose **Analytical**, click **Create**, and then proceed to either "T.1 Creating the model using the analytical user interface" or "T.2 Creating the model using the command file" respectively.

T.2 Creating the Model using the Physical Modeler

You are now ready to start building the model geometry. The steps for doing this are described in the following sections.

   **Tip:** Refer to the STAAD.Pro Physical Modeler Application Window Layout for reference on the application window.

T.2 Generate the model geometry

1. On the **Model** ribbon tab, select the **Grid** tool in the **Create** group.

   The **Create Grid** dialog opens.

2. Supply the grid details:
   a. Type Grid 1 in the **Name** field.
   b. Leave the **Plane** selection as XY and the **Creation Method** as By Spacing.
   c. Type 6 in the **Number of spaces in X** and 1 m in the **Grid spacing X** fields.
   d. Type 7 in the **Number of spaces in Y** and 0.5 m in the **Grid spacing Y** fields.
3. Use the **Member** tool to create the first portal frame:
   a. On the **Model** ribbon tab, select the **Member** tool in the **Create** group.

   ![Member tool]

   b. Click on the following points on Grid 1, in sequence.
      Double-click the final point to stop creating connected members.
      
      \[
      (0,0,0) \\
      (0,3.5,0) \\
      (6,3.5,0) \\
      (6,0,0) \\
      \]

   c. Select the **Member** tool again to deactivate the tool.

   **Note:** Refer to [T.1 Generating the model geometry](on page 377) in Tutorial 1 for detailed steps on how to draw a portal frame.

4. On the **View** ribbon tab, select the **Grids** tool in the **Reference** group.

   ![Grid tool]

   The tool is no longer highlighted and all grids are hidden in the display.

5. Switch on the node and beam labels:
   a. On the **View** ribbon tab, select the drop-down list below the **Numbering** tool in the **Model** group.

   ![Numbering tool]

   b. Select **Node** and **Member** on this list.
      They are both marked with a check.

   c. Select the **Numbering** tool.

6. On the **Model** ribbon tab, select the **Circular Copy** tool in the **Edit** group.

   ![Circular Copy tool]

   The **Copy Model Circular** dialog opens.

7. Specify the circular copy details:
   a. Leave the **Method** selection as **Global**.
   b. Select **Y** as the **Axis of rotation**.
   c. Type \(6 \text{ m}\) in the Pivot point **X** field.
   d. Type \(90 \text{ deg}\) in the **Arc angle** field.
   e. Type **1** in the **Copies** field.
   f. Click **OK**.
The dialog closes and the selection elements of the portal frame are copied at 90° from the right end. 

8. In the lower, right corner of the view window, click the **Switch to isometric view** tool to display the frame in an isometric view.

**T.2 Assign user-defined concrete material**

If you don’t still have all the members selected, press `<Ctrl+A>`.

1. On the **Member Tools** ribbon tab, select the **Material** tool in the **Assign properties** group.

   The **Assign material** dialog opens.

2. Select the concrete specification:
   a. Select **Custom** from the **Type** drop-down list.
      
      Leave the **Source** as **Catalog** and the **Country** as **United States**.
   b. Select **CONCRETE_ACI318** from the **Material type** drop-down list.

3. Define the custom lightweight concrete material:
   a. Type 0.17 in the **Mu** field (Poisson’s ratio).
   b. Type 0.1E-6 in the **Alpha** field (coefficient of thermal expansion).
   c. Type 0.05 in the **CDAMP** field (composite damping ratio)
   d. Type 25 N/mm2 in the **Fck** field (concrete ultimate strength).
   
      **Tip:** You can type any appropriate unit in any unit system into the field and it will automatically be converted to the current default units.

   e. Type 19080 N/m3 in the **Gamma** field (material density).
   f. Type **CONCRETE-LTW** in the **Name** field.
   g. Click **OK**.

   The **CONCRETE-LTW** material is assigned to all the members. This material is also added to the model catalog for later use if necessary.

On the **Model** ribbon tab, select the **Catalog** tool in the **Catalog** group. The model catalog window opens.

Select the **Material** tool so it is highlighted in the display control toolbar found in the lower-left corner. The **CONCRETE-LTW** material is shown as a tile in the Materials section. Select this tile to review the material values. You can use this interface to make changes to the custom materials and sections in your model.

Once you are done reviewing, click the back arrow in the top-left corner of the window.

**T.2 Assign the member properties**

1. While holding `<Ctrl>`, click on both the end columns (M1 and M4).
2. On the **Member** ribbon tab, select the **Section** tool in the **Assign properties** group.
The Assign Section dialog opens.

3. Define the rectangular column section:
   Leave the Source selection as Catalog.
   a. Select Prismatic in the Type drop-down list.
      Leave the Source selection as Catalog.
   b. Select Solid Rectangle in the Shape drop-down list.
   c. Select RECT in the Template drop-down list.
   d. Type 300 mm in the YD field and 275 mm in the ZD field.
   e. Type RECT-COL in the Name field.
   f. Click OK.

4. Repeat steps 1-3 except to define a 350mm (depth, YD) by 275 mm (width, ZD) rectangular prismatic section named RECT-BEAM to the beam members (M2 and M5).

5. Repeat steps 1-3 again except to define a 350mm diameter (YD) solid circular prismatic section named CIRC-COL to the middle column (M3).

6. Rotate the right column by 90 deg (Beta angle):
   a. Select the right column (M4).
   b. On the Member Tools ribbon tab, select the Rotate tool in the Edit group and then select Rotate 90° from the list.

The column is rotated about its local 1 axis by 90°.

c. On the View ribbon tab, select the Local Axes tool in the Model group.

You can confirm that the local z axis of M4 is now rotate 90° away from the global Z axis.

T.2 Assign supports

1. Orient the view to front view:
   a. (Optional) If the rotation controls are hidden, click the rotation widget in the lower-right corner of the view window.
   b. Select the Switch to front view tool.
   c. (Optional) Click the rotation widget again to hide the controls.
Tip: Alternatively, you can press and hold the right mouse button and drag the mouse pointer to quickly rotate the view so it is easy to select the column bases.

2. Click and drag a box from the right side of the to the left to enclose the column base nodes (N1, N4, and N5).

3. On the Node ribbon tab, select the Fixed tool in the Supports group.

A fixed support is assigned to the selected nodes.

T.2 Assign loads to load cases

1. On the Spreadsheet ribbon tab, select the Load Cases tool in the References group.

The Load Cases spreadsheet opens.

2. For Load 1:
   a. Type Dead Load in the description field of Load case 1.
   b. Select Dead as the Type.
   c. Type -1 in the Self-weight multiplier in field Y.

   Note: This value is negative.

   d. Press <Enter>.
3. Select the beam members (M2 and M5).
4. Add the uniform distributed dead load:
   a. On the Member ribbon tab, select the Distributed tool in the Loads group.

   The Add Member Distributed Load dialog opens. The Load group is already selected to use Load case 1.
   b. Select the Load type as Uniform.
   c. Select Global Y as the Direction.
   d. Type \(-400 \text{ kg/m}\) in the Magnitude field.

   Note: This value is negative and uses different units than the default, so be sure to type out the units as indicated above. It will be automatically converted into the default units of kN/m.
   e. Click OK.

5. Create the live load group:
   a. On the Model ribbon tab, select the Load Case tool in the Load group.

   The Add Load Case dialog opens.
   b. Type Live Load in the Description field.
   Leave the Name as Load Case 2.
   c. Select Live as the Type.
   Leave the self weight modifiers all as zero.
   d. Click OK.

   The live load case is added and selected as the active load case as indicated in the application status bar.

6. Repeat steps 3 and 4 except to add a uniform distributed load of \(-600 \text{ kg/m}\) (in the Global Y direction) to the beam members (M2 and M5).

7. Repeat steps 5 and 6 except to add a Load case 3 with a description of Wind Load and type of Wind.
   This load group will have the following to load items:
   • a uniform force of \(300 \text{ kg/m}\) in the Global X direction and is applied to the left column (M1).
   • a uniform force of \(500 \text{ kg/m}\) in the Global X direction and is applied to the right column (M4).

   Note: As this model uses a second-order, P-Delta analysis, load combinations are not recommended. Instead, repeat loads will be used to combine the load cases so that the combinations are processed by the analysis engine directly. These Repeat loads will be added in the Analytical Modeling workflow.

   Refer to TR.37.2 P-Delta Analysis Options (on page 2797) for further details on load types appropriate for P-Delta analysis.

T.2 Generate the Analysis Model

You have now completed the modeling portion of this tutorial. You will now send the model data back to STAAD.Pro where you will create load combinations, add output commands, select analysis criteria, and specify design parameters.
For this tutorial, you will use the default options for analytical model generation. However, for advanced models you can review and change those options in the Configuration dialog.

1. Select Save to save the physical model.
2. Either:
   - On the Model ribbon tab, select the Return to Analytical Modeling tool in the STAAD.Pro group
   - On the File ribbon tab, select Create analysis model in the backstage tabs

The Return to Analytical Modeling dialog opens and displays the progress of the analytical model being generated.

3. Click OK.
   - If you have not previously associated this model with a CONNECT Project, you are asked to do so. This is will not be necessary for this tutorial.
4. Click Cancel in the Assign Project dialog.

The STAAD.Pro Physical Modeler window closes and the model is loaded into the STAAD.Pro analytical modeling interface.

### T.2 Creating the model using the analytical user interface

The following procedures describe how to use the traditional STAAD.Pro analytical user interface to build the model. The steps and, wherever possible, the corresponding STAAD.Pro commands (the instructions which get written in the STAAD input file) are described in the following sections.

**Tip:** Refer to GS. Application Window Layout (on page 50) for reference on the application window.
T.2 Generating the model geometry

The structure geometry consists of joint numbers, their coordinates, member numbers, the member connectivity information, plate element numbers, etc.

The STAAD input file commands generated are:

```
JOINT COORDINATES
1 0.0 0.0 0.0 ; 2 0.0 3.5 0.0
3 6.0 3.5 0.0 ; 4 6.0 0.0 0.0
5 6.0 0.0 6.0 ; 6 6.0 3.5 6.0

MEMBER INCIDENCE
1 1 2 ; 2 2 3 ; 3 3 4 ; 4 5 6 ; 5 3 6
```

When starting in the Analytical Modeling workflow, a grid is initially displayed in the main view window. This grid is controlled by the **Snap Node/Beam** dialog. The directions of the global axes (X, Y, Z) are represented in the icon in the lower left hand corner of the drawing area.

![Figure 35: The STAAD.Pro window with the Snap Node/Beam dialog open](image)

**Note:** The **Snap Node/Beam** dialog opens on the right side of the screen. You can reopen this dialog by selecting the **Snap Grid Beam** tool in the **Structure** group on the **Geometry** ribbon tab.

1. On the **Snap Node/Beam** dialog, click **Create**.
   A dialog opens which will enable us to set up a grid.
   Within this dialog, there is a drop-down list from which you can select Linear, Radial, or Irregular form of grid lines.
Linear used to place the construction lines perpendicular to one another along a "left to right - top to bottom" pattern, as in the lines of a chess board.

Radial used to place construction lines to appear in a spider-web style, which makes it easy to create circular type models where members are modeled as piece-wise linear straight line segments.

Irregular used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane.

2. Select Linear, which is the Default Grid.

In this structure, the portion consisting of members 1 to 3, and nodes 1 to 4, happens to lie in the X-Y plane. Leave X-Y as the Plane of the grid. The size of the model that can be drawn at any time is controlled by the number of Construction Lines to the left and right of the origin of axes, and the Spacing between adjacent construction lines.

3. Type a Name of Grid 1.

4. Type 12 as the number of lines to the Right of the origin along X and 7 above the origin along Y.

5. Type a Spacing of 0.5 m between lines along both X and Y (see figure below) we can draw a frame 6m X 3.5m, adequate for our segment.

6. Click OK.

7. In the Snap Node/Beam grids list, check the new Grid 1 option.
You can create any number of grids. By providing a name, each new grid can be identified for future reference.

**Tip:** Please note that these settings are only used to generated construction lines. These construction lines enable you to easily draw the structure but do not restrict our overall model to those limits.

**Tip:** To change the settings of this grid, select the name in the Snap Node/Beam dialog and then click **Edit**.

The check by **Default Grid** is automatically cleared. STAAD.Pro will only display a single grid at a time.

8. In the View window, click at the origin (0, 0) to create the first node.
A line is "rubber-banded" between this node and the mouse pointer, which previews the member to placed with the next mouse click.

The Snap Node/Beam feature is active by default.

9. Click on the following points to create nodes and automatically join successive nodes by beam members.

(0, 3.5)
(6, 3.5)
(6, 0)

10. Click Close in the Snap Node/Beam dialog.
The grid is hidden.
It is very important that we save our work often, to avoid loss of data and protect our investment of time and effort against power interruptions, system problems, or other unforeseen events.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing <CTRL +S>.

**T.2 Copying Model Objects by Circular Repeat**

By examining the structure diagram for this tutorial exercise, you may have observed that members 4 and 5 can be easily generated if we could first create a copy of members 1 and 2 and then rotate those copied units about a vertical line passing through the point (6, 0, 0, that is, node 4) by 90 degrees. Fortunately, such a facility does exist which can be executed in a single step. It is called **Circular Repeat** and is available under the **Geometry** menu.

1. Right click anywhere in the view window and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens to the **Labels** tab.

2. Set the **Node Numbers** and **Beam Numbers** on and then click **OK**.
Tip: Alternatively, you can press <Shift+N> and then <Shift+B> to quickly toggle the same labels. The letters in parenthesis on the Labels tab indicate these <Shift> key shortcuts.

3. (Optional) You can change the font of the labels by selecting File > Settings > Display Options and then changing the corresponding label Font size in the Options dialog.

4. Select the first column and beam for copying:
   a. On the Select ribbon tab, select the Beam Cursor tool in the Cursors group.
b. Holding the <Ctrl> key, click on members 1 and 2.

5. On the Geometry ribbon tab, select the Circular Repeat tool in the Structure group.

The 3D Circular dialog opens.

6. Specify the circular repeat details:
   a. Select Y as the Axis of Rotation.
   b. Type 4 in the Node field.

   This is the node number through which the rotation axis will pass.

   **Tip:** You can click the Node Selection tool here and then click on the node you want the rotation axis to pass through in the View window.

c. Type 6 in the point X Coordinate field and type 0 in the point Z Coordinate field.

d. Type 90 in the Total Angle field.

e. Set the No of Steps value to 1.

f. Clear the Link Steps, Geometry Only, and Use this as the Reference Point for the Beta angle generation options.

g. Click OK.

7. Click anywhere away from the members in the View window to deselect the members.
Figure 39: The frame members drawn

Tip: Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL + S>.

T.2 Changing the input units of length

For specifying member properties for the structure, it is more convenient to use length units are millimeter instead of meter. This requires changing the current length units of input.

The STAAD input file commands generated are:

UNIT MMS KN

1. On the Geometry ribbon tab, select the Input Units tool in the Structure group.

The Set Input Units pop-up opens.
2. Select Metric as the Input Units.
3. Set the Length Units to Milimeter. Leave the Force Units set to KiloNewton.
4. Click Apply.

T.2 User-defined concrete material

The STAAD input file commands generated are:

```
DEFINE MATERIAL START
ISOTROPIC CONCRETE-LTW
E 22
POISSON 0.17
DENSITY 1.9e-008
TYPE CONCRETE
STRENGTH RY 1 RT 1 FCU 0.025
END DEFINE MATERIAL
```

You will create a material definition for a lightweight concrete to use for all members.

2. In the **Material - Whole Structure** dialog **Isotropic** tab, click **Create**.

The **Isotropic Material** dialog opens.
3. Input the required, user-defined material values for a lightweight concrete:
   a. Type CONCRETE-LTW in the Title field.
   b. Type 22 in the Young's Modulus (E) field.
   c. Type 0.17 in the Poisson's Ratio (nu) field.
   d. Type 1.9e-008 in the Density field.
   e. Select CONCRETE from Type of Material drop-down list.
   f. Type 0.025 in the Compressive strength (Fcu) field.

Leave the remaining property fields as zero for this tutorial exercise. The shear modulus is calculated based on E and Poisson's ratio and the thermal coefficient and critical damping default to zero. Refer to the TR.26.1 Define Material (on page 2501) for details.

**Tip:** The material definition can be edited later by selecting the material in the isotropic materials list and clicking Edit.

The new material is added to the Material table and the list of isotropic materials.

**T.2 Specifying member properties**

Next you will assign cross section properties for the beams and columns.
The STAAD input file commands generated are:

```
MEMB PROP
1 4 PRIS YD 300 ZD 275
2 5 PRIS YD 350 ZD 275
3 PRIS YD 350
...
MATERIAL CONCRETE-LTW ALL
```

1. Select the **Properties** page in the Analytical Modeling page control bar.

   ![Properties - Whole Structure dialog](image)

   **Figure 40:**

2. Either:

   - on the **Specifications** ribbon tab, click the **Prismatic** tool in the **Beam Profiles** group

   ![Prismatic tool](image)

   or

   - click **Define**
3. Define a 30 cm x 27.5 cm rectangular, concrete beam:
   a. Select the Rectangle tab.
   b. Check the Material option and select CONCRETE-LTW from the list.
      
      **Note:** This will automatically assign the user-defined material created in a previous procedure to the sections.
   c. Type 300 (mm) in the YD field.
   d. Type 275 (mm) in the ZD field.
   e. Click Add.

4. Repeat step 3 to define the beam member property, this time with a depth (YD) of 350 and a width (ZD) of 275.

5. Define a 35 cm round, concrete column:
   a. Select the Circle tab.
b. Check the **Material** option and select **CONCRETE-LTW** from the list.
c. Specify the diameter (YD) as **350 mm**.
d. Click **Add**.

6. Click **Close**.

7. Assign the 30 cm x 27.5 cm shape to members 1 and 4 (end columns):
   a. Select **Rect 0.30x0.28** in the list of sections.
   b. Select the **Use Cursor to Assign** option in the Assignment Method group.
   c. Click **Assign**.

   The mouse pointer changes to `I`

   d. In the view window, click on members 1 and 4.
   e. To stop assigning members, either:

   click **Assigning**

   or

   press the `<Esc>` key.

8. Repeat step 7 to assign the 0.35cm x 27.5 cm rectangular shape to members 2 and 5 (beams).

9. Repeat step 7 to assign the 0.35cm circular shape to members 3 (center column).
T.2 Specifying geometric constants

You need to orient member 4 so that its longer edges (sides parallel to local Y axis) are parallel to the global Z axis. This requires applying a beta angle of 90 degrees.

In the absence of any explicit instructions, STAAD.Pro will orient the beams and columns of the structure in a predefined way. Orientation refers to the directions along which the width and depth of the cross section are aligned with respect to the global axis system. The rules which dictate this default orientation are explained in General Engineering Theory (on page 2294).

The STAAD input file commands generated are:

```
BETA 90 MEMB 4
```

1. Select the Properties page in the Analytical Modeling page control bar.
   The Properties dialog opens.

2. On the Properties dialog, select the Beta Angle tab.

3. Click Create Beta Angle.
   The Beta Angle dialog opens.
4. Type 90 in the **Angle in Degrees** field.
5. Click **OK**.
   The property **Beta 90** is added to the beta angles list.
6. Select the property **Beta 90**.
7. Assign the beta angle to member 4:
   a. Select the **Use Cursor to Assign** option in the Assignment Method group.
   b. Click **Assign**.
      The mouse pointer changes to ↣
   c. In the view window, click on member 4.
   d. To stop assigning members, either:
      click **Assigning**
      or
      press the <Esc> key.
8. To view the orientation of the member local axes:
   right-click in the view window and select **Labels** from the pop-up menu, check the option for **Beam Orientation**, and click **Apply**.
   or
   press <Shift+O>.
Alternatively, you can assign a beta angle to a selected member set. On the Specification ribbon tab, select the Beam > Beta Angle tool in the Specifications group. Type the beta Angle in Degrees to use. Make sure that the To Selection option is selected and then click OK.

T.2 Specifying Supports

The base nodes of all the columns are restrained against translation and rotation about all the 3 global axes (i.e., fixed supports at those nodes).

The STAAD input file commands generated are:

```
SUPPORTS
1 4 5 FIXED
```

1. On the Select ribbon tab, select the Node Cursor tool in the Cursors group.

2. In the View window, hold <Ctrl> and click on nodes 1, 4, and 5 to select them.
3. In the Supports dialog, click Create.

   The Create Support dialog opens.
4. Select the **Fixed** tab (selected by default) and then click **Assign.**
5. Click any open space in the View window to deselect all selected nodes.

This prevents accidental assignment of unwanted data to those nodes.

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL + S>`.

T.2 Specifying Loads

Five load cases are to be created for this structure. Details of the individual cases are explained at the beginning of this tutorial.

The STAAD input file commands generated are:

```
UNIT METER KG
LOAD 1 DEAD LOAD
SELFWEIGHT Y -1
MEMBER LOAD
  2 5 UNI GY -400
LOAD 2 LIVE LOAD
MEMBER LOAD
  2 5 UNI GY -600
LOAD 3 WIND LOAD
MEMBER LOAD
  1 UNI GX 300
  4 UNI GX 500
LOAD 4 DEAD + LIVE
REPEAT LOAD
  1 1.2 2 1.5
LOAD 5 DEAD + WIND
```
T.2 Creating Load Cases 1, 2, and 3

The load values are listed in the beginning of this tutorial in kg and meter units. Rather than convert those values to the current input units, we will conform to those units.

STAAD.Pro does not allow to change the units while editing load cases. An error message is displayed if this is attempted.

Create the primary load cases for this model.

1. Change the force unit to **Kilogram** and the length unit to **Meter**.
   
   Refer to [T.2 Changing the input units of length](on page 466) for details.

2. On the **Loading** ribbon tab, select the **Primary Load Case** in the **Loading Specifications** group.

   ![Create New Primary Load Cases dialog](image)

   The **Create New Primary Load Cases** dialog opens.

3. Enter the properties for the first load case:
   
   a. Type **DEAD LOAD** in the **Title** field.
      
      Leave the **Number** as the default value of 1.

   **Note:** The **Loading Type** list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program’s automatically generating load combinations in accordance with those...
codes. Note that there is a check box labeled *Reducible per UBC/IBC*. This feature is active only when the load case is assigned a Loading Type called *Live* when you create that load case.

Since this tutorial does not use the automatic load combination generation feature, leave the **Loading Type** as **None**.

b. Click **Add**.
c. Click **Close**.

The load case appears under the **Load Cases Details** option in the **Load & Definition** dialog.

4. To create the selfweight dead load, either:

   on the **Loading** ribbon tab, select the **Load Items** tool
   a. Select the **1: DEAD LOAD** entry.

   ![Load & Definition dialog](image)

   **Figure 44:**

   b. Click **Add**.

   The **Add New Load Items** dialog opens with entries for adding load items to the selected load case.

5. Define the selfweight load:

   a. In the **Add New Load Items** dialog, select the **Selfweight Load** option under the **Selfweight** item.
   b. Select **Y** as the **Direction**.
   c. Type **-1.0** in the **Factor** field (multiplier for the calculated selfweight of members).
   d. Click **Add**.
6. With the Add New Load Items dialog still open, add the member loads to be applied to the beams:
   a. In the Add New Load Items dialog, select the Uniform Force tab under the Member Load item.
   b. Select GY as the Direction.

   **Tip:** For these members, since the local Y axis coincides with the global Y axis, selecting Y (local member Y) and GY (global Y direction) have the same effect. Press <Shift+O> to view the member orientation.

   c. Type -400 (kg/m) in the W1 field (magnitude of the uniform force).
      The negative value indicates the load acts "down".
      Leave the offset fields (d1 through d3) as zero.
   d. Click Add.
   e. Click Close.
7. Assign the selfweight load to all members:
   a. Select the **SELFWEIGHT Y -1** entry in the **Load & Definitions** dialog.

   ![Figure 46:](image)

   **Figure 46:**

   b. Select the **Assign to View** option.
   c. Click **Assign**.

   A message box opens prompting you to confirm you want to make this assignment.

   d. Click **Yes**.
   e. Click anywhere in the View window away from the members to deselect all members.

8. Assign the member load to members 2 and 5:
   a. Select the **UNI GY -400 kg/m** entry in the **Load & Definitions** dialog.
b. Press and hold <Ctrl> and then select members 2 and 5 in the View window.

   The **Beams Cursor** tool is automatically selected when the **Load & Definition** dialog is opened.

c. Select the **Assign to Selected Beams** option.

d. Click **Assign**.

   A message box opens to open prompting you to confirm you want to make this assignment.

e. Click **Yes**.

![Figure 48: Structure after uniform force is assigned to beams](image)

**Tip**: Use a scale of 6 kN/m per m for distributed forces if the loads are not visible or are too large for the View window when viewing the entire structure.

9. Repeat steps 3, 4, 6, and 8 to create a new load case titled **Live Load** which contains a uniform force of -600 kg/m in the global Y direction and is applied to members 2 and 5.

   **Note**: Be sure to select the **Live Load** on the **Loading** ribbon tab **Display** group to add load items to this load case.

10. Repeat steps 3 through 4 and then 6 through 8 to create a new load case titled **Wind Load** which contains the following two load items:

   **Note**: Be sure to select the **Wind Load** on the **Loading** ribbon tab **Display** group to add load items to this load case.

   a uniform force of +300 kg/m in the GX (global X) direction and is applied to member 1
   a uniform force of +500 kg/m in the GX (global X) direction and is applied to member 4
T.2 Analysis and Design

The following procedures describe how to add analysis and design commands to the STAAD input file.

**Note:** The analysis design commands are added using either the analytical user interface or the STAAD.Pro Editor. The STAAD.Pro Physical Modeler interface is not used to assign analysis and design commands.

T.2 Creating Load Cases 4 and 5

Use repeat load cases for the load combinations used in a nonlinear analysis.

Load cases 4 and 5 are to be generated using a combination load type called REPEAT LOAD (as opposed to a standard load combination). The instructions at the beginning of this tutorial specify using a PDelta analysis. A PDelta analysis is a non-linear type of analysis. In STAAD, to accurately account for the PDelta effects arising from the simultaneous action of previously defined horizontal and vertical loads, those previous cases must be included as components of the combination case using the REPEAT LOAD type.

1. On the **Loading** ribbon tab, select the **Primary Load Case** in the **Loading Specifications** group.

   ![Create New Primary Load Cases dialog](image)

   The **Create New Primary Load Cases** dialog opens.

---

*Figure 49: Structure after the wind load items are assigned*
2. Enter the properties for the load case:
   a. Type DEAD + LIVE in the Title field.
      Leave the Number as the default value of 4.

      **Note:** The Loading Type list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program's automatically generating load combinations in accordance with those codes. Note that there is a check box labeled Reducible per UBC/IBC. This feature is active only when the load case is assigned a Loading Type called Live when you create that load case.

   b. Click Add.
      The load case appears under the Load Cases Details option in the Load & Definition dialog.

3. To create the dead + live repeat load case:
   a. Select the 4: DEAD + LIVE entry.
Figure 50:

b. Click Add.

The **Add New Load Items** dialog opens with entries for adding load items to the selected load case.

4. Define the repeat load:
   a. In the **Add New Load Items** dialog, select the **Repeat Load** option under the **Repeat Load** item.
   b. Select **1: DEAD LOAD** as the **Available Load Cases** list and then click [>].
      This load is added as Load Case 1 in the **Repeat Load Definition** list.
   c. Type **1.2** in the **Factor** field for **Load Case 1** in the **Repeat Load Definition** list.
      This indicates that the load data values from load case 1 are multiplied by a factor of 1.2, and the resulting values are utilized in load case 4.
   d. Select **2: LIVE LOAD** as the **Available Load Cases** list and then click [>].
      This load is added as Load Case 2 in the **Repeat Load Definition** list.
   e. Type **1.5** in the **Factor** field for **Load Case 1** in the **Repeat Load Definition** list.
   f. Click Add.
Figure 51: Structure with repeat load case selected
5. Click Close.
6. Repeat steps 3 and 5 to create another repeat load case for load case 5, except:

   - title load case 5 **Dead + Wind**
   - add the Dead Load case with a factor of 1.1
   - add the Wind Load case with a factor of 1.3

**Note:** No member assignment is not necessary for repeat load cases. The members assigned to which the primary load cases are assigned are used for the repetition of the load.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL> +<S>`.

### T.2 Specifying the analysis type

The analysis type for this structure is called P-Delta.

Since this problem involves concrete beam and column design per the ACI code, second-order analysis is required and has to be done on factored loads acting simultaneously. The factored loads have been created earlier as cases 4 and 5. Now is the time to specify the analysis type.

The STAAD input file commands generated are:

```
PDELTA ANALYSIS SMALLDELTA
```

1. On the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group.

The **Analysis/Print Commands** dialog opens.

**Tip:** If the **Analysis/Print Commands** dialog does not open automatically, then click **Define Commands** in the **Analysis - Whole Structure** dialog.

2. Select the **PDelta Analysis** tab.
Note: Leave the parameters on this page as their default values and options.

3. Click Add.
4. Click Close.

Tip: Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL+S>.

T.2 Short-listing the load cases to be used in concrete design

The concrete design should only be performed for load cases 4 and 5 since those are the factored cases. Use the load list to instruct the program to use just these cases.

The STAAD input file commands generated are:

```
LOAD LIST 4 5
```

1. On the Analysis and Design ribbon tab, select the Load List tool in the Analysis Data group. The Load List dialog opens.
2. Press and hold the <Ctrl> key and then select load cases 4: DEAD + LIVE and 5: DEAD + WIND.
3. Click [>].
   Load cases 4 and 5 will be selected and placed in the Load List selection box.
4. Click OK.

T.2 Specifying concrete design parameters

Concrete design parameters allow you to directly specify some of the terms used in the equations for concrete member design.

For example, the grade of concrete or the maximum size of reinforcing bar you want to use.

Note: This tutorial uses the 2011 edition of the American Concrete Institute 318 specification for design (ACI 318-11). Details on the code parameters can be found in D1.F.3 Design Parameters (on page 1481).

The STAAD input file commands generated are:

```
UNIT MMS NEWTON
CODE ACI
CLB 30 ALL
CLS 25 ALL
CLT 25 ALL
FC 25 ALL
FYMAIN 415 ALL
TRACK 1 ALL
```

1. Set the force units as Newton and the length units as Millimeter.
   Refer to T.2 Changing the input units of length (on page 466) for details.
2. On the Analysis and Design ribbon tab, select Concrete in the Design Commands gallery.
The Concrete Design - Whole Structure dialog opens.

3. On the Concrete Design - Whole Structure dialog, select ACI 318 2011 from the Current Code drop-down list.

4. Click Define Parameters in the Concrete Design dialog.

The Design Parameters dialog opens.

5. Specify the clear cover on bottom:
   a. Select the CLB parameter tab.
   b. Type as 30 (mm) in the parameter value field.
   c. Click Add.

6. Repeat step 5 to define the remaining parameters:

Figure 54:
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLS</td>
<td>25</td>
</tr>
<tr>
<td>CLT</td>
<td>25</td>
</tr>
<tr>
<td>FC</td>
<td>25</td>
</tr>
<tr>
<td>FYMAIN</td>
<td>415</td>
</tr>
<tr>
<td>TRACK</td>
<td>1 (select option from list)</td>
</tr>
</tbody>
</table>

7. Click **Close**.

The **Concrete Design** dialog displays the parameters in the concrete design command.
Figure 55:
8. Assign these parameters to all the members in the model:
   a. Select the first unassigned parameter in the **Concrete Design | Whole Structure** dialog.
   b. Select the **Assign to View** option.
   c. Click **Assign**.
      
      A message dialog opens confirming you want to make this assignment.
   d. Click **Yes**.
   e. Repeat steps 8a though 8d for each unassigned parameter to assign them to all members.

T.2 Specifying design commands

Design commands are the actual instructions for the design of beams and columns.

The STAAD input file commands generated are:

```
DESIGN BEAM 2 5
DESIGN COLUMN 1 3 4
```

1. On the **Concrete Design - Whole Structure** dialog, click **Commands**.

   The **Design Commands** dialog opens.

   ![Design Commands dialog]

2. Select the **Design Beam** tab and then click **Add**.
3. Select the **Design Column** option and then click **Add**.
4. Click **Close**.
5. Assign the Design Beam command to the beams:
   a. Press and hold the <Ctrl> key and click members 2 and 5

   **Tip:** The Beams Cursor tool is selected when the Concrete Design - Whole Model dialog opens.

   b. Select the Assign to Selected Beams option.
   c. Click Assign.

   A message box opens prompting you to confirm you want to make this assignment.
   d. Click Yes.

6. Repeat steps 5 to assign the Design Column command to members 1, 3, and 4.

   **Tip:** Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL +S>.

T.2 Viewing the input command file

You can inspect the text data file created during this tutorial.

1. On the Utilities ribbon tab, select the Command File tool in the Edit group.

   The STAAD Editor window opens.
2. (Optional) You modify the data of the structure in this editor if necessary.
3. Select **File > Exit Editor** in the STAAD.Pro Editor window to close.

As stated in "**T.2 Methods of creating the model** (on page 449)", you could also have created the same model by typing the relevant STAAD commands into a text file using the STAAD.Pro Editor. If you would like to understand that method, proceed to the next section. If you want to skip that part, proceed to "**T.2 Performing the analysis and design** (on page 499)" where you will perform the analysis and design on this model.

**T.2 Creating the model using the command file**

As an alternatively to the procedures described in the proceeding tutorial, you can also create the same STAAD input file using the STAAD.Pro Editor.

**Note:** A STAAD input file is a plain text file that uses the .std file extension. Therefore any standard text editor such as Notepad can also be used to create the command file. However, the STAAD.Pro Editor offers the advantage of syntax checking as you type the commands. The STAAD command syntax are highlighted by command, keyword, value, etc.
To start a new STAAD input file using the STAAD.Pro Editor, follow the procedure described in "Creating a new structure" (on page 451), except select the Open STAAD Editor check box in step 7. The STAAD.Pro Editor window opens with the basic commands for your model entered.

For this tutorial, delete all the command lines displayed in the editor window and type the lines shown below. While not necessary, this will allow you to learn more about the required and optional command lines for an input file.

STAAD commands are not case sensitive (i.e., they may be typed in upper or lower case letters). By convention, this and most input files use all caps, though.

For most all commands and keywords, the first three letters of a keyword are all that are needed. The rest of the letters of the word are not required, but are useful to present a user-friendly command language in mostly plain English for later reference. By convention, the required letters in a command or keyword are underlined here ("PLANE" = "PLA" = "plane" = "pla").

**STAAD SPACE RC FRAMED STRUCTURE**

Every input has to start with the word STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

```
UNIT METER KN
```
Specifies the unit to be used.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 0 ; 2 0 3.5 0 ; 3 6 3.5 0</td>
</tr>
<tr>
<td>4 6 0 0 ; 5 6 0 6 ; 6 6 3.5 6</td>
</tr>
</tbody>
</table>

Joint number followed by X, Y and Z coordinates are provided above. Semicolon signs (;) are used as line separators. That enables you to provide multiple sets of data on one line.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 2 ; 2 2 3 ; 3 3 4</td>
</tr>
<tr>
<td>4 5 6 ; 5 6 3</td>
</tr>
</tbody>
</table>

Defines the members by the joints they are connected to.

<table>
<thead>
<tr>
<th>UNIT MMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMBER PROPERTY AMERICAN</td>
</tr>
<tr>
<td>1 4 PRIS YD 300 ZD 275</td>
</tr>
<tr>
<td>2 5 PRIS YD 350 ZD 275</td>
</tr>
<tr>
<td>3 PRIS YD 350</td>
</tr>
</tbody>
</table>

Member properties have been defined above using the PRISMATIC attribute for which YD (depth) and ZD (width) values are provided in MM unit. When YD and ZD are provided together, STAAD considers the section to be rectangular. When YD alone is specified, the section is considered to be circular. Details are available in Section 5 of the Technical Reference Manual.

<table>
<thead>
<tr>
<th>CONSTANTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>E 22 MEMB 1 TO 5</td>
</tr>
</tbody>
</table>

Material constant E (modulus of elasticity) is specified as 22KN/sq.mm following the command CONSTANTS.

<table>
<thead>
<tr>
<th>UNIT METER KN</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTANTS</td>
</tr>
<tr>
<td>DENSITY 25.0 ALL</td>
</tr>
<tr>
<td>POISSON 0.17 ALL</td>
</tr>
</tbody>
</table>

Length unit is changed from MMS to METER to facilitate the input of Density. Next, the Poisson’s Ratio is specified.

<table>
<thead>
<tr>
<th>BETA 90 MEMB 4</th>
</tr>
</thead>
</table>

In the absence of any explicit instructions, STAAD will orient the beams and columns of the structure in a predefined way (see Section 1 of the Technical Reference Manual for details.) In order to orient member 4 so that its longer edges (sides parallel to local Y axis) are parallel to the global Z axis, you must apply a beta angle of 90 degrees.

<table>
<thead>
<tr>
<th>SUPPORT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 4 5 FIXED</td>
</tr>
</tbody>
</table>

Joints 1, 4 and 5 are defined as fixed supported.

<table>
<thead>
<tr>
<th>UNIT METER KG</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOAD 1 DEAD LOAD</td>
</tr>
</tbody>
</table>

Force units are changed from KN to KG to facilitate the input of loads. Load case 1 is initiated along with an accompanying title.

| SELFWEIGHT Y -1 |
One of the components of load case 1 is the selfweight of the structure acting in the global Y direction with a factor of -1.0. Since global Y is vertically upward, the factor of -1.0 indicates that this load will act downwards.

```
MEMBER LOAD
2 5 UNI
GY -400
```

Load 1 contains member loads also. GY indicates that the load is in the global Y direction. The word UNI stands for uniformly distributed load. Loads are applied on members 2 and 5.

```
LOAD 2 LIVE LOAD
```

Load case 2 is initiated along with an accompanying title.

```
MEMBER LOAD
2 5 UNI
GY -600
```

Load 2 also contains member loads. GY indicates that the load is in the global Y direction. The word UNI stands for uniformly distributed load. Loads are applied on members 2 and 5.

```
LOAD 3 WIND LOAD
```

Load case 3 is initiated along with an accompanying title.

```
MEMBER LOAD
1 UNI
GX 300
4 UNI
GX 500
```

Load 3 also contains member loads. GX indicates that the load is in the global X direction. The word UNI stands for uniformly distributed load. Loads are applied on members 1 and 4.

```
LOAD 4 DEAD + LIVE
```

Load case 4 is initiated along with an accompanying title.

```
REPEAT LOAD
1 1.2 2 1.5
```

Load case 4 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases specified earlier. This repeat load case instructs the program to analyze the structure for loads from cases 1 and 2 acting simultaneously. The load data values from load case 1 are multiplied by a factor of 1.2, and the resulting values are utilized in load case 4. Similarly, the load data values from load case 2 are multiplied by a factor of 1.5, and the resulting values too are utilized in load case 4.

```
LOAD 5 DEAD + WIND
```

Load case 5 is initiated along with an accompanying title.

```
REPEAT LOAD
1 1.1 3 1.3
```

This repeat load case instructs the program to analyze the structure for loads from cases 1 and 3 acting simultaneously.

```
PDELTA ANALYSIS
```

The PDELTA ANALYSIS command is an instruction to the program to execute a second-order analysis and account for P-delta effects.

```
LOAD LIST 4 5
```
The above LOAD LIST command is a means of stating that all further calculations should be based on the results of load cases 4 and 5 only. The intent here is to restrict concrete design calculations to that for load cases 4 and 5 only.

```
START CONCRETE DESIGN
CODE ACI
UNIT MMS
NEWTON
CLT 25 ALL
CLB 30 ALL
CLS 25 ALL
FC 25 ALL
FYMAIN 415 ALL
TRACK 1 ALL
```

The first line is the command that initiates the concrete design operation. The values for the concrete design parameters are defined in the above commands. Design is performed per the ACI Code. The length units are changed from METER to MMS to facilitate the input of the design parameters. Similarly, force units are changed from KG to NEWTON. The TRACK value dictates the extent of design related information which should be produced by the program in the output. The parameters specified include CLT (Clear cover for top surface), CLB (Clear cover for bottom surface), CLS (Clear cover for sides), FC(Strength of concrete), and FYMAIN (Ultimate strength of steel). These parameters are described in Section 3 of the Technical Reference Manual.

```
DESIGN BEAM 2 5
DESIGN COLUMN 1 3 4
```

The above commands instruct the program to design beams 2 and 5 for flexure, shear and torsion, and to design columns 1, 3 and 4 for axial load and biaxial bending.

```
END CONCRETE DESIGN
```

This command terminates the concrete design operation.

```
FINISH
```

This command terminates the STAAD run.

**Save** the input file and close the editor. The model is opened in the STAAD.Pro interface.

### T.2 Performing the analysis and design

STAAD.Pro performs Analysis and Design simultaneously.

1. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group.

   ![Run Analysis tool](image.png)

   As the analysis progresses, several messages appear on the screen as shown in the figure below.
2. Select the View Output File option once the analysis and design are complete.

The three options are indicative of what will happen after you click Done.

**View Output File**
This option opens the output file created by STAAD. The output file contains the numerical results produced in response to the various input commands specified during the model generation process. It also provides you with important messages of any errors that were encountered, and if so, whether the analysis and design was successfully completed or not. See T.1 Viewing the output file (on page 433) for details on viewing and understanding the contents of the output file.

**Go to Post Processing Mode**
This option opens the graphical Post-processor mode, which can be used to extensively review and verify the results. This mode allows you to view the results graphically, plot result diagrams, produce reports, etc. See T.1 Post-Processing (on page 441) for details on the Post processing mode.

**Stay in Modeling Mode**
This option closes the dialog and remains in the Model generation mode of the program, where you initiated the analysis. This is useful if you want to make further changes to the input file.

3. Click Done. The STAAD.Pro Output Viewer window opens.
T.2 Viewing the output file

During the analysis process, STAAD.Pro creates an Output file. This file provides important information on whether the analysis was performed properly.

For example, if STAAD.Pro encounters an instability problem during the analysis process, it will be reported in the output file.

**Note:**
If you did not select to open the output file after running the analysis in the previous procedure, you can open it any time through the user interface. On the Utilities ribbon tab, select the Analysis Output tool in the View group.

**Tip:** By default, the output file contains a listing of the entire input also. You may choose not to print the echo of the input commands in the Output file. On the Analysis and Design ribbon tab, select the Miscellaneous Commands > Set Echo tool option from the menu bar and the select the Echo Off option in the Set Echo dialog.

It is *strongly recommended* that you review the entire output file to ensure that the results are reasonable and that there are no error messages or warnings reported, etc. Errors encountered during the analysis & design can disable access to the post-processing mode. The information presented in the output file is a crucial indicator of whether or not the structure satisfies the engineering requirements of safety and serviceability.

T.2 Post-Processing

STAAD.Pro offers extensive result verification and visualization facilities. These facilities are accessed from the Post Processing Mode. The Post Processing mode is used to verify the analysis and design results and generate reports.

T.2 Opening the postprocessing workflow

You can open the Postprocessing workflow anytime there are current analysis results for your model.

If you selected to open the postprocessing mode after T.2 Performing the analysis and design (on page 499), then you can skip to step 2.

1. On the Workflows panel, select Postprocessing.

The Results Setup dialog opens.
2. (Optional) Select the load cases for which to display the results.

**Tip:** All load cases are selected by default.

For this tutorial, we will use all load cases.

### T.2 Viewing the deflection diagram

1. Select the **Displacement** page in **Postprocessing** page control bar.

**Tip:** This page is the default page when you open the Postprocessing workflow.

**Note:** You can display the Deflection diagram on most results pages by selecting the **Deflection** tool. The tool remains depressed when the displacement is displayed.

The displacement diagram is drawn on the structure. The **Node Displacements table** and **Beam Relative Displacement Detail** table open. See **T.2 The Node Displacements Table** (on page 512) for details on these tables.

2. (Optional) If the deflection is not exaggerated enough to clearly identify, you can change the scale:
   a. On the Results ribbon tab, select the **Scale** tool in the **Configuration** group.

The **Diagrams** dialog opens displaying the **Scales** tab.
Tip: You can also open the **Diagrams** dialog by selecting the **Structure** tool or by right-clicking in the View area and then selecting **Structure Diagrams** from the pop-up menu.

b. Change the **Displacement** value.

**Tip:** Smaller numbers exaggerate the deflected shape.

Type a value of 5 (mm per m) to clearly see the deflection due to load case 5.

c. Click **Apply**.

**Tip:** You can set the **Apply Immediately** option on this tab to view the scale change as you use the up/down arrows in the Displacement field.

d. Click **OK**.

3. To change the load case being displayed, select from the current **Load** list in the window status bar.

```
Tip: Alternatively, select the **Structure** tool ![Structure Tool] in the **Configuration** group on the **Results** toolbar. The active load case can be selected on the **Load and Results** tab in the **Diagrams** dialog.
```

The results displayed are for the selected load case only.

Select **5: DEAD + WIND** for this tutorial.
4. Annotate the deflection at specific nodes:
   a. On the Results ribbon tab, select the **Annotate** tool in the **Configuration** group.

   The **Annotation** dialog opens.

   b. On the **Ranges** tab, select the **Ranges** option and then type 2 3 6 (spaced node number list) in the **Nodes** field.
c. Select the **Node** tab and then check the **Resultant** option.

Resultant stands for the square root of sum of squares of values of X, Y and Z displacements.

d. Click **Annotate** and then click **Close**.

The structure deflection diagram is annotated for load case 5, as in the following figure.
5. Change the display units for displacement:

   The units in which displacement values are displayed in the post-processing mode are referred to as the display units.

   a. On the File ribbon tab, select Display Options on the Settings tab.

      The Options dialog opens.

   b. Select the Structure Units tab.

   c. Change Displacement selection from mm (millimeter) to cm (centimeter).
d. Click OK. The diagram will be updated to reflect the new units.

T.2 The Node Displacements Table

When the Displacements page is selected, two tables open on the right side of the program window.

The Node Displacements table lists the displacement values for every node for every selected load case. The Beam Relative Displacement Detail table displays the displacements along beams at intermediate points.

Note: The load cases included in results tables can be restricted using the Results Setup dialog. Refer to T.2 Restricting the load cases for results (on page 522) for details.

Tip:
You can reopen any closed tables from the Tables dialog, which is opened by selecting the Tables tool in the Windows group on the View ribbon tab.

</table>

*Figure 59:*

**All** This tab presents all nodal displacements in tabular form for all load cases and all degrees of freedom.

**Summary** This tab, shown in the figure below, presents the maximum and minimum nodal displacements (translational and rotational) for each degree of freedom. All nodes and all Load Cases specified during the Results Setup are considered. Maximum values for all degrees of freedom are presented with the corresponding Node of occurrence and Load Case number (L/C).
The Beam Relative Displacement Detail table

![Beam Relative Displacement Detail Table](image)

Figure 60:

**All** tab presents the displacements of members at intermediate section points. All specified members and all specified load cases are included. The table shows displacements along the local axes of the members, as well as their resultants.

**Max Displacements** tab presents the summary of maximum sectional displacements (see figure below). This table includes the maximum displacement values and location of its occurrence along the member, for all specified members and all specified load cases. The table also provides the ratio of the span length of the member to the resultant maximum section displacement of the member.

T.2 Viewing the force and moment diagrams

**Tip:** You can display force or moment diagrams on most any page in the Post-Processing, but is recommended to use the Beam | Forces page to do so.

1. Select the **Beam Results** page on the **Postprocessing** page control bar.

   **Note:** You can display force and moment diagrams on most results pages by selecting corresponding tool from the **View Result** group on the **Results** ribbon tab. The corresponding tool remains depressed when the diagram is displayed.

   The bending moment $M_z$ is drawn on the structure by default. The **Beam End Forces** table and **Beam Force Detail** table open. T.2 The **Beam Forces Table** (on page 519) for details on these tables.

2. To change the force or moment (i.e., degree of freedom) diagram displayed, either:

   - select the corresponding diagram tool from the **View Result** group on the **Results** ribbon tab
   - or

   select **Structure** tool in the **Configuration** group on the **Results** ribbon tab and then select the degrees of freedom to display from the **Beam Forces** group on the **Loads and Results** tab.
Table 22: Results diagram tools

<table>
<thead>

<td>Displays the bending Z diagram</td>
</tr>
<tr>
<td><img src="92x499" alt="Image" /></td>
<td>Displays the beam stress (tension and compression) diagrams.</td>
</tr>
</tbody>
</table>

**Note:** The **Load and Results** tab on the **Diagrams** dialog can also be used to select the color for each diagram as well as the display method (i.e., hatched, filled, or outline).

**Tip:** You can display multiple diagrams simultaneously.

3.  (Optional) If the force or moment diagram is not exaggerated enough to clearly identify, you can change the scale:
   a. On the Results ribbon tab, select the **Scale** tool in the **Configuration** group.

   The **Diagrams** dialog opens displaying the **Scales** tab.

   **Tip:** You can also open the **Diagrams** dialog by selecting the **Structure** tool or by right-clicking in the View area and then selecting **Structure Diagrams** from the pop-up menu.

   b. Change the value in the corresponding **Results Scales** group to the diagram currently displayed.

   **Tip:** Smaller numbers exaggerate the diagram.

   Type a value of 50 (kN/m per m) to clearly see the **Bending Z** due to load case 5.

   c. Click **Apply**.

   **Tip:** You can set the **Apply Immediately** option on this tab to view the scale change as you use the up/down arrows in any of the **Result Scales** fields.

   d. Click **OK**.

4. To change the load case being displayed, select from the current **Load** list in the window status bar.
Tip: Alternatively, select the **Structure** tool in the **Configuration** group on the **Results** toolbar. The active load case can be selected on the **Load and Results** tab in the **Diagrams** dialog.

The results displayed are for the selected load case only.

5. Annotate the bending Z moment diagram to display the maximum moment in the beams for load case 5:
   a. Select **Results > View Value**.
      The **Annotation** dialog opens.
   b. On the **Ranges** tab, select the **Ranges** option and then type 2 5 (spaced node number list) in the **Beams** field.
   c. Select the **Beam Results** tab and then check the **Maximum** option in the **Bending** group.
d. Click **Annotate** and then click **Close**.

The bending Z moment diagram is annotated for load case 5, as in the following figure.

![Bending Z Moment Diagram](image)

*Figure 61:*

6. Change the display units for bending moments:
The units in which results values are displayed in the post-processing mode are referred to as the display units.

a. On the File ribbon tab, select Display Options on the Settings tab.

   The Options dialog opens.

b. Select the Force Units tab.

c. Change Moment selection from kNm (kilonewton meters) to kip-ft (kilopound feet).

d. Click OK.

   The diagram updates to reflect the new units.

T.2 The Beam Forces Table

When the Beam Results page is selected in the Postprocessing workflow, two tables open on the right side of the program window.

The Beam End Forces table lists the axial forces and shear forces, bending and torsional moments in all selected beams for all selected load cases are displayed in a tabular form along the right half of the screen.

The Beam Force Detail table lists force and moment values for every node for every selected load case.

Note: The load cases included in results tables can be restricted using the Results Setup dialog. Refer to T.2 Restricting the load cases for results (on page 522) for details.
Tip:
You can reopen any closed tables from the Tables dialog, which is opened by selecting the Tables tool in the Windows group on the View ribbon tab.

The Beam End Forces table

Figure 62:

All  This tab presents all forces and moments corresponding to all 6 degrees of freedom at the start and end of each selected member for all selected load cases.

Summary  This tab, shown in the next figure, presents the maximum and minimum values (forces and moments) for each degree of freedom. All beams and all Load Cases specified during the Results
Setup are considered. Maximum values for all degrees of freedom are presented with the corresponding Node of occurrence and Load Case number (L/C).

Envelope  This tab shows a table consisting of the maximum and minimum for each degree of freedom for each member, and the load case responsible for each of those values.

T.2 Viewing the force and moment graphs

The Graphs results in the Postprocessing workflow are used to view moment and force graphs such as Axial, Bending zz, Shear yy and Combined Stresses for individual members.

1. Display the beam results graphs:
   a. On the Results ribbon tab, select the Tables tool in the View Results group.
   b. In the Beam Results group, select Graphs.
   The View window shows the loading on the structure. On the right side of the screen, the force/moment diagrams appear.

2. Select a member in the View window.
   The graphs are plotted for that member in the data area.

   Figure 63: Bending, shear, and axial graphs for Beam 2 under load case 5: DEAD + WIND.

3. To change the diagrams displayed for the current beam and load case selection:
   a. Right-click on any graph window and select Diagrams from the pop-up menu.
      The Diagram dialog opens.
   b. Set the check box for the degrees of freedom you wish to view in the diagram.
c. Click OK.
The selected degree of freedom is plotted in that window.

T.2 Restricting the load cases for results
To restrict the load cases for which results are viewed, use the following procedure.

1. On the Results ribbon tab, select the Select Load Case tool in the Configuration group.

![Diagram](image.png)

Figure 64:
The Results Setup dialog opens.
2. Click [<<].
All load cases are moved from the Selected list to the Available list.
3. Select two load cases to use for viewing results:
   a. Press and hold the `<Ctrl>` key and then select load cases 1 DEAD LOAD and 3 WIND LOAD.
   b. Click `[>].`
   c. Click OK.

T.2 Using Member Query

Member query is a facility where several results for specific members can be viewed at the same time from a single dialog. It is also a place from where many of the member attributes such as the property definition, specifications (releases, truss, cable, etc.) and beta angle can be changed for input purposes.

**Note:** The Beam Cursor tool is active when the Beam Results page is selected.

1. Double-click a member in the View window.

   **Tip:** Alternately, if you have selected a member you can then select Tools > Query > Member.

   For this example, double-click on member 4.

   The Beam dialog opens.

   In the Modeling mode, you can actively edit members using this dialog. In the Post-Processing mode, the member data is presented for review only.
**Note**: The tabs in the member query dialog reflect the properties of the member along with any analysis and design results available. Changing the model will void any results and thus remove these tabs until another analysis is performed.

**Figure 66:**

2. Select the **Shear Bending** tab.

Here you can review shear and bending diagrams for the member for a selected load case. A table presents the shear and bending at specific locations along the member length. The slider control can be used to review the values at distance.
3. Select the **Deflection** tab.

Here, a similar diagram of the member deflection is shown for the selected load case. A table displays the deflection values at specific points along the member length.
4. Select the **Concrete Design** tab.

**Note:** This tab is only available for concrete members which have been designed using the concrete design command and after a successful analysis has been performed.
5. (Optional) Click Print

The query results for the current dialog tab are printed using the report output settings. Refer to T.2 Creating Customized Reports (on page 530) for details on the report settings.

6. Click Close.

To review the member query results of another beam, the Beam dialog must be closed. Repeat this procedure for another member to query it.

T.2 Producing an on-screen report

Occasionally, we will come across a need to obtain results conforming to certain restrictions, such as, say, the resultant node displacements for a few selected nodes, for a few selected load cases, sorted in the order from low to high, with the values reported in a tabular form. The facility which enables us to obtain such customized on-screen results is the Report menu on top of the screen.

Here, you will create a report that includes a table with the member major axis moment (MZ) values sorted in the order High to Low, for members 1 and 4 for all the load cases.
1. Press and hold <Ctrl> and click both members 1 and 4 in the View window to select them.

2. On the Results ribbon tab, select the Reports > Beam End Forces tool in the Reports group.

   ![Beam End Force dialog](image)

   The Beam End Force dialog opens.

3. Specify the report contents:
   a. Select the Sorting tab.
   b. Select the Moment-Z option in the Sort By End Force group.
   c. Select List from High to Low option in the Set Sorting Order group.
   d. Check the Absolute Values option in the If Sorting done group.

4. Select the Loading tab and ensure all the five load cases are added to the Selected list.

5. (Optional) You can save this report for future use,
   a. Select the Report tab
   b. Type a Title for the report.
   c. Set the Save Report check box.

6. Click OK.

   The member end forces sorted table opens with the MZ values sorted from High to Low based on Absolute numbers.
T.2 Taking Pictures

To take a screen capture of the View window contents for use generating external reports, use the following procedure.

1. On the Utilities ribbon tab, select the Take Picture tool in the Utilities group.

![Take Picture tool]

The Picture # dialog opens.

![Picture # dialog]

2. (Optional) Type a Picture ID

   The ID is incremented automatically.

3. (Optional) Type a Caption

   **Note:** For most View window contents, the caption will be automatically completed with a description of the contents.

4. Click OK.

   This picture is saved for use in reports.
T.2 Creating Customized Reports

STAAD.Pro offers extensive report generation facilities.

Items which can be incorporated into such reports include input information, numerical results, steel design results, etc. You can choose from among a select set of load cases, mode shapes, structural elements, etc. You can also include any picture of the screen taken using the Take Picture tool. Other customizable parameters include the font size, title block, headers, footers, etc.

1. Open the Report Setup:
   a. Select the File ribbon tab.
      The Backstage view opens.
   b. Select the Report tab and then Setup.
      The Report Setup dialog opens.

   ![Report Setup Dialog]

   **Note:** The Available items list is filtered by the drop-down selection list above it. This allows you to sort your reports.

2. Add model Output to the report:

   **Tip:** Job Information from the Input is selected by default.

   a. Select Output from the drop-down list.
      The Available list displays output items.
   b. Double-click Node Displacement Summary in the Available list.
      This item is added to the Selected list.
c. Double-click **Beam Max Moments** in the Available list.
   This item is added to the Selected list.

d. Select **Pictures** from the drop-down list.
   The Available list displays the picture captured earlier in the tutorial.

e. Double-click **Picture 1**.
   This item is added to the Selected list.

Leave the **Report Detail Increments** at 10. This is the number of segments into which a member is divided for sectional reports (i.e., displacements, forces, etc.).

3. Select the load cases to include in the report as well as how to order the results:
   a. Select the **Load Cases** tab.
   b. If all the load cases are not already included in the output, click [>>].
   c. Select the **by Load Case** option for the **Grouping for Load Tables**.
   d. Select the **by Node/Beam** option for **Grouping for Result Tables**.

![Report Setup](image)

4. (Optional) Select the **Picture Album**

   **Tip:** You can manage pictures taken using the **Take Picture** tool here.
5. Customize the title block of your report with your organization’s information:
   a. Select the **Name and Logo** tab.
   b. Click in the empty text field and type the name and address of your organization.
   c. (Optional) Click **File Graphic**
      
      By default, the Bentley Systems, Inc. logo is used for STAAD.Pro reports.
      
      Logo files must be in Bitmap (file extension .bmp) format.
   d. Click **Font** in the **Text** group.
      
      The Font dialog opens. You can select any Windows font, style, and size. Click OK when done.
6. Click **OK**.

   **Tip:** You can click **Print** to print the report directly from this dialog, but it is recommended to preview the report prior to printing.

7. Select the **File** ribbon tab and then select **Report > Print Preview**.

   The Print Preview window opens with the report contents. Here you can review and print the report. The first and the last pages of the report are shown in the next two figures.
Tutorials
T.2 - RC Framed Structure

Job Information

Structure Type: SPACE FRAME

Number of Nodes: 5
Number of Element: 5
Number of Basic Load Cases: 3
Number of Combination Load Cases: 0

Included in this printout are results for load cases:

8. Click **Close**.

This brings us to the end of this tutorial.

**T.3 - Analysis of a slab**

This tutorial provides step-by-step instructions for modeling and analysis of a slab supported along two edges.
T.3 Methods of creating the model

As explained in T.1 Methods of creating the model (on page 373) in Tutorial 1, there are three methods of creating the structure data:

1. Using the STAAD.Pro Physical Modeler interface (on page 539),
2. using the traditional STAAD.Pro analytical modeling interface (on page 547),
3. and using the command file (on page 587).

All three methods of creating the model are explained in this tutorial. The physical modeling method is explained first, beginning with “T.3 Creating the Model using the Physical Modeler (on page 539),” then the analytical model method is explained beginning with “T.3 Description of the tutorial problem (on page 536).” The command file method is explained in “T.3 Creating the model using the command file (on page 587).”

T.3 Description of the tutorial problem

The structure for this project is a slab fixed along two edges. You will model it using 6 quadrilateral (i.e., 4-noded) plate elements. The structure and the mathematical model are shown in the figures below. It is subjected to selfweight, pressure loads and temperature loads. The purpose of this tutorial to create the model, assign all required input, perform the analysis, and review the results.
Basic Data for the Structure

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element properties</td>
<td>Slab is 300 mm thick</td>
</tr>
</tbody>
</table>
### Attribute | Data
--- | ---
Material Constants | E, Density, Poisson, Alpha — Default values for concrete
Supports | Nodes along 2 adjacent edges; fixed against rotation and translation
Primary Loads | Load 1: Selfweight  
Load 2: Pressure Load of 300 kg/m² acting vertically downwards  
Load 3: 75 degree F uniform expansion, plus top surface is 60 degrees hotter than the bottom
Combination Loads | Case 101: Case 1 + Case 2  
Case 102: Case 1 + Case 3
Analysis Type | Linear Elastic

### T.3 Creating a new structure

On the Start page **New** tab, you will provide some initial data necessary for building the model.

1. On the Start page, select **New**.
   - The **New** page opens to the **Model Info** tab.
2. Type as **Plates Tutorial** in the **File Name** field.
3. Specify a **Location** where the STAAD input file will be located on your computer or network.
   - You can directly type a file path or click **Browse** to open the **Browse by Folder** dialog, which is used to select a location using a Windows file tree.
4. Select **Physical** for the **Type** of model.
   - This option selects the modeling method you want to use:
     - **Analytical** For creating a model using either the STAAD.Pro analytical modeling interface or the command input file editor.
     - **Physical** For creating a model using the STAAD.Pro Physical Modeler interface.
     - **Building** For creating a building model structure using the Building workflow.
5. Select **Metric** as the system of **Units**.
   - **Tip:** The units can be changed later if necessary, at any stage of the model creation.
6. (Optional) Select the **Job Info** tab to enter related project details, names and dates for quality analysis, and ProjectWise Project information.
7. Click **Create**.
The STAAD.Pro modeling environment opens and your model file is then opened in the STAAD.Pro Physical Modeler.

Alternatively, if you want to use either the analytical modeling workflow or the command input file editor to create the model, choose Analytical, click Create, and then proceed to either "T.3 Creating the model using the analytical user interface (on page 547)" or "T.3 Creating the model using the analytical user interface (on page 547)," respectively.

T.3 Creating the Model using the Physical Modeler

You are now ready to start building the model geometry. The steps for doing this are described in the following sections.

Tip: Refer to the STAAD.Pro Physical Modeler Application Window Layout for reference on the application window.

T.3 Generate the model geometry

1. On the Model ribbon tab, select the Grid tool in the Create group.

The Create Grid dialog opens.

2. Supply the grid details:
   a. Type Grid 1 in the Name field.
   b. Select XZ as the Plane.
   c. Leave the Creation Method as By Spacing.
   d. Type 3 in the Number of Spaces in X and 2 m in the Grid spacing X field.
   e. Type 2 in the Number of Spaces in Z and 2 m in the Grid spacing Z field.
   f. Click OK.
      The grid is created.

3. Orient the view from the top:
   a. (Optional) If the rotation controls are hidden, click the rotation widget in the lower-right corner of the view window.
   b. Select the Switch to top view tool.
   c. (Optional) Click the rotation widget again to hide the controls.

   Tip: Alternatively, you can press and hold the right mouse button and drag the mouse pointer to quickly rotate the view so it is easy to select the column bases.

4. On the Model ribbon tab, select the Surface tool in the Create group.
5. Draw the surface:
   a. Click on the grid point at (0,0,0) (i.e., top-left corner).
   b. Click on the grid corners in a counterclockwise order. Double-click on the last point to stop drawing surface vertices.
      (6,0,0)
      (6,0,4)
      (0,0,4)
   c. Select the Surface tool again to deactivate the tool.

6. On the View ribbon tab, select the Local Axis tool in the Model group.

![Local Axis](image)

The local axes are displayed on the center of the surface. Note that local axis x is aligned with the edge defined by the first two nodes.

### T.3 Specifying element and material properties

1. Select the surface element.

2. On the Surface Tools ribbon tab, select the Material tool in the Assign Properties group.

![Assign Material](image)

The Assign material dialog opens.

3. Assign a catalog concrete material:
   a. Select the Source as Catalog.
   b. Select the Type as Standard.
   c. Select the Country as United States.
   d. Select the Material type as CONCRETE_ACI318.
   e. Select 4000 psi from the Material name list.
   f. Click OK

The dialog closes and the material name is displayed on the surface.

![Assign Thickness](image)

The Assign Surface Thickness dialog opens.

5. Type 300 mm in the Thickness field and then click OK.

The dialog closes and the thickness is displayed on the surface.
T.3 Specifying supports

**Tip:** You may want to turn off the display of Loads to make selecting the surface easier. To do so, select the **Loads** tool in the **Toggle Attributes** group on the **View** ribbon tab.

1. Select the surface and the nodes along the “top” edge:
   a. Click in an empty area of the view window to deselect all objects.
   b. Click on the surface to select it.
   c. While holding `<Ctrl>`, drag a rectangular area surrounding nodes N2 and N3.
2. On the **Surface Tools** ribbon tab, select the **Linear** tool in the **Mat and Edge Supports** group.

   The **Assign Custom Linear Support** dialog opens.

3. Specify the support parameters:
   Leave the **Support type** selection as **Restraints**.
   a. Type 3 in the **Segments** field.
   b. Check all the restrained options for X, Y, and Z in both the **Translation** and **Rotation** groups.
   c. Click **OK**.

   A series of blocks are drawn along the edge to indicate the support condition.

4. Repeat steps 1 through 3 but select the “left” edge nodes (N1 and N2) and use 2 segments.
T.3 Specifying load groups 1 and 2

1. On the Spreadsheet ribbon tab, select the Load Cases tool in the References group.

The Load Cases spreadsheet opens.

2. For Load 1:
   a. Type Dead Load in the description field of Load case 1.
   b. Select Dead as the Type.
   c. Type -1 in the Self-weight multiplier in field Y.

   Note: This value is negative.

   d. Press <Enter>. 
3. Create a load group for the external pressure load:
   a. On the Model ribbon tab, select the Load Case tool in the Load group.

   The Add Load Case dialog opens.
   b. Type External Pressure Load in the Name field.
   c. Select Floor Unspecified as the Type.
   d. Click OK.

   The new load group is created and selected as the active load group.

4. On the Surface Tools ribbon tab, select the Pressure tool in the Loads group.

   The Add Surface Uniform Pressure dialog opens.

5. Specify the pressure load:
   a. Type -300 kg/m² in the Pressure field.
   b. Select Global Y as the Direction.

   Tip: Since the surface is parallel to the XZ plane, you could also have selected local 3 as to achieve the same direction. However, due to the counterclockwise selection of nodes, the local 3 axis is oriented in the opposite direction of the Global Y. Therefore, you would use a positive magnitude for that case.
   c. Click OK.

   The temperature load must be added directly to the analytical model in the STAAD.Pro interface. This is done after you generate the analytical model.

T.3 Generate the Analysis Model

You have now completed the majority of the modeling portion of this tutorial. You will now send the model data back to STAAD.Pro where you will add the final load case, create load combinations, add output commands, select analysis criteria, and specify post-processing print commands.

1. Change the mesh size:
a. Select the **File** ribbon tab. 
The backstage view opens.

b. Select the **Options** tab. 
The **Options** dialog opens.

c. Select the **Analysis model** tab.

d. Type 2.0 m in the **Maximum allowed distance between nodes** field.

e. Click **OK**.

2. Either:

On the **Model** ribbon tab, select the **Return to Analytical Modeling** tool in the **STAAD.Pro** group

![Image of the Return to Analytical Modeling dialog]

or

On the **File** ribbon tab, select **Create analysis model** in the backstage tabs
The Return to Analytical Modeling dialog opens and displays the progress of the analytical model being generated.

T.3 Create primary load cases

1. In STAAD.Pro, select the **Loading** page in the **Analytical Modeling** page control bar.

   The **Loading** ribbon tab is selected and the **Load & Definition** dialog opens.

2. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group.

   ![Image of the Add New: Load Cases dialog]

   The **Add New: Load Cases** dialog opens.
3. Create a pair of primary load cases:
   a. Type Dead Load as the Title for Load Case 1.
      Leave the Number as the default (1) and leave the Loading Type as None.
   b. Click Add.
      Note that the dialog stays open but the load case number is automatically incremented.
   c. Type External Pressure Load as the Title.
      Again, it is not necessary to select a Loading Type.
   d. Click Add.
   e. Click Close.

4. Assign the reference loads to the primary load cases:
   a. On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.

   The Add New Load Items dialog opens.
   b. Select the Repeat Load > Reference Load tab on the left.
   c. Select R1: "Load group 1" in the Available Load Cases list.
   d. Click >.
      The reference load case is added to the selected loads list.
   e. Click Add.
   f. Click Close.
      The reference load case is now added included in the primary load case for analysis.

5. In the window status bar, select 2: External Pressure Load as the current load case.
6. Repeat Step 4 to add the reference load for Load group 2 to the External Pressure Load primary load case.
**T.3 Add temperature load case**

1. Create a primary load case titled **Temperature Load** and then select it in the status bar.
   a. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group. 

   The **Add New Load Cases** dialog opens.

   b. Type **Temperature Load** as the **Title**.
   
   There are no load combinations used in this model, so you can leave the Loading Type as None.

   c. Click **Add**.

   d. Click **Close**.

2. In the program status bar, select **3: Temperature Load** as the current load case.

3. To generate and assign the third load type:
   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   The **Add New Load Items** dialog opens.

   b. Select the **Temperature** option under the **Temperature Loads** item.

   c. Type **40** in the **Temperature Change for Axial Elongation** field.

   d. Type **30** in the **Temperature Differential from Top to Bottom** field.

   Leave the **Temperature Differential from Side to Side (Local Z)** field as **0** (default).

   e. Click **Add** and then click **Close**.
4. Assign the temperature load case to all of the elements:
   a. In the Load & Definition dialog, select TEMP 40 30.
      This is the input command for the temperature load.
   b. Select the Assign to View option.
   c. Click Assign.
      A message dialog opens confirming you want to make this assignment.
   d. Click Yes.

T.3 Creating the model using the analytical user interface

The following procedures describe how to use the traditional STAAD.Pro analytical user interface to build the model. The steps and, wherever possible, the corresponding STAAD.Pro commands (the instructions which get written in the STAAD input file) are described in the following sections.

**Tip:** Refer to GS. Application Window Layout (on page 50) for reference on the application window.

T.3 Generating the model geometry

The structure geometry consists of joint numbers, their coordinates, member numbers, the member connectivity information, plate element numbers, etc.
The STAAD input file commands generated are:

```
JOINT  COORDINATES
1 0 0 0 ; 2 2 0 0 ; 3 2 0 2 ; 4 0 0 2
5 4 0 0 ; 6 4 0 2 ; 7 6 0 0 ; 8 6 0 2
9 2 0 4 ; 10 0 0 4 ; 11 4 0 4 ; 12 6 0 4
ELEMENT  INCIDENCES  SHELL
1 1 2 3 4 ; 2 2 5 6 3 ; 3 5 7 8 6
4 4 3 9 10 ; 5 3 6 11 9 ; 6 6 8 12 11
```

In this tutorial, you will optionally explore four different methods to create the model:

**T.3 Creating the Plates - Method 1**

To create the plate elements for the slab using a mixture of drawing an element and the Copy/Paste facility, do the following steps.

**T.3 Setup the Grid**

1. On the **Geometry** ribbon tab, select the **Snap Grid/Plate (Quad)** tool in the **Structure** group.
   ![Structure Wizard](image)

   The **Snap Node/Beam** dialog closes and the **Snap Node/Plate** dialog opens.

2. On the **Snap Node/Plate** dialog, click **Create**.
   A dialog opens which will enable us to set up a grid.
   Within this dialog, there is a drop-down list from which you can select Linear, Radial, or Irregular form of grid lines.

   - **Linear** used to place the construction lines perpendicular to one another along a "left to right - top to bottom" pattern, as in the lines of a chess board
   - **Radial** used to place construction lines to appear in a spider-web style, which makes it is easy to create circular type models where members are modeled as piece-wise linear straight line segments
   - **Irregular** used to create gridlines with unequal spacing that lie on the global planes or on an inclined plane

3. Select **Linear**, which is the Default Grid.
   In our structure, the segment consisting of members 1 to 3, and nodes 1 to 4, happens to lie in the X-Y plane.
   So, in this dialog, let us keep **X-Y** as the **Plane** of the grid. The size of the model that can be drawn at any time is controlled by the number of **Construction Lines** to the left and right of the origin of axes, and the **Spacing** between adjacent construction lines.

4. Type a **Name** of **Grid 1**.
5. Select X-Z as the Plane option.
6. Type 6 as the number of lines to the Right of the origin along X and 4 above the origin along Z.
   Leave the spacing as 1 m.
7. Click OK.
8. In the Snap Node/Beam grids list, check the new Grid 1 option.
   You can create any number of grids. By providing a name, each new grid can be identified for future reference.
   
   **Tip:** Please note that these settings are only used to generated construction lines. These construction lines enable you to easily draw the structure but do not restrict our overall model to those limits.

   **Tip:** To change the settings of this grid, select the name in the Snap Node/Beam dialog and then click Edit.

   The check by Default Grid is automatically cleared. STAAD.Pro will only display a single grid at a time.
**T.3 Create Plates Method 1 Element 1**

1. In the View window, click at the origin (0, 0) to create the first node. A line is “rubber-banded” between this node and the mouse pointer, which previews the edge of the plate to be placed with the next mouse click.
2. Click on the following points to create nodes and automatically join successive nodes by beam members.

(2, 0, 0)
(2, 0, 2)
(0, 0, 2)

3. Click **Close** in the **Snap Node/Plate** dialog.

4. Press **<Shift+P>** to display the plate number.
It is very important that we save our work often, to avoid loss of data and protect our investment of time and effort against power interruptions, system problems, or other unforeseen events.

**Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing `<CTRL+S>`.

**T.3 Create Plates Method 1 Element 2**

Creating Elements by Coping and Pasting

Examining the structure shown in “**T.3 Description of the tutorial problem** (on page 536)” of this tutorial, it can be seen that the remaining elements can be easily generated copying the existing plate and then pasting the copied element at specific distances.

1. On the **Geometry** ribbon tab, select the **Plates Cursor** tool in the **Selection** group.

2. Select plate 1 in the View window.

3. Either:
   - Right-click and select **Copy** from the pop-up menu
   - or
   - on the **Geometry** ribbon tab, select the **Copy** tool in the **Clipboard** group
   - or
   - press `<Ctrl+C>`
4. To paste the copied plate element, either:
   Right-click and select **Paste** from the pop-up menu
   or
   on the **Geometry** ribbon tab, select the **Paste** tool in the **Clipboard** group
   or
   press <Ctrl+V>
   The **Paste with Move** dialog opens.

5. Select the **By the following X, Y and Z values** option and then type 2 (m) in the X field.
   Leave the Y and Z values as 0.
6. Click **OK**.
   The dialog closes and the plate is copied to Plate 2 at the specified X axis increment.
7. Repeat steps 4 through 6 except with an X of 4 (m) to create plate 3 from plate 1.

You have now created one half of the symmetric set of plates. You can now copy and paste all three plates to complete the structure.

8. To select all plates, either:
   click-and-drag a window around all three plates using the **Plates Cursor** tool
   or
   press **<Ctrl+A>**
   or
on the Geometry ribbon tab, select the Plates Cursor > All Plates tool in the Selection group.

9. Repeat steps 3 through 6 to copy and paste all the plates, except with a Z of 2 m (leave the X and Y values as 0).

10. Click anywhere in away from the plates to deselect them.

T.3 Create Plates Delete to Try Another Method

If you want to explore the remaining methods of creating this model, the current structure will have to be entirely deleted.

1. To select all plates, either:
   - click-and-drag a window around all three plates using the Plates Cursor tool
   - or
   - press <Ctrl+A>
   - or
   - on the Geometry ribbon tab, select the Plates Cursor > All Plates tool in the Selection group.

2. Either:
   - press <Delete>
   - or
   - on the Plate Tools ribbon tab, select the Delete tool in the Clipboard group
   
   A message dialog opens to confirm the deletion of the selected plates.

3. Click OK
   A message dialog opens indicating that orphan nodes have been created and to confirm their deletion.

4. Click Yes.
   The entire structure is now deleted.
T.3 Creating the Plates - Method 2

To create the plate elements using a mixture of drawing an element and the Translational Repeat facility, use the following steps.

**T.3 Method 2 Creating Element 1**

In this method, you will use the Translational Repeat feature in STAAD.Pro to create the model. First, you need at least one existing entity to use as the basis for the translational repeat.

This method uses the same drawing grid from Method 1. Refer to “T.3 Setup the Grid (on page 548).”

1. In the View window, click at the origin (0, 0) to create the first node.
   A line is “rubber-banded” between this node and the mouse pointer, which previews the edge of the plate to placed with the next mouse click.

2. Click on the following points to create nodes and automatically join successive nodes by beam members.
   
   (2, 0, 0)
   (2, 0, 2)
   (0, 0, 2)
3. Click Close in the Snap Node/Beam dialog.
   The grid is hidden.
4. Press <Shift+P> to display the plate number.

**T.3 Method 2 Creating Elements 2 3**

In Method 1, it required two separate executions of the Copy/Paste function to create elements 2 and 3. That is because, that feature does not contain a provision for specifying the number of copies you want to create. However, with Translational Repeat you can specify the number of copies and distances to each.

1. On the Geometry ribbon tab, select the Plates Cursor tool in the Selection group.

2. Select plate 1 in the View window.
3. On the Geometry ribbon tab, select the Translational Repeat tool in the Structure group.

The Translational Repeat dialog opens.
4. Specify the translation repeat parameters:
   a. Select X as the **Global Direction** option.
   b. Type 2 (m) in the **Default Step Spacing** field.
   c. Type 2 in the **No of Steps** field and press the Tab key (or click the up arrow to increment the value to 2).

   The Step and Spacing table updates to reflect two steps each at 2m spacing.

   Leave the **Renumber Bay** and **Link Steps** options unchecked and the **Generation Flags** set to **All**.

**Note:**

Using the **All** option for Generation Flags (default), all loads, properties, design parameters, member releases, etc. on the selected entities will automatically be copied along with the entities. You can limit this to geometry only or to geometry and properties only. In our example, it does not matter because no other attributes have been assigned yet.

**Renumber Bay** is used to specify a custom number scheme for created entities, instead of the sequential number that the program otherwise generates. The **Linked Steps** option is used to generate linking members between new entities that have some distance separating them from the original entities.

5. Click **OK**

Elements 2 and 3 are created using the translational repeat parameters.
6. To select all plates, either:
   click-and-drag a window around all three plates using the Plates Cursor tool
   or
   press <Ctrl+A>
   or
   on the Geometry ribbon tab, select the Plates Cursor > All Plates tool in the Selection group.

7. Repeat steps 3 and 4 except select Z as the Global Direction and the No of Steps as 1.
   Tip: Be sure to type 2 (m) in the Default Step Spacing field

8. Click anywhere in away from the plates to deselect them.
T.3 Creating the Plates - Method 3

To create the plate elements using the **Structure Wizard** program, use the following steps.

A program installed with STAAD.Pro called **Structure Wizard** offers a library of pre-defined structure templates (also referred to as “prototypes”), such as Pratt Truss, Northlight Truss, Cylindrical Frame, etc. A surface entity such as a slab or wall, which can be defined using 3-noded or 4-noded plate elements, is one such template. You can also create your own library of structure prototypes. From this wizard, a structural model may parametrically be generated, and can then be incorporated into your main structure.

1. On the **Geometry** ribbon tab, select the **Structure Wizard** tool in the **Structure** group.

The **Structure Wizard** window opens.

![Structure Wizard window](image)

*Figure 81: The Structure Wizard window*

**Tip:** The **Open Structure Wizard** option in the **Where do you want to go?** dialog in the beginning stage of creating a new structure also opens this application.

2. The unit of length should be specified prior to the generation of a model.
   a. Select **File > Select Units** in the Structure Wizard window.

   The **Select Units** dialog opens.
b. Select **Meters**.
c. Click **OK**.

3. From the **Model Type** drop-down list, select **Surface/Plate Models**.

4. Either:
   - double-click on the **Quad Plate** option
   - drag the **Quad Plate** option to the right side of the **Structure Wizard** window

   The Select Meshing Parameters dialog opens.
5. Specify the meshing boundary corners and the individual element data as follows:

   a. Enter the following **Corners** data:

<table>
<thead>
<tr>
<th>Corner</th>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>B</td>
<td>6</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>C</td>
<td>6</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>D</td>
<td>0</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

   The Length values are automatically calculated.

   b. Type 3 and the **Divisions** along AB and CD sides and 2 for the **Divisions** along BC and DA sides.

   Leave the **Bias** values all as 1.

   c. Click **Apply**.

   The mesh is generated.

   **Tip:** If you made a mistake, right-click in the drawing area and select **Change Property** from the pop-up menu. The dialog opens and you can edit the mesh generations parameters.
6. Select **File > Merge Model with STAAD.Pro Model.**
   You are prompted to confirm that you want to transfer the model data with your STAAD.Pro model.

7. Click **Yes.**

   The **Paste with Move** dialog opens.

8. Click **OK.**

   In this tutorial, there is no existing model nor is there a need to shift the model from the origin.

   The model will now be transferred to the main window.

   ![Plates Tutorial.std - Whole Structure](image)

   If you want to proceed with assigning the remainder of the data, go to "[T.3 Changing the input units of length](#)" (on page 566).

---

### T.3 Creating the Plates - Method 4

To create the plates using the Mesh Generation facility, use the following steps.

This method uses the same drawing grid from Method 1. Refer to "[T.3 Setup the Grid](#)" (on page 548)."

The STAAD.Pro GUI contains a facility for generating a mesh of elements from a boundary (or superelement) defined by a set of corner nodes. The boundary must form a closed surface and must lie within a plane, though that plane can be inclined to any of the global planes.

You define the boundary by selecting the corner nodes. If these nodes do not exist, they must be created before they can be selected.

1. Create the nodes:
   a. On the **Snap Node/Plate** dialog, click **Snap Node/Plate.**
   b. Click at the four corners of the grid at \((0, 0, 0)\), \((6, 0, 0)\), \((6, 0, 4)\), and \((0, 0, 4)\).

   **Tip:** If the node points are not visible, press `<SHIFT+K>`.

2. In the **Snap Node/Plate** dialog, click **Close.**
3. Use the Plates Cursor and select this plate.
4. To start a quadrilateral mesh of the existing plate element:
a. On the Plate Tools dialog, select the Generate Plate Mesh tool in the Model group.

The Chose Meshing Type dialog opens.

b. Select the Quadrilateral Meshing option.

c. Click OK

The Select Meshing Parameters dialog opens.

5. Complete the meshing parameters:
   a. Type 3 and the Divisions along AB and CD sides and 2 for the Divisions along BC and DA sides.
   b. Click Apply.

The surface is meshed.

6. Re-number the plate elements:
   a. On the Plate Tools ribbon tab, select the Renumber Plates tool in the Model group.
A warning message opens.

**b. Click Yes.**

The **Renumber** dialog opens.

![Renumber Dialog](image)

- **c. Double-click Z Coordinate** in the **Available Sort Criteria** list.
- **d. Double-click X Coordinate** in the **Available Sort Criteria** list.

The Z coordinate entry should appear *above* the X coordinate entry in the **Selected Sort Criteria** list.

- **e. Click Accept.**

The six plates are re-numbered as shown below.

![Plates Tutorial](image)

As an alternative in step 1, you can press and hold `<Ctrl>` to create only disconnected nodes. Then, when you can use the **Generate Mesh > Generate Plate Mesh** tool in the **Plate** group on the **Geometry** ribbon tab to generate the plates from those nodes, rather than re-meshing an existing plate. You then use the plate bound selection cursor ![cursor](image) to select these corner nodes to define a meshed boundary.
**Tip:** Pressing the `<Ctrl>` key while clicking on grid points creates new nodes without connecting those nodes with beams or plates. If the `<Ctrl>` key is not kept pressed, the nodes become connected.

### T.3 Changing the input units of length

To specify element properties for the structure, it is more convenient to use length units of centimeter instead of meter. This requires changing the current length units of input.

The STAAD input file commands generated are:

```
UNIT CM KN
```

1. On the **Geometry** ribbon tab, select the **Input Units** tool in the **Structure** group.

   The **Set Input Units** pop-up opens.

   ![Set Input Units](image)

2. Select **Metric** as the **Input Units**.
3. Set the **Length** units to **Centimeter**.
   - Leave the Force units as KiloNewton.
4. Click **Apply**.

### T.3 Specifying Element Properties

Just as properties are assigned to members, properties must be assigned to plate elements too. The property required for plates is the plate thickness (or the thickness at each node of elements if the slab has a varying thickness).

The STAAD input file commands generated are:

```
ELEMENT PROPERTY
1 TO 6 THICKNESS 30
```
1. To select all plates, either:
   
   click-and-drag a window around all three plates using the **Plates Cursor** tool
   
   or
   
   press **<Ctrl+A>**
   
   or
   
   on the **Geometry** ribbon tab, select the **Plates Cursor > All Plates** tool in the **Selection** group.

2. On the **Specification** ribbon tab, select the **Plate Thickness** tool in the **Plate Profiles** group.

The **Properties - Whole Structure** and the **Plate Element/ Surface Property** dialogs open.
3. Specify the material and thickness:
   a. Type 30 cm for the **Plate Element Thickness** at each corner.
      
      **Tip:** Typing a value in the first field will automatically populate the remaining fields as a uniform thickness is typical.

   b. Ensure that **Material** option is checked and that **CONCRETE** is selected.
      
      This instructs the program to assign the material properties of Concrete (E, Poisson, Density, Alpha, etc.) will be assigned along with the plate thickness.
      
      **Tip:** The material property values so assigned will be the program defaults. You can review those values by clicking **Materials** in the **Properties - Whole Structure** dialog.

   c. Click **Assign**.
   d. Click **Close**.

   The plate property is added to the **Properties - Whole Structure** dialog list and is assigned to the plate elements.
4. Click anywhere in the drawing area to deselect the selected entities.

**Tip:** This is a best practice to follow when using the assignment feature. When an entity is highlighted, clicking on any Assign option is liable to cause an undesired attribute to be assigned to that entity.

**T.3 Specifying Material Constants**

When “T.3 Specifying Element Properties” (on page 566), you used the **Material** option. Consequently, the material definition (E, Density, Poisson’s Ratio, etc.) of concrete were assigned to the plates along with the properties

The STAAD input file commands generated are:

```
DEFINE MATERIAL START
ISOTROPIC CONCRETE
E 2171.85
POISSON 0.17
DENSITY 2.35616e-005
ALPHA 1e-005
DAMP 0.05
TYPE CONCRETE
STRENGTH FCU 2.7579
END DEFINE MATERIAL
CONSTANTS
MATERIAL CONCRETE ALL
```
**T.3 Specifying Supports**

The slab is fixed-supported along the entire length of two adjacent sides. However, when modeled as plate elements, the supports can be specified only at the nodes along those edges, and not at any point between the nodes.

**Tip:** The finer the mesh (i.e., the larger the number of elements), then the more supported nodes you would be able to model. For this tutorial, the 2 meter mesh is used as a simple demonstration.

The STAAD input file commands generated are:

```
SUPPORTS
1 2 4 5 7 10 FIXED
```

**Note:** The node numbers may be different depending on the method of plate creation used. Regardless, the nodes should be those along the X and Z axis.

1. Press `<Shift+N>` to turn on the display of the **Node Numbers**.
   
   This will assist in the identification of the nodes used as supports.

2. On the **Geometry** ribbon tab, select the **Nodes Cursor** tool in the **Selection** group.

3. While pressing the `<Ctrl>` key, select the nodes on two adjacent edges of the plate group:
   
   These nodes are fixed supports in the model.
   
   For example, in the following figure these nodes are:
   
   1
   7
   4
   5
   8
   2
4. On the **Specification** ribbon tab, select the **Fixed** tool in the **Supports** group.

    The Create Support dialog opens with the **Fixed** tab selected.

5. Click **Assign**.
Note: The Assign button is active because you selected the nodes previously.

Figure 85: The structure with fixed supports along two adjacent edges

The fixed support type is also added to the Supports - Whole Structure dialog as S2.

T.3 Specifying Primary Load Cases

Three primary load cases are required for this structure.

The STAAD input file commands generated are:

```
UNIT METER KG
LOAD 1 DEAD LOAD
SELF Y -1.0
LOAD 2 EXTERNAL PRESSURE LOAD
ELEMENT LOAD
1 TO 6 PR GY -300
LOAD 3 TEMPERATURE LOAD
1 TO 6 TEMP 40 30
```

1. Change the units:

   Note: The pressure load value listed in the beginning of this tutorial is in KN and meter units. Rather than convert that value to the current input units, this tutorial will conform to those units. The current input units, which you last set by specifying the thickness was centimeter. Therefore, you need to change the force unit to Kilogram and the length units to Meter.

   a. Click the drop-down arrow beside the current Input Units in the application window status bar. The Set input Units dialog opens.
   b. Select the length units as Meter and the force units as Kilogram.
   c. Click Apply.
2. Add the dead load case:
   a. On the Loading ribbon tab, select the Primary Load Case tool in the Loading Specifications group.

   The Add New Load Cases dialog opens.

   ![Add New Load Cases dialog](image)

   b. Type Dead Load as the Title for Load Case 1.
      Leave the Number as the default (1) and leave the Loading Type as None.

      **Note:** The Loading Type list is used to associate the load case we are creating with any of the ACI, AISC, IBC, or other code-prescribed definitions of Dead, Live, Ice, etc. This type of association needs to be done if you intend to use the program's automatically generating load combinations in accordance with those codes. Note that there is a check box labeled Reducible per UBC/IBC. This feature is active only when the load case is assigned a Loading Type called Live when you create that load case.

   c. Click Add.

   The newly created load case will now appear under the Load Cases Details in the Load & Definition dialog.
3. Create the selfweight load:
   a. On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   The **Add New Load Items** dialog opens.

   ![Add New Load Items dialog](image)

   b. Select the **Selfweight Load** option under the **Selfweight** item.
   c. Select the **Direction** as **Y**
   d. Type the **Factor** as **-1.0**.

   The negative number signifies that the selfweight load acts opposite to the positive direction of the global axis (Y in this case) along which it is applied.

   e. Click **Add**.

4. Assign the selfweight load to all of the elements:
   a. In the **Load & Definition** dialog, select **SELFWEIGHT Y -1**.
   b. Select the **Assign to View** option.
   c. Click **Assign**.

   A message dialog opens confirming you want to make this assignment.

   d. Click **Yes**.

5. Add the pressure load case:
   a. On the **Loading** ribbon tab, select the **Primary Load Case** tool in the **Loading Specifications** group.
The Add New Load Cases dialog opens.

b. Type External Pressure Load as the Title.

Again, there is no need to associate the load case with any code based Loading Type so leave the selection as None.

c. Click Add.

6. On the Loading ribbon tab Display group, select 2: External Pressure Load from the Load drop-down list.

7. Create the pressure load:

   a. On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.

   The Add New Load Items dialog opens.

   b. Select the Pressure on Full Plate option under the Plate Loads item.

   This type enables the load to be applied on the full area of the element.

   Note: The Concentrated Load is for applying a concentrated force on the element. The Trapezoidal and Hydrostatic options are for defining pressures with intensities varying from one point to another. The Partial Plate Pressure Load is useful if the load is to be applied as a “patch” on a small localized portion of an element.

   c. Type -300 kg/m$^2$ in the W1 field (force)

   d. Select GY as the Direction (global Y direction).

   e. Click Add.

   f. Click Close.
8. Repeat steps 5 and 6 to create a third load case titled Temperature Load and then select it on the Loading ribbon tab Display group.

9. To generate and assign the third load type:
   a. On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.

   The Add New Load Items dialog opens.
   b. Select the Temperature option under the Temperature Loads item.
   c. Type 40 in the Temperature Change for Axial Elongation field.
   d. Type 30 in the Temperature Differential from Top to Bottom field.

   Leave the Temperature Differential from Side to Side (Local Z) field as 0 (default).
   e. Click Add and then click Close.
Figure 86:

10. To apply the pressure load and temperature load on all the plates, repeat step 4 for each load item.

Figure 87: The pressure load applied to all plate elements
T.3 Analysis and Design

The following procedures describe how to add analysis and design commands to the STAAD input file.

Note: The analysis design commands are added using either the analytical user interface or the STAAD.Pro Editor. The STAAD.Pro Physical Modeler interface is not used to assign analysis and design commands.

T.3 Creating load combinations

This tutorial requires creating two combination cases.

The STAAD input file commands generated are:

LOAD COMBINATION 101 CASE 1 + CASE 2
1 1.0 2 1.0
LOAD COMBINATION 102 CASE 1 + CASE 3
1 1.0 3 1.0

1. Define load case 4 as a load combination:
   a. On the Loading ribbon tab, select the Combination Load Case tool in the Loading Specifications group.
   
   The Create New Load Combinations dialog opens.
   b. Select the Define Combinations option from the left-hand side.
   c. Type 101 in the Load No: field.
   d. Type Case 1 + Case 2 in the Title field.

   Leave the Type option as Normal and the Default a1 as 1. This uses the algebraic sum of the results for the individual load cases in the load combination. The individual results will have a multiplication factor of 1.
2. Select the load cases for the load combination:
   a. Select 1: DEAD LOAD from Available Load List and then click [>].
   b. Select 2: EXTERNAL PRESSURE LOAD from Available Load List and then click [>].

   Load cases 1 and 2 will appear in the Load Combination Definition list.
   c. Click Add.

   Case 101 is created.

3. To define load case 5 as a load combination, repeat step 1 but type 102 in the Load No: field and type Case 1 + Case 3 in Title field.

4. Repeat step 2 except for selecting load cases 1 and 3 instead of cases 1 and 2.

   **Tip:** The load cases and combination methods used for a load combination can be changed by selecting a load combination and then clicking **Edit**.

   Load 102 is created.

5. Click Close.

   **Tip:** Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing <CTRL + S>.
T.3 Specifying the analysis type

A linear, static analysis is required for this model. You can also instruct STAAD.Pro to provide a static equilibrium report.

The STAAD input file commands generated are:

```
PERFORM ANALYSIS PRINT STATICS CHECK
```

1. On the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group.

The Analysis/Print Commands dialog opens.

Tip: If the Analysis/Print Commands dialog does not open automatically, then click Define Commands in the Analysis - Whole Structure dialog.

2. In the Analysis/Print Commands dialog, select the Perform Analysis tab.
3. Select the **Statics Check** print option.

   **Note:** In response to this option, a report consisting of the summary of applied loading and summary of support reactions, for each load case, will be produced in the STAAD output file.

4. Click **Add**
5. Click **Close**.

   The **Analysis** command is added to the **Analysis - Whole Structure** dialog.
Tip: Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing **<CTRL+S>**.

**T.3 Specifying post-analysis print commands**

Two types of element results can be requested:

a. element stresses at the centroid or any point on the element surface which consist of stresses and moments per unit width, as explained in sections 1.6.1 and 3.41 of the STAAD Technical Reference Manual.

b. the element forces at the nodes which consist of the 3 forces and 3 moments at each node of the elements in the global axis system (see section 3.41 for details).

You will add both types of these results for this tutorial.

You will also need to set the units in which these results are printed to KN and Meter for element stresses and Kg and Meter for element forces.

The STAAD input file commands generated are:

```
UNIT METER KN
PRINT ELEMENT STRESSES LIST 3
UNIT KG METER
PRINT ELEMENT FORCE LIST 6
```

These results will be written in the STAAD output file and can be viewed using the procedure explained in “T.3 Viewing the output file” (on page 591).”

1. Set the length and force units to **Meter** and **Kilonewton** respectively.
   
   Refer to T.3 Changing the input units of length (on page 566) for additional information on this procedure.

2. On the Analysis and Design ribbon tab, select the Post-Analysis Commands tool in the Analysis Data group.

   The Post Analysis Print - Whole Structure dialog opens.

3. On the Post Analysis Print - Whole Structure dialog, click Define Commands.

   The Analysis/Print Commands dialog opens.
4. Select the **Element Forces/Stress** tab.
5. Select the **Print Element Stresses** option.
6. Click **Add** and then click **Close**.
7. Set the length and force units to **Meter** and **Kilogram** respectively.
8. Repeat steps 3 through 6 except select the **Print Element Forces** option in step 5.
Figure 88: The dialog with unassigned commands
9. Associate the print element stresses with element 3:
   a. Select the PRINT ELEMENT STRESSES command in the Post Analysis Print - Whole Structure dialog commands list.
   b. On the Geometry ribbon tab, select the Plates Cursor tool in the Selection group.
   c. In the view window, select element no. 3.
      When you select the plate, the Assignment Method automatically becomes Assign to Selected Plates.
   d. Click Assign.

10. To associate the PRINT ELEMENT FORCE command with element 6, use a similar procedure as step 9 except for selecting element no. 6 in the place of element no. 3.

   Tip: Remember to save your work by either click Save on the File ribbon tab, the Save tool, or pressing <CTRL+S>.

T.3 Viewing the input command file

You can inspect the text data file created during this tutorial.

1. On the Utilities ribbon tab, select the Command File tool in the Edit group.

   The STAAD.Pro Editor opens with the contents of the input file.
2. (Optional) You modify the data of the structure in this editor if necessary.
3. Select **File > Exit Editor** in the STAAD.Pro Editor window to close.

As stated in **Methods of creating the model** (on page 536), you could also have created the same model by typing the relevant STAAD commands into a text file using the STAAD.Pro Editor. If you would like to understand that method, proceed to the next section. If you want to skip that part, proceed to **Performing the analysis and design** (on page 590) where you will perform the analysis and design on this model.

### T.3 Creating the model using the command file

As an alternatively to the procedures described in the proceeding tutorial, you can also create the same STAAD input file using the STAAD.Pro Editor.

**Note:** A STAAD input file is a plain text file that uses the `.std` file extension. Therefore any standard text editor such as Notepad can also be used to create the command file. However, the STAAD.Pro Editor offers the advantage of syntax checking as you type the commands. The STAAD command syntax are highlighted by command, keyword, value, etc.

For this tutorial, delete all the command lines displayed in the editor window and type the lines shown below. While not necessary, this will allow you to learn more about the required and optional command lines for an input file.

STAAD commands are **not** case sensitive (i.e., they may be typed in upper or lower case letters). By convention, this and most input files use all caps, though.
For most all commands and keywords, the first three letters of a keyword are all that are needed. The rest of the letters of the word are not required, but are useful to present a user-friendly command language in mostly plain English for later reference. By convention, the required letters in a command or keyword are underlined here ("PLANE" = "PLA" = "plane" = "pla").

**STAAD SPACE SLAB SUPPORTED ALONG 2 EDGES**

Every input has to start with the word STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

**UNIT METER KN**

Specifies the unit to be used for data to follow.

**JOINT COORDINATES**

1 0 0 0 ; 2 2 0 0 ; 3 2 0 2 ; 4 0 0 2
5 4 0 0 ; 6 4 0 2 ; 7 6 0 0 ; 8 6 0 2
9 2 0 4 ; 10 0 0 4 ; 11 4 0 4 ; 12 6 0 4

Joint number followed by X, Y and Z coordinates are provided above. Semicolon signs (;) are used as line separators. That enables you to provide multiple sets of data on one line. For example, node 6 has (X, Y, Z) coordinates of (4, 0, 2).

**ELEMENT INCIDENCES SHELL**

1 1 2 3 4 ; 2 2 5 6 3 ; 3 5 7 8 6 ; 4 4 3 9 10 ;
5 3 6 11 9 ; 6 6 8 12 11

The incidences of elements are defined above. For example, element 3 is defined as connected between the nodes 5, 7, 8 and 6.

**UNIT CM KN**

**ELEMENT PROPERTY**

1 to 6 THICKNESS 30

The length unit is changed from meter to centimeter. Element properties are then provided by specifying that the elements are 30 cm thick.

**UNIT KN METER**

**CONSTANTS**

E 2.17185e+007 ALL
POISSON 0.17 ALL
DENSITY 23.5616 ALL
ALPHA 1e-005 ALL

Material constants, which are E (modulus of elasticity), Density, Poisson's Ratio and Alpha, are specified following the command CONSTANTS. Prior to this, the input units are changed to Meter and KN.

**SUPPORTS**

1 2 4 5 7 10 FIXED

Joints 1, 2, 4, 5, 7 and 10 are defined as fixed supported. This will cause all 6 degrees of freedom at these nodes to be restrained.

**UNIT KG**

**LOAD 1 DEAD LOAD**

Force units are changed from KN to KG to facilitate the input of loads. Load case 1 is then initiated along with an accompanying title.

**SELFWEIGHT Y -1**
Load case 1 consists of selfweight of the structure acting in the global Y direction with a factor of -1.0. Since global Y is vertically upward, the factor of -1.0 indicates that this load will act downwards.

**LOAD 2 EXTERNAL PRESSURE LOAD**

Load case 2 is initiated along with an accompanying title.

**ELEMENT LOAD**

1 TO 6 PR GY -300

Load 2 is a pressure load on the elements. A uniform pressure of 300Kg/m2 is applied on all the elements. GY indicates that the load is in the global Y direction. The negative sign (-300) indicates that the load acts opposite to the positive direction of global Y.

**LOAD 3 TEMPERATURE LOAD**

Load case 3 is initiated along with an accompanying title.

**TEMPERATURE LOAD**

1 TO 6 TEMP 40 30

Load 3 is a temperature load. All the 6 elements are subjected to a in-plane temperature increase of 40 degrees and a temperature variation across the thickness of 30 degrees. This increase is in the same temperature units as the Alpha value specified earlier under CONSTANTS.

**LOAD COMB 101 CASE 1 + CASE 2**

1 1.0 2 1.0

Load combination 101 is initiated along with an accompanying title. Load cases 1 and 2 are individually factored by a value of 1.0, and the factored values are combined algebraically.

**LOAD COMB 102 CASE 1 + CASE 3**

1 1.0 3 1.0

Load combination 102 is initiated along with an accompanying title. Load cases 1 and 3 are individually factored by a value of 1.0, and the factored values are combined algebraically.

**PERFORM ANALYSIS PRINT STATICS CHECK**

The above command instructs the program to proceed with the analysis. A static equilibrium report is also requested with the help of the words PRINT STATICS CHECK.

**UNIT METER KN**

PRINT ELEMENT STRESS LIST 3

The stresses and unit width moments are requested at the centroid of element 3 in KN and Meter units.

**UNIT KG METER**

PRINT ELEMENT FORCE LIST 6

The forces and moments for all 6 d.o.f at the corner nodes of element 6 are requested in KG and Meter units.

**FINISH**

This command terminates the STAAD run.

Save the input file and close the editor. The model is opened in the STAAD.Pro interface.
T.3 Performing the analysis and design

Tip: Remember to save your work by either click **Save** on the **File** ribbon tab, the **Save** tool, or pressing **<CTRL>+<S>**.

1. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group.

As the analysis progresses, several messages appear on the screen as shown in the figure below.

2. Select the **View Output File** option once the analysis and design are complete.

The three options are indicative of what will happen after you click **Done**.

- **View Output File**: This option opens the output file created by STAAD. The output file contains the numerical results produced in response to the various input commands specified during the analysis.
- **Go to Post Processing Mode**: This mode allows for further examination and analysis of the results.
- **Stay in Modeling Mode**: This option keeps the user in the modeling phase for additional design modifications if needed.
the model generation process. It also provides you with important messages of any errors were encountered, and if so, whether the analysis and design was successfully completed or not. See T.1 Viewing the output file (on page 433) for details on viewing and understanding the contents of the output file.

**Go to Post Processing Mode**

This option opens the graphical Post-processor mode, which can be used to extensively review and verify the results. This mode allows you to view the results graphically, plot result diagrams, produce reports, etc. See T.1 Post-Processing (on page 441) for details on the Post processing mode.

**Stay in Modeling Mode**

This option closes the dialog and remains in the Model generation mode of the program, where you initiated the analysis. This is useful if you want to make further changes to the input file.

3. Click **Done**.
   The STAAD.Pro Output Viewer window opens.

### T.3 Viewing the output file

During the analysis process, STAAD.Pro creates an Output file. This file provides important information on whether the analysis was performed properly.

For example, if STAAD.Pro encounters an instability problem during the analysis process, it will be reported in the output file.

**Note:**

If you did not select to open the output file after running the analysis in the previous procedure, you can open it any time through the user interface. On the **Utilities** ribbon tab, select the **Analysis Output** tool in the **View** group.

**Tip:** By default, the output file contains a listing of the entire input also. You may choose not to print the echo of the input commands in the Output file. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands** > **Set Echo** tool option from the menu bar and the select the **Echo Off** option in the **Set Echo** dialog.

It is **strongly recommended** that you review the entire output file to ensure that the results are reasonable and that there are no error messages or warnings reported, etc. Errors encountered during the analysis & design can disable access to the post-processing mode. The information presented in the output file is a crucial indicator of whether or not the structure satisfies the engineering requirements of safety and serviceability.

#### Additional Notes
- Details about additional assistance from Bentley and Partners can be found at program menu
- Help->Technical Support
- Copyright (c) 1997-2017 Bentley Systems, Inc.
T.3 Post-Processing

If there are no errors in the input, the analysis is successfully completed. The extensive facilities of the Post-processing mode can then be used to:

- view the results graphically and numerically
- assess the suitability of the structure from the standpoint of safety, serviceability and efficiency
- create customized reports and plots

The procedure for entering the post processing mode is explained in tutorial 2 (on page 506).

Node results such as displacements and support reactions are available for all models. The methods explained in the first two tutorials may be used to explore these. For this example, you will examine the support reactions.

If beams are present in the model, beam results will be available too. As no beams are present in this model, this is not covered for this tutorial.

For plates, the results available are stresses, and “unit width” moments. There are several different methods for viewing these results, as explained in the next few sections.

T.3 Viewing stress values in a tabular form

1. On the View ribbon tab, select the Tables tool in the Windows group.

   The Tables dialog opens.

2. Select Plate Center Stress and click OK.
The **Plate Center Stress** table opens.

![Image of the Plate Center Stress table](image)

**Figure 90:** The table has the following tabs:

- **Shear, Membrane and Bending**
  - These terms are explained in [G.5.1 Plate and Shell Elements](#) (on page 2308). The individual values for each plate for each selected load case are displayed.

- **Summary**
  - This tab contains the maximum for each of the 8 values listed in the Shear, Membrane and Bending tab.

- **Principal and Von Mises**
  - These terms too are explained in [G.5.1 Plate and Shell Elements](#) (on page 2308). The individual values for each plate for each selected load case are displayed, for the top and bottom surfaces of the elements.

- **Summary**
  - This tab contains the maximum for each of the 8 values listed in the Principal and Von Mises tab.

- **Global Moments**
  - This tab provides the moments about the global X, Y and Z axes at the center of each element.

3. (Optional) Right-click in the table area and select **Print** from the pop-up menu.

### T.3 Changing the units of values in the output

The length and force units of the stresses and moments are displayed alongside the individual column headings for the terms.

1. On the **File** ribbon tab, select **Display Options** on the **Settings** tab.

   The **Options** dialog opens.
2. Select the **Force Units** tab and specify the required unit from the **Stress** and **Moment** fields.
3. (Optional) Click **Apply**
4. Click **OK**

### T.3 Limiting the load cases for which the results are displayed

Use the following procedure to change the load list used for present results in the Post Processing mode.

1. On the **Results** ribbon tab, select the **Select Load Case** tool in the **Configuration** group.

   ![Results Setup dialog](image)

   The **Results Setup** dialog opens.

2. Click `<<`.

   All load cases are moved from the Selected list to the Available list.

3. Select the load cases you want from the **Available** list and click `>`.

   The selected load cases are transferred from the **Available** list to the **Selected** list.
4. Click **OK**.

T.3 Stress Contours

Stress contours are a color-based plot of the variation of stress or moment across the surface of the slab or a selected portion of it.

1. On the **Results** ribbon tab, select the **Plate Stress** tool in the **View Results** group.

   ![Diagrams dialog](image)

   The **Diagrams** dialog opens to the **Plate Stress Contour** tab.

2. Select the load case number from the **Load Case** drop-down list.

   Stress values are known exactly only at the plate centroid locations. Everywhere else, they are calculated by linear interpolation between the center point stress values of adjacent plates.

   The **Enhanced** type contour chooses a larger number of points compared to the **Normal** type contour in determining the stress variation.

3. Select the specific type of stress for which you want the contour drawn from the **Stress type** drop-down list.

4. Setting the **View Stress Index** option will display a small table consisting of the numerical range of values from smallest to largest which are represented in the plot.

   Set the following:

   - Load case — 102: CASE 1 + CASE 3
   - Stress Type — Von Mis Top
Tutorials
T.3 - Analysis of a slab

Contour Type — Normal Fill
Index based on Center Stress checked
View Stress Index checked
Re-Index for new view checked

5. Click **Apply**.
The following diagram will be displayed.
T.3 Animating stress contours

The Diagrams dialog is used to provide a dynamic animation of stress plots.

In order to animate a diagram, such as the plate stress contour, you must first have a diagram displayed. Refer to T.3 Stress Contours (on page 599) for how to plot those results on the structure.

1. Either:
   - on the Results ribbon tab, select the Animation tool in the Animation group
   - or
   - if the Diagrams dialog is still open from the previous procedure, select the Animation tab

2. Select the Stress option.
3. (Optional) Set the **Target FPS 5**

   **Tip:** This will slow the animation down to make it easier to distinguish the frames.

4. Click **Apply**.

   The plate stress contours are animated loading and unloading.
5. To stop the animation, select the **No Animation** option and click **Apply** again.

### T.3 Creating AVI Files

You can save dynamic result, such as a deflection diagram in animation, to a video file. This feature is available in STAAD.Pro for node deflection, beam section displacement, mode shape and plate stress contour diagrams. These files can then be viewed using video player programs such as the Windows Media Player.

1. On the **Utilities** ribbon tab, select the **Create AVI File** tool in the **Utilities** group.

The **Create AVI File** dialog opens.
Total No. of Frames  Sets the number of frames used to capture the movement. In an animated view, the movement from one extremity to the other is captured as several frames.

Frame Rate /sec  sets the speed of the motion

The rest of the options in the above dialog are for the type of diagram from which the video file is to be created. Certain items such as Mode Shape and Plate Stress contour are disabled if the required data of that type are not present in the STAAD file, such as a modal extraction, or finite elements.

2. Select the Stress Contour option for Animation Type and then select Von Mis Top from the Plate Stress Type drop-down list.

3. Click OK.  
A dialog opens to specify the file name.

4. Type a file name and location for the video file and then click OK.

The Video Compression dialog opens.
5. (Optional) Select a Compressor option and set the Compression Quality value.

   **Note:** Video files can be quite large, and compression is a technique used reduce the size of these files, though some video smoothness is lost in this process.

6. Click **OK** to begin creating the video file.

   When the file has been generated, a message opens indicating that the operation was successful.

7. Click **OK** to dismiss.

   The file with the extension *AVI* is saved in the same folder where the STAAD input file is located.

---

**T.3 Viewing plate results using element query**

Element Query is a facility where several results for a specific element can be viewed at the same time from a single dialog.

1. On the **Results** tab, select the **Plate Cursor** tool in the **Selection** group.

2. Either:
   
   - Double-click on element 4
   
   or

   - select element 4 and then select the **Properties** tool in the **Model** group on the **Plate Tools** ribbon tab.

   **Tip:** Press `<Shift+P>` to display the plate numbers.

   The **Plate** dialog opens.
The various tabs of the query box enable one to view various types of information such as the plate geometry, property constants, stresses, etc., for various load cases, as well as print those values.

Some example tabs of this dialog are shown in the following figures.
Tutorials
T.3 - Analysis of a slab

The image shows a software interface for the analysis of a slab using STAAD.Pro. The interface includes options for specifying material properties and physical properties, as well as load lists. The interface displays the results for principal stresses, von mises stresses, and Tresca stresses for the slab.

Material Properties:
- Elasticity: 21,718,456 kN/mm²
- Density: 2402,6156 kg/m³
- Poisson: 0.17
- Alpha: 1e-05

Physical Properties:
- Node 7: Thickness = 0.300000011
- Node 6: Thickness = 0.300000011
- Node 11: Thickness = 0.300000011
- Node 4: Thickness = 0.300000011

Load List:
- 1: DEAD LOAD

Stress Results:
- Principal Stresses:
  - Top (N/mm²): -0.972646, 0.946139, 0.972646
  - Bottom (N/mm²): 0.972646, 0.946139, 0.972646

- Von Mises Stresses:
  - Top (N/mm²): 0.946139, 0.946139, 0.946139
  - Bottom (N/mm²): 0.946139, 0.946139, 0.946139

- Tresca Stresses:
  - Top (N/mm²): 0.972646, 0.972646, 0.972646
  - Bottom (N/mm²): 0.972646, 0.972646, 0.972646
T.3 Producing a report

Produce a report consisting of the plate principal stresses, for all plates, sorted in the order from Low to High of the Principal Maximum Stress (SMAX) for load cases 101 and 102.

Occasionally, you will need to obtain results conforming to certain restrictions, such as, say, the resultant node displacements for a few selected nodes, for a few selected load cases, sorted in the order from low to high, with the values reported in a tabular form.

1. On the Results tab, select the Plate Cursor tool in the Selection group.

2. Select the all the plate elements.
   
   **Tip:** Drag a window around all the elements in the view area or press <Ctrl+A>.

3. On the Results ribbon tab, select the Reports > Principal Stresses tool in the Reports group.

   The Plate Forces dialog opens.

   ![Plate Forces Dialog](image)

4. Specify the report contents:
   a. Select the Sorting tab.
   b. Select the SMAX option in the Sort By Plate Stress group.
c. Select **List from Low to High** option in the **Set Sorting Order** group.

d. Clear the **Absolute Values** check box in the **If Sorting done** group.

5. Select the load cases to use:
   
a. Select the **Loading** tab.

   ![Plate Forces window](image)

   b. Select load cases **101** and **102** in the **Available** list and click [>] to add them to the **Selected** list.

6. (Optional) You can save this report for future use,
   
a. Select the **Report** tab

   b. Type a **Title** for the report.

   c. Set the **Save Report** check box.

7. Click **OK**.

   The Plate Forces table opens to display the table of maximum principal stress with SMAX values sorted from Low to High.
8. (Optional) To print this table, right-click anywhere within the table and select **Print**

To transfer the contents of this table to a Microsoft Excel file, click the **Plate** label in the top-left corner of the table. The entire table is selected. Right-click and select **Copy** from the pop-up menu. You can now paste the table contents into a Microsoft Office Excel spreadsheet or other spreadsheet file.

**T.3 Viewing Support Reactions**

Use the nodal results page to obtain support reaction results.

1. Select the **Reactions** page in the **Postprocessing** page control bar.

   The reactions at the supports will be displayed on the drawing and the Support Reactions table is displayed on the right side of the program window.
The six values — namely, the three forces along global X, Y and Z, and the three moments Mx, My and Mz, in the global axis system — are displayed in a box for each support node.

2. Display of one or more of the six terms of each support node may be toggled off in the following manner.
a. On the **Results** ribbon tab, select the **Annotate** tool in the **Configuration** group. The **Annotation** dialog opens.

![Annotation dialog](image)

b. Select the **Reactions** tab.

c. Clear the degree of freedom check boxes in the **Direct** or **Bending** groups you want to hide from display.

d. Click **Annotate** and then **Close**.

The drawing will now contain only the selected items.

3. **(Optional)** To change the load case for which the reactions are displayed, select the desired case from the **Load** drop-down in the program status bar.

![Load drop-down](image)

4. On the **Support Reactions** table, select the **Summary** tab.

**Tip:** You can also open this table by selecting **Tables > Reactions** tool in the **View Results** group on the **Results** ribbon tab.
The summary tab contains the maximum value for each of the 6 degrees of freedom along with the load case number responsible for it.

Refer to T.3 Changing the units of values in the output (on page 597) to change the units in which these values are displayed.

This brings us to the conclusion of this tutorial.
This section of the help describes methods used to model your structure in STAAD.Pro. This section begins by detailing how to model analytical elements using the Analytical Modeling workflow. Following that are sections on how to model the structure using other workflows and utilities in STAAD.Pro.

M. Navigating the Graphical View Window

This section describes how to control the graphical display of your model.

M. To select a center of rotation at a node

Used to select an node as the center of rotation. When toggled on, pressing <Ctrl+Shift> and clicking a node will set that node as the center of rotation.

1. Either:
   - On the View ribbon tab, select the Toggle View Rotation Mode tool in the Rotation group.
   - Or
   - On the View ribbon tab, select the Always Fit in Current Window tool in the Rotation group.

   **Note:** The icon for the Toggle View Rotation Mode is depressed when in this mode (and there is no check on the View > Always Fit in Current Window menu item).

   A message dialog appears to remind you how to next select a center of rotation.

2. Hold down the <Ctrl+Shift> keys and click on a node.

   A reticle is placed on this node to indicate it is the center of rotation.

3. Either:
   - Use the rotate tools found in the Rotate toolbar or the arrow keys to rotate the structure about this node.
   - Or
   - Hold down the right mouse button while dragging the pointer to free rotate the model about this node.

4. Repeat steps 3 and 4 to re-center and rotate the structure.

5. To return the center of rotation to the center of the structural model:
   - select the Toggle View Rotation Mode tool
   - Or
select the **Always Fit in Current Window** tool such that a check mark appears or

select the **Use Center of the structure as rotational Center** option in the **Orientation** dialog.

**Tip:** You may specify the exact center of rotation coordinates at any point using the **Orientation** dialog.

### M. To view a 3D rendering of your model

To display the model with full 3D sections and lighting, use the following procedure.

Depending on the material used (steel, concrete, etc.), an appropriate texture will be applied to the structure. A property or material must be assigned to the entities of the model before this feature can be used. This is for visual and presentation purposes only.

**Note:** The 3D rendering is used to display the model only. You cannot select model objects or otherwise manipulate the model in this view.

1. On the **View** ribbon tab, select the **3D Rendering** tool in the **Windows** group.

A new view window opens with the model displayed as a 3D rendering.

2. Navigate the rendering view as follows:

<table>
<thead>
<tr>
<th>To…</th>
<th>Do this…</th>
</tr>
</thead>
<tbody>
<tr>
<td>rotate the structure</td>
<td>left-click in the view and drag the mouse in any direction</td>
</tr>
<tr>
<td>pan the structure</td>
<td>click-and-drag the middle mouse button (typically the scroll wheel)</td>
</tr>
<tr>
<td>zoom in/out</td>
<td>scroll the mouse wheel up or down</td>
</tr>
</tbody>
</table>

3. (Optional) To generate a picture for inclusion in reports:

   a. Right-click and select **Take Picture** from the pop-up menu.

   The **Picture #** dialog opens.

   b. Type a picture **ID** and **Caption**.

   c. Click **OK**.

4. Click the [X] in the top, right-hand corner of the window to close the view.

### M. 3D Rendering View Right-click View Menu

<table>
<thead>
<tr>
<th>Menu item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>View Axes</td>
<td>Toggles the display of the global axes.</td>
</tr>
<tr>
<td>Perspective</td>
<td>Toggles the perspective lens for the rendered window.</td>
</tr>
<tr>
<td>Wireframe View</td>
<td>When selected, solid rendering is turned off. Only the outline of shapes are shown.</td>
</tr>
</tbody>
</table>
### Menu item

<table>
<thead>
<tr>
<th>Menu item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Lighting</td>
<td>Toggles the light source. Turning this feature off removes any reflection.</td>
</tr>
<tr>
<td>Lights (list)</td>
<td>Select the light color from the list.</td>
</tr>
<tr>
<td>Change Light Color</td>
<td>The lighting is by default gray to resemble the color of steel. This can be changed to any other color.</td>
</tr>
<tr>
<td>Enable Texture Mapping</td>
<td>The structure will be displayed with a unique texture.</td>
</tr>
<tr>
<td>Change Entity Color...</td>
<td>Opens the Change Entity Color dialog, which is used change the color of structure entities by class.</td>
</tr>
<tr>
<td>Change Background Color...</td>
<td>Opens a color selector dialog, so the default background color can be changed.</td>
</tr>
<tr>
<td>Change Font...</td>
<td>Opens a font selection dialog, so the text display can be changed.</td>
</tr>
<tr>
<td>Model View Details</td>
<td>Opens the Structure Diagram Info dialog, which contains a summary of the entity counts in the structure.</td>
</tr>
<tr>
<td>Take Picture</td>
<td>Takes a STAAD image of the rendered view for inclusion in reports. A picture ID dialog opens to name the image.</td>
</tr>
</tbody>
</table>

### M. Labels

STAAD.Pro has numerous options for displaying labels in the view window.

**M. To switch on labels for nodes, beams, plates, etc.**

Labels are a way of identifying the entities we have drawn on the screen.

1. Either:

   Select the **Labels** tool

   or

   Right-click anywhere in the View area and select **Labels** from the pop-up menu. The **Diagrams** dialog opens.

2. Select the **Labels** tab and then select the options for the appropriate labels (examples shown in the following figure).
Modeling

M. Navigating the Graphical View Window

![Diagram of STAAD Pro's Graphical View Window with various options for modeling and visualization settings.](image)

For quick access to the labels using keyboard hotkeys, press Shift + the letter shown in brackets.
3. Click **OK** to update the View window and close the dialog.
4. To change the font of the node/beam labels, select **View > Options**.
   
a. Select the **File** ribbon tab.
   
The STAAD.Pro Backstage view opens.

b. On the **Settings** tab, select **Display Options**.

   The **Options** dialog opens.

c. Select the appropriate tab (Node Labels / Beam labels) and then click **Font** to make the desired changes.
d. Click OK to close the Font dialog.

e. Click OK to close the Options dialog.

M. To change the structural tool tip options

Structural tool tips offer a facility for displaying any customized input or output information about a node, beam, plate or solid element when the mouse cursor is placed over the structural entity. The tool tips are similar to the ones displayed when the mouse cursor hovers over a toolbar icon.

1. Select the File ribbon tab.
   The STAAD.Pro Backstage view opens.
2. On the Settings tab, select Structural Tooltip Options.
   The Tool Tip Options dialog opens.
3. Check the **Show Tool Tip** option.

4. (Optional) Change the **Tip Delay**

   This number is expressed in milliseconds (i.e., $1,000 = 1$ second).

5. For a selected model entity (Node, Beam, etc. in the left list), set the information and results you want to display in the tool tip in the right list.

   The options (items that can be displayed) for each entity are shown under the **Options** list. A check mark signifies that the particular data item will be displayed in the tool tip. An option with a "+" next to it signifies that further options can be enabled or disabled. A red "X" indicates the data will not be shown in the tool tip. Simply click on the check box to turn an option on or off.

6. Click **OK**.

---

**Example**

Structural tool tips can be configured to display a wide variety of information by hovering over a model entity, as shown in the following figure.
Note: The tool tips automatically display the results for the active load case. All values are reported in the current display units.

M. To switch individual object label display

To control the display of individual node, beam, plate, or solid labels, use the following procedure.

These tools activate the Partial Labeling Mode, which allows you to control the display of individual object labels in STAAD.Pro.

1. On the View ribbon tab, select one of the following tools in the Labels group:

   **Individual Node Label**

   or

   **Individual Beam Label**
2. Select the model object that you want to switch the label state.
   The model object must be of the same type as the selected tool.
   If this is the first time you are switching individual labels, you will be prompted that the program will turn on
   Partial Labeling Mode. Click **Yes** to proceed.

M. Views

You can navigate the view, control the display of model objects, and save named views in STAAD.Pro.

M. Displaying a Portion of the Model

Sometimes, the large number of entities that are drawn on the screen may make it difficult to clearly see the
details at any particular region of the structure. In such cases, one is confronted with the task of decluttering the
screen or looking at specific regions or entities while removing the rest of the structure from the view.

There are different methods in STAAD.Pro by which you can view a portion of the structure.

M. To cut a section of a model

The file US 8. Concrete Design for a Space Frame.STD is used to demonstrate this feature.

1. (Optional) Press `<Shift+N>` to display the node numbers.
   This will aide in specifying a node number in the following step.
2. Use the cut section tool:
   a. On the Utilities ribbon tab, select the Structure Tools tool in the Geometry Tools group.
   
   ![Structure Tools icon]

   b. Select the Cut Section tool from the drop-down list.
   
   ![Cut Section icon]

   The Section dialog opens.
3. Specify a cut plane by joint and plane orientation (range by joint method):
   a. Select the Range By Joint tab.
   b. Select the X - Z Plane option.
   c. Select 10 from the With Node # drop-down list (which contains all node numbers in the model).
      
      Tip: You can select any node with in this same plane to achieve the same result.
   d. Click OK.

4. To restore the original view, select the Whole Structure tool in the Tools group on the View ribbon tab.

   Tip: Alternatively, you can click Show All on the Section dialog.

5. Specify a cut plane by minimum and maximum distances and plane orientation (the range by min/max method):
   a. Repeat step 2 to open the Section dialog.
   b. Select the Range By Min/Max tab.
c. Select the **X-Z Plane** option.

d. Type 10 in the **Minimum** field and type 14 in the **Maximum** field.

The **Minimum** and **Maximum** values are the boundary distances along the axis perpendicular to the sectional plane. Every object lying entirely between these two distances will be displayed.

**Note:** When using this method, make sure that the current input units of length are in the intended units.

6. Repeat step 4 to restore original view.
7. Display only the nodes for quick selection (the Select to View method):
   a. Select the **Select To View** tab.

   ![Select To View](image)

   **Figure 93:**

   b. Select the **Select To View** option.
   c. Check the **Node** option.
   d. Click **OK**.
8. Select the **Whole Structure** tool to restore original view.

**Note:** You can save these views by selecting the **View Management > Save View** tool in the **Views** group on the **View** ribbon tab. Provide a title for the new view. These saved views may later be opened by selecting the **Open View** tool in the **Views** group on the **View** ribbon tab.

### M. To create a new view

The file **US.8. Concrete Design for a Space Frame.STD** is used to demonstrate this feature.

New view windows are helpful for performing such operations as adding and deleting members, assigning properties, loads, supports, and more. A new view of a selected portion offers the advantage of de-cluttering the screen and limiting the displayed objects to just a few chosen entities.

1. On the **View** ribbon tab, select the **Front View** tool in the **Tools** group.

2. In the view window, drag a window area around the middle level of beams to select them.

**Tip:** Make sure that the **Beam Cursor** tool is the active selection tool on the **Select** ribbon tab in the **Cursors** group.

The selected members are highlighted.
3. (Optional) On the View ribbon tab, select the Isometric View in the Tools group.

4. Either:
   On the View ribbon tab, select the New View tool in the Views group.
   
or
   Right-click anywhere in the current view window and select New View from the pop-up menu.
The **New View** dialog opens.

The dialog includes options open the new view in a new (child) window or to replace the current (parent) view window.

5. Select the **Create a new window for the view** option and then click **OK**.

The portion of the structure that we selected is displayed in a new window.

**Tip:** Multiple child view windows may be created in this way.

6. Save the view for later use:
   a. On the **Views** ribbon tab, select the **View Management Save View** tool in the **Views** group.

   The **Save View As** dialog opens.
   b. Type a name for the view.
   c. Click **OK**.

   The view window is titled with the view name. You can

7. Close the new view window by clicking close [X] in the top-right corner.
8. Repeat steps 2 through 4 to start another New View.
9. Select the **Display the view in the active window** option and click **OK**.

The full structure is hidden and the selected portion is displayed in the View window.

10. To restore the original view, select the **Whole Structure** tool in the **Tools** group on the **View** ribbon tab.
M. To insert custom text in a view

To add custom text to the view window and, subsequently, pictures taken for reports, use the following procedure.

The text can serve as comments or titles to pictures and result diagrams. The added text can be plotted too.

1. Select the **Insert Text** tool in the **Display** group on the **Utilities** ribbon tab.

   The mouse pointer changes to the text cursor (\(\text{ insertion symbol}\)).

2. Click in the view window where you want to insert the text.

   The **Write Text to Insert** dialog opens.

3. (Optional) Click **Font** to set the type display.

4. Type the text into the text field and then click **OK**.

5. Either:

   Repeat steps 2 through 4 to insert additional text items.

   or

   Repeat step 1 to turn off the insert text tool.

6. (Optional) To modify previously inserted text:

   a. Select the **Text Cursor** tool in the Selection group on the **Geometry, Results**, or **Member Design** ribbon tabs.

   b. Double-click on the text you want to modify.

      An edit dialog opens with the existing text.

   c. Make changes and then click **OK**.

   d. Click-and-hold the left mouse button on the text to move it to another location in the view window.

7. (Optional) To delete previously inserted text:
a. Select the Text Cursor tool in the Selection group on the Geometry, Results, or Member Design ribbon tabs.

b. Click on the text you want to delete.

c. Press <Delete>.

M. To display loads graphically

You can display the load diagrams and load values on the model.

1. On the Loading ribbon tab, select the current Load from the drop-down list in the Display group.

   ![Load Selection](image)

   Tip: The current load case number is displayed in the lower, right-hand side of the view window as well as in the application status bar.

2. Either:

   Select the Labels tool

   or

   Right-click anywhere in the View area and select Labels from the pop-up menu.

   The Diagrams dialog opens.

3. Either:

   a. select the Loads and Results tab.

   b. Check the Loads option.

   c. (Optional) Click the color squares for Direct or Moment to change the load pattern colors.

   d. Click Apply.

   The loads are graphically displayed on the model.
4. a. Select the Labels tab.
   b. Set the Load Values check box in the Loading Display Options group.
   c. Click OK.

The load values are displayed for the current load case, as seen here for the file US.8. Concrete Design for a Space Frame.STD.
5. (Optional) To change the units displayed:
   a. Select the **File** ribbon tab.
      The STAAD.Pro Backstage view opens.
   b. On the **Settings** tab, select **Display Options**.
      The **Options** dialog opens.
   c. Select the **Force Units** tab.
      The **Options** dialog opens.
d. Select the **Force** and **Distributed Force** values as needed.

e. Click **OK**.
   
The values are updated with the new units.

### M. To identifying beam start and end

Beam ends can be colored to easily identify the start and end joints of a beam. By default, the start ($i$) joint is colored green and the end ($j$) joint is colored blue.

1. Either:
   
   Select the **Labels** tool

   or

   Right-click anywhere in the View area and select **Labels** from the pop-up menu.

   The **Diagrams** dialog opens.

2. Check the **Beam Ends** option in the **Beams** group.

3. Click **OK**

   **Tip:** Alternatively, you can press `<Shift+E>` to toggle the beam end colors.
The beam ends are colored for the entire structure.

The file US.1. Plane Frame with Steel Design.STD is used to demonstrate this feature.

Alternatively, you can hover your mouse over any beam momentarily and the beam ends for that member are displayed using the same colors.
M. Rotation tools

These tools found on the View ribbon tab can rotate your model to a predefined orientation.

<table>
<thead>
<tr>
<th>Tool name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Isometric View</td>
<td>Displays the structure in the isometric view. The angle which defines isometric view is generally $X = 30, Y = 30, Z = 0$</td>
<td>![Example Image]</td>
</tr>
<tr>
<td>Tool name</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Front View</td>
<td>Displays the structure as seen from the positive Z axis. When the global Y axis is vertical, this is the elevation view, as looking towards the negative direction of the Z-axis.</td>
<td><img src="image1" alt="Front View Example" /></td>
</tr>
<tr>
<td>Back View</td>
<td>Displays the structure as seen from the negative Z axis. When the global Y axis is vertical, this is the elevation view, as seen looking towards the positive direction of the Z-axis.</td>
<td><img src="image2" alt="Back View Example" /></td>
</tr>
<tr>
<td>Left View</td>
<td>Displays the structure as seen from the negative X axis. When the global Y axis is vertical, this is the side elevation, as seen looking towards the positive direction of the X-axis.</td>
<td><img src="image3" alt="Left View Example" /></td>
</tr>
<tr>
<td>Right View</td>
<td>Displays the structure as seen from the positive X axis. When the global Y axis is vertical, this is the side elevation, as seen looking towards the negative direction of the X-axis.</td>
<td><img src="image4" alt="Right View Example" /></td>
</tr>
</tbody>
</table>
### M. To display master nodes

To highlight master nodes in a model that contains master/slave joints, use the following procedure.

**Tip:** Open example 26 to demonstrate this procedure for yourself.

1. Either:
   - on the **View** ribbon tab, select the **Label Settings** tool in the **Labels** group
   - or
   - in the view window, right-click and select **Labels** from the pop-up menu
   - The **Diagrams** dialog opens to the Labels tab.

2. Check the option from **Master Slave** in the General group.

3. Click **Apply**.

   **Tip:** Press `<Shift+L>` to highlight master nodes quickly.

   The master nodes are highlighted with green cubes.
4. Click OK.

Related Links
- Diagrams dialog (on page 2927)

- EX. UK-26 Modeling a Rigid Diaphragm Using Master-Slave (on page 4855)

M. Creating Model Objects
This section describes the tools used in STAAD.Pro to model your structure.

M. Drawing Aids

M. To add a grid for drawing objects
To add a grid for drawing beams or plates, use the following procedure.
Only one grid may be displayed at a time. However, you may have multiple grids associated with your model.

**Note:** Grids added to the model will be available to use in both the Snap Node/Beam, Snap Node/Plate, and Snap Node/Solid dialogs.

1. Either:
   - On the Geometry ribbon tab, select the Grids > Beam Grid tool in the Structure group.

![Beam Grid](image1)

   or
   - On the Geometry ribbon tab, select the Grids > Triangular Plate Grid tool in the Structure group.

![Triangular Plate Grid](image2)

   or
   - On the Geometry ribbon tab, select the Grids > Quad Plate Grid tool in the Structure group.

![Quad Plate Grid](image3)

   or
   - On the Geometry ribbon tab, select the Grids > Solid Grid tool in the Structure group.
The corresponding Snap Node/Beam, Snap Node/Plate, or Snap Node/Solid dialog opens. If an existing grid is selected in this dialog, this grid is displayed in the view window.

2. Click Create.
   A pop-up dialog opens for defining grid details.

3. Select the type of grid from the drop-down list.

<table>
<thead>
<tr>
<th>Grid type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear</td>
<td>a Cartesian grid with even spaces along both of the axis.</td>
</tr>
<tr>
<td>Radial</td>
<td>a polar grid with even spaces between rays and radial lines.</td>
</tr>
<tr>
<td>Irregular</td>
<td>a Cartesian grid with irregular spaces along both of the axis.</td>
</tr>
</tbody>
</table>

The pop-up dialog fields update with the grid type selection.

4. Type a grid Name to identify the grid in the Snap Node/Beam dialog.

5. Specify the location of the grid with respect to the global axes:
   a. Select the parallel global Plane for alignment (or reference when an angle is specified).
   b. (Optional) Select a global axis and then type an Angle of Plane to incline the grid with respect to that axis.
   c. (Optional) (For Irregular grids) Set the option to Use Arbitrary Plane and then type the vectors of the grid X and Y axis.
      This method can be used instead of specifying the Plane and Angle of Plane.
   d. Type global coordinates from the global origin to the Grid Origin.

   Tip: Click the node selection tool (pencil) and then click on an existing node in the model to use as the grid origin.

6. Specify the Construction Lines for the grid:

<table>
<thead>
<tr>
<th>Grid type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear</td>
<td>For both grid X and Y, type the number of grids spaces to the Left and Right of the origin, the Spacing (in current units) between each grid line, and (optionally) a Skew angle.</td>
</tr>
<tr>
<td>Radial</td>
<td>Type the Start Angle and Sweep to specify the beginning and end of the radial lines along with the number of bays (spaces between radial lines). Type the inner-most and outer-most radius in the Radius 1 and Radius 2, respectively, along with the number of Bays (spaces between arcs).</td>
</tr>
<tr>
<td>Irregular</td>
<td>Type the distance between each consecutive grid line in the current units along each axis.</td>
</tr>
</tbody>
</table>

7. Click OK.
   The pop-up dialog closes and the new grid name is added to the list.

8. Check the name of the grid in the list that you want displayed in the view window.

Click Edit to make changes to the currently selected grid in the list. You can change the grid orientation and construction lines but the type of grid cannot be changed.

Related Links
- Snap Node-Beam dialog (on page 2895)
- Linear (on page 2897)
- Radial grid dialog (on page 2897)
- Irregular grid dialog (on page 2898)
M. To import a STAAD.Pro grid file

To import a STAAD.Pro grid file which was contains grids used in another model, use the following procedure.

Any time you save a model with custom grids, the grid data is saved into a STAAD.Pro grid file (file extension .grd) with the same file name and location as the STAAD input file.

1. Either:
   - On the Geometry ribbon tab, select the Grids > Beam Grid tool in the Structure group.

   ![Image of Beam Grid tool]

   or
   - On the Geometry ribbon tab, select the Grids > Triangular Plate Grid tool in the Structure group.

   ![Image of Triangular Plate Grid tool]

   or
   - On the Geometry ribbon tab, select the Grids > Quad Plate Grid tool in the Structure group.

   ![Image of Quad Plate Grid tool]

   or
   - On the Geometry ribbon tab, select the Grids > Solid Grid tool in the Structure group.

   The corresponding Snap Node/Beam, Snap Node/Plate, or Snap Node/Solid dialog opens. If an existing grid is selected in this dialog, this grid is displayed in the view window.

2. Click Import.
   - The Import Options dialog opens.

3. Select STAAD.Pro Grid (.grd) and then click OK.
   - An Windows Open dialog opens.

4. Select the STAAD.Pro grid file and then click Open.
   - The grids in the file are added to the Snap Node/Beam dialog.

M. To import a DXF file as a grid

To import an AutoCAD® DXF file to use as a drawing grid, use the following procedure.

The straight lines within a DXF file can be imported as a grid. Complex shapes and curved lines will not be imported.

1. Either:
   - On the Geometry ribbon tab, select the Grids > Beam Grid tool in the Structure group.
or
On the **Geometry** ribbon tab, select the **Grids > Triangular Plate Grid** tool in the **Structure** group.

or
On the **Geometry** ribbon tab, select the **Grids > Quad Plate Grid** tool in the **Structure** group.

or
On the **Geometry** ribbon tab, select the **Grids > Solid Grid** tool in the **Structure** group.

The corresponding **Snap Node/Beam, Snap Node/Plate, or Snap Node/Solid** dialog opens. If an existing grid is selected in this dialog, this grid is displayed in the view window.

2. Click **Import**.
   The **Import Options** dialog opens.

3. Select the **DXF** option and click **OK**.
   The **DXF Import** dialog opens.

4. In the File Name field, either:
   - type the file path and file name of the DXF file
   - or
   - click [...] locate the file using the **Open DXF File** dialog
   The layers and line data is read and displayed graphically.

5. Select the layer number containing the line data you want to use from the **Layers** drop-down list.
   The lines are displayed in the list view and graphically.

6. (Optional) Uncheck any lines you do not want to include in the imported grid.
   The lines are hidden in the view window.

7. (Optional) Type a **Name** for the imported grid.
   By default, the name of the DXF file is used.

8. Select the **Unit** to use for the grid.

   **Tip:** The drop-down list contains most common length units. Use the up or down arrows to navigate through the options.

9. Click **OK**.
   The Imported Grid pop-up dialog opens.

10. (Optional) Specify the **Angle of Plane** and **Grid Origin** to orient the grid.

11. Click **OK**.
When you save your model, the imported DXF grid will be saved to the corresponding STAAD.Pro grid file (file extension .grd).

**Related Links**
- *Imported Grid dialog* (on page 2900)
- *DXF Import dialog* (on page 2899)

## M. Beams

### M. To set attributes for new beams

To specify a set of attributes to automatically assign to new beams, use the following procedure.

For member profiles and member end releases, you will need to add the corresponding specification to your model before you can select it for most attribute sets.

**Tip:** The predefined attribute sets have some pre-populated values that will be added to your model automatically, though.

In STAAD.Pro, you will often assign attributes (beta angle, end offsets, material, profile, etc.) after you have placed a member. However, you can also assign attribute sets when creating new members by defining these ahead of time. STAAD.Pro allows you to create and edit named attribute sets so you can easily change between attribute sets.

**Note:** This feature is not active by default so new members will not have any attributes assigned initially.

1. On the **Geometry** ribbon tab, select **Add Beam > Set New Beam Attributes** in the **Beam** group. The **Define Member Attributes** dialog opens.
2. Select an attribute set in the list. **Tip:** There are several named sets which can be used or you can simply use the default “(None)” set.
3. Check the box for each attribute you want assigned. **Note:** This option can only be checked for one attribute set.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Member Property</td>
<td>Check to <strong>Assign Profile with Material</strong> and then select the profile and associated material from the drop-down list.</td>
</tr>
<tr>
<td>Beta Angle</td>
<td>Check to <strong>Assign Member Rotation</strong> and then select the option for rotation from the list. Type in the <strong>Angle in Degrees</strong> if you select that option.</td>
</tr>
<tr>
<td>Member Release</td>
<td>Check to <strong>Assign to Member Start</strong> and <strong>Assign to Member End</strong> as needed. Select a end release specification from the drop-down list for each end you have added a member release.</td>
</tr>
</tbody>
</table>

4. Click **Save**. The attribute set is updated with the new specification selections.
5. Check the option to **Assign these attributes when creating members**.
   **Note:** This option can only be checked for one attribute set.
6. Click **OK**.
M. To add beams by drawing on a grid

1. On the Geometry ribbon tab, select the Grids > Snap Grid Beam tool in the Structure group.

   The Snap Node-Beam dialog (on page 2895) opens and the current grid is displayed in the active View window.

   **Tip:** The dialog and grid are automatically opened if you select Start adding beams in the New model wizard.

2. (Optional) Either:
   - click Edit to edit the currently selected grid
   - or
   - click Create to create a new custom grid (radial and irregular grids must be custom)

3. (Optional) Set the Snap to existing nodes too

   **Note:** Existing nodes have precedence over grid intersections, in order to prevent creating duplicate nodes (on page 889).

4. If it is not already active, click Snap Node/Beam in the Snap Node/Beam dialog.

5. In the Active view window, click any grid intersection or existing node (if the option was set) to select the start point of a new beam member.

   A cross icon "snaps" to the nearest grid line intersection or existing node to the mouse pointer. This indicates the tentative point for placing a beam end. Once the start end is selected, a red circle indicates the start point and a line is rubber-banded to the snap point nearest the mouse pointer.

6. Click the end point of the beam.

7. Repeat steps 5 and 6 until you are finished drawing beams.

8. To stop drawing beams, either:
   - press <Esc>
   - or
   - click Snap Node/Beam in the Snap Node/Beam dialog

M. To add beams with new nodes

To add beams between existing nodes or along beams by generating new nodes, use the following procedure.

1. On the Geometry ribbon tab, Add Beam tool in the Beam group.

   The mouse pointer changes to the Add Beams cursor (➕).

2. Click on any point along the first beam where the starting node of the new beam will lie.

   If the program detects you are clicking on an existing node, skip to Step 6.

   If an existing node is not present at that point, a dialog box will prompt for a new node to be created.
3. Click **Yes**. The **Insert Nodes into Beam #** dialog opens. The value in the **Distance** edit box is the exact location clicked on from the start of the beam.

4. (Optional) Edit the **Distance** value as necessary.

   **Tip:** Other nodes can also be generated along the beam as well. For more information on how to use the **Insert Node** dialog box, please refer to [M. To insert a node in a single member](on page 697).

5. Click **OK**

   A new node is created on the selected beam and a the new beam member is “rubber banded” to this point.

   **Tip:** If the new node input is not within a close proximity of the point clicked on the screen (that which resulted in the dialog opening), no “rubber band” line will be shown. In this case, simply click on the new node to start the creation of the beam.

6. Click a point along another beam or an existing node to specify the end point of the new beam.

   If this is not at an existing node, refer to steps 2 through 5 for inserting a new node into a beam.

7. To stop adding beams:

   Press `<Esc>`

   or

   select any tool

**Related Links**

- [TR.12 Member Incidences Specification](on page 2428)

**M. To add beams from mid-points**

1. On the **Geometry** ribbon tab, select the **Add Beam > Add Beam Between Mid-Points** tool in the Beams group.

   ![Add Beams cursor](image)

   The mouse pointer changes to the Add Beams cursor (🔗).

2. Click on any point along the first beam where the starting node of the new beam will lie.

   A new beam member is "rubber banded" to this point.

3. Click on any point along the second beam where the end node of the new beam will lie.

   New nodes are created on the selected beams at their mid-points and a the new beam member connects these two new points.

4. Repeat steps 1 through 3 to continue adding beams.

5. To stop adding beams:

   Press `<Esc>`

   or

   select any tool
M. To add beams perpendicular to existing beams

1. On the **Geometry** ribbon tab, select the **Add Beam by Perpendicular Intersection** tool in the **Beam** group.

   The mouse pointer changes to the Add Beams cursor (_attach_point).

2. Click on any point along the first beam where the starting node of the new beam will lie. A new beam member is "rubber banded" to this point.

3. Click on any point along the second beam where the end node of the new beam will lie. A new node is created on the selected beam at the at the calculated perpendicular point and a the new beam member is added.

4. Repeat steps 2 and 3 to continue adding beams.

5. To stop adding beams:
   - Press `<Esc>`
   - or
   - select any tool

M. To add a curved beam

To add a curved beam between two existing nodes, use the following procedure.

Curved members may only be created between two existing nodes. Any non-tapered cross-section is permitted for curved members. The internal angle subtended by the arc must be less than 180 degrees.

**Note:** The design of curved members is *not* supported.

1. On the **Geometry** ribbon tab, select the **Add Beam > Add Curved Beam** tool in the **Beam** group.

   **Tip:** This tool is contained on a drop-down list below the **Add Beam** tool.

   The pointer changes to the Add Curved Beam cursor (_attach_point).  
2. Click on the start and end nodes, respectively.
   - The **Curve Beam Properties** dialog opens.
3. Type the **Radius of Curvature** (in current units of length) and the **Gamma Angle** (in degrees) values.

   The gamma angle, \( \gamma \), is the angle between the member local Y axis and the plane of the circular arc of the member.

4. Click **OK**.
   The curved beam will be added to the model.

5. Repeat steps 2 through 4 to add more curved beams.

6. To stop adding beams:
   - Press `<Esc>`
   - or
   - select any tool

**Related Links**
- *G.6.8 Curved Members* (on page 2329)
- *TR.20.8 Curved Member Specification* (on page 2475)

**M. To split a beam at selected node(s)**

1. Select one or more nodes located along a beam.
2. On the **Geometry** ribbon tab, select the **Break Beams at Selected Nodes** tool in the **Beam** group.
A message box appears which displays the number of new beams created.

3. **Click OK**
   The dialog closes.

### M. To stretch a member

1. Select one or more members which are to be extended.
2. On the **Geometry** ribbon tab, select the **Geometry > Stretch Selected Member(s)** tool in the **Beam** group.

   The **Stretch Member(s) dialog** (on page 2908) opens.

3. **(Optional)** Click the drop-down list in the **Select member(s)** and then uncheck any members you do not wish included in the stretch operation.

4. Specify the method of stretch and required parameters:
   - Select **To a point** and then type the coordinates of an arbitrary point
     
   - Select **Through a distance** and then select the member end and distance to extend to
     
   - Select **To an existing node** and then select the node number
     
     **Tip:** Click the tool to graphically select a node.

   or

   - Select **To an existing member** and then select the member number
     
     **Tip:** Click the tool to graphically select a member.

5. **Click OK**

### Related Links

- **Stretch Member(s) dialog** (on page 2908)

### M. To merge two or more members

To merge two or more members into a single member, use the following procedure.

1. Select the beams to be merged.
2. On the **Geometry** ribbon tab, select the **Merge Selected Beams** tool in the **Beam** group.
The Merge Selected Beams dialog opens.

3. Specify the member properties the merged member will have.
4. Click Merge.

Related Links
- Merge Selected Beams dialog (on page 2909)

M. To renumber selected beams

To renumber the currently selected members, use the following procedure.

1. Select the beams to be renumbered.
2. On the Geometry ribbon tab, select the Renumber Beams tool in the Beam group.

A message dialog opens to warn you that renumbering may not be undone.

3. Click Yes to confirm you wish to proceed.
   The Renumber dialog opens.

4. (Optional) Specify a Start number from
5. (Optional) Select the New Numbering Order
6. (Optional) Select the sort criteria to be used and add them to the Selected Sort Criteria
7. (Optional) Reorder the items in the Selected Sort Criteria
   For example, select the Z Coordinate and click Move Up twice so the order from top to bottom is: Z Coordinate, X Coordinate, Y Coordinate. This instructs the program to renumber beams parallel to the Y axis until no more beams are in that line. It then skips to the next selected entity along the X axis and renumbers those, again along the Y axis. Once it has reached the end of selected beams parallel to the X axis, it then skips to the next selected entity parallel to the Z axis and repeats the previous procedures.
8. Click Accept.
   A message dialog opens with the status of the renumbering operation.
9. Click OK to dismiss the message dialog.
   The selected beams are renumbered following the indicated pattern.

- Renumber dialog (on page 2904)

M. Physical Members

Physical members are composites of one or more analytical members which represent the true physical geometry of a member in a structure.

Note: Physical members use the nomenclature PMEMBER in the STAAD input file.

About Physical Members

Beam objects connecting two nodes in a structural model are referred to as analytical beams as they are the fundamental, one-dimensional object processed by the STAAD engine during analysis. While necessary for this
purpose, they are often difficult elements to use for design as they do not possess the same geometry of a 
physical structural element. For example, a girder is not physically broken where a beam frames, but a node 
must be placed to represent the connection in the model. The design of this girder is then complicated as the 
bracing conditions and other parameters of design can not be directly interpreted by the program.

In this case, STAAD.Pro has the facility to use group one or more analytical beam objects into physical members 
for the purpose of design. This concept is used in both the Steel Design and Concrete Design workflows. 
Additionally, physical members can be created in the modeling mode for the purpose of integrated steel design.

Related Links
- TR.16.2 Physical Members (on page 2443)
- M. To assign catalog section to physical members (on page 742)

M. To manually form physical members

To form a physical member for a selected set of analytical members, use the following procedure.

The following are required to form a physical member:
- analytical members must be interconnected
- analytical members are collinear
- the local axes of the component members should be identical (i.e., the x, y, and z are respectively parallel and 
in the same sense)
- a single analytical member may not be in more than one physical member

1. Select one or more beams which represent a single physical member.

   **Note:** Component analytical members must meet the criteria for physical members.

2. Either
   - on the **Beam** ribbon tab, select the **Form Member** tool in the **Model** group
   - or
   - on the **Geometry** ribbon tab, select the **Form Member** tool in the **Physical Member** group (Analytical 
   Modeling workflow)
   - or
   - on the **Member Design** ribbon tab, select the **Form Member** tool in the **Physical Member** group (Steel 
   Design workflow)
   - or
   - right-click and select **Form Member** from the pop-up menu.

The physical member (i.e., M#) number is displayed on each component analytical member and the physical 
member is added to the **Physical Member** table.
M. To automatically form physical members

To have the program automatically detect and form physical members within a selected set of members, use the following procedure.

1. Select a set of beams that you want formed into physical members.
2. Either:
   - on the Geometry ribbon tab, select the AutoForm Member tool in the Physical Members group (Analytical Modeling workflow)
   
   ![AutoForm Member Tool](image)

   or
   
   - on the Member Design ribbon tab, select the AutoForm Member tool in the Physical Members group (Steel Design workflow)

The program applies the rules of forming physical members to detect which members should be grouped to a single physical member.

M. To automatically generate physical member restraints

Use the following procedure to automatically generate top and bottom flange restraint conditions for the selected physical members.

**Note:** The PBRACE command generated by this menu item is valid only for [AS 4100 (Australian) steel design](on page 1649).

1. Create a STAAD.Pro model with steel members.
2. Either:
   - on the Analysis and Design ribbon tab, select the Design > Steel Design tool in the Design group
   or
   - select the Design page

   The Steel Design - Whole Structure dialog opens.

3. Form one or more physical members in the model.
4. Select AS4100 as the Current Code.
5. Select one or more of the physical members.
6. On the Utilities ribbon tab, select the Physical Member Restraints tool in the Geometry Tools group.

   The PBRACE commands are added for the current design parameter set with the tag (Physical).

   **Note:** Only top or bottom flange restraints can be described using a single PBRACE command. Therefore, this command generates to lines of PBRACE commands for each physical member.
M. To manually add physical member restraints

To manually add physical member restraints for assignment to physical members, use the following procedure. Manual restraints apply to steel physical members which will be designed per AS 4100.

**Tip:** The restraint details can be automatically generated using a new **Member Restraints** item found in the **Utilities** ribbon tab in the **Geometry Tools** group.

1. In the Analytical Modeling workflow page controls, select the Design page.
2. Select **AS4100** as the **Current Code** in the **Steel Design - Whole Structure** dialog.
3. Click **Define Parameters**.
   - The **Design Parameters** dialog opens.
4. Select the **PBRACE** parameter.
5. For each brace point, specify a fraction of the total physical member length in the **Brace Location** cell.

![Edit Design Parameter](image)

6. Select the type of restraint present for the top or bottom flange.
Only top or bottom flange restraints can be described using a single \texttt{PBRACE} command. If both top and bottom bracing is added in the Design Parameters dialog, this will generate two new command lines in the input file.

7. Click \texttt{Add}.
   The new command appears in the tree as a child element of the current design parameter set.

8. Click \texttt{Close}.
   The design parameters are marked with an \texttt{?} icon. This indicates that the need to be assigned to members.

9. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

The \texttt{PBRACE} specification is tagged as (Physical), and therefore can only be assigned to physical members (\texttt{PMEMBER} groups).

**Related Links**

- \textit{D2.B.12.6 Physical Member Restraints Specification} (on page 1653)

**M. To delete a physical member**

1. Select the \textbf{Member Number ID} or any component Beam Number ID in the \textbf{Physical Member Table}.
2. Right click to display the pop-up menu.
3. Select \texttt{Delete}.
   A confirmation dialog opens.
4. Select \texttt{Yes}.

   \textbf{Note}: Only the physical member group assignment is removed. The component analytical beams are not deleted.

   \textbf{Caution}: This cannot be undone.

**M. Plates**

**M. To set new plate attributes**

To specify a set of attributes to automatically assign to new beams, use the following procedure.

1. On the \textbf{Geometry} ribbon tab, select the \texttt{Add Plate > Set New Plate Attributes} tool in the \textbf{Plate} group. The \textbf{Define Plate Object Property} dialog opens.
2. Select the check box for each of the plate object properties you want to use and then select the property value you want to use from the drop-down list:

   \begin{tabular}{|l|l|}
   \hline
   \textbf{Option} & \textbf{Description} \\
   \hline
   \textbf{Property} & Check the \textbf{Use Property} option and then select a defined plate or surface thickness property from the drop-down list. \\
   \textbf{Material} & Check the \textbf{Use Material} option and then select a material definition name from the drop-down list. \\
   \textbf{Release} & Check the \textbf{Use Release} option and then select a plate release specification from the drop-down list. \\
   \hline
   \end{tabular}
3. (Optional) To create a new specification to use, click the associated Create button with the use option checked.
   The corresponding dialog opens to add a property, material, or release. Once you add this specification, the new specification is available from that drop-down list for use.
4. Check the option to Assign these attribute when creating new plates.
5. Click OK.

Related Links
• Define Plate Object Property dialog (on page 2916)

M. To draw plates connecting existing nodes

To draw triangular or quadrilateral plate elements connecting existing nodes, use the following procedure.
This procedure is used to manually add plate elements to your model. STAAD.Pro also has tools to automatically generate a finite element mesh with a surface area.

1. On the Geometry ribbon tab, select one of the following tools in the Plates group:
   Use this tool... To...
   Add Quad Plate create four-node plate elements
   Add Triangle Plate create three-node plate elements

The mouse pointer changes to either the Add Quad Plate cursor ( ) or Add Triangle Plate cursor ( ), respectively.
2. Click on any node that will form the first corner of the plate element.
   A line is “rubber banded” to the cursor from this node. This represents the first edge of the surface.
3. Click on the subsequent nodes to form the plate vertices in either a clockwise or counterclockwise order.
   The plate shape is “rubber banded” to the cursor as you move the mouse pointer to give you a preview of the plate shape.

   Note: Plate vertices should lie within a flat plane. Refer to “ M. To check for warped plates (on page 887)” to verify that plates are planar.

   The plate is added to the model.
4. Repeat steps 2 and 3 to add more plates.
5. To stop adding plates:
   press <Esc>
   or
select any tool

**Related Links**
- *TR.13.1 Plate and Shell Element Incidence Specification* (on page 2431)

**M. To add a plate bounded by beams**

To create an “infill” plate by selecting exiting members as plate edges, use the following procedure.

**Note:** The beams to be used as bounding edges of an “infill” plate must meet the following requirements:
- three or four beams that form a closed polygon
- the beams cannot extend past the vertex nodes of the closed polygon
- the beams must lie within a plane

<table>
<thead>
<tr>
<th>1. Select the beams you want to use as bounding edges of the plate. You must select three or more beams.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> Use the <strong>Beam Cursor</strong> tool in the <strong>Selection</strong> group on the <strong>Geometry</strong> ribbon tab.</td>
</tr>
<tr>
<td>2. On the Geometry ribbon tab, select the <strong>Add Plate &gt; Create Infill Plates</strong> tool in the <strong>Plates</strong> group.</td>
</tr>
</tbody>
</table>

A message dialog indicates that the plate was successfully generated.

**M. To generate plate mesh from corner nodes**

To generate a finite element mesh by selecting corner nodes, use the following procedure.

You must have three or more existing nodes that lie in a plane in your analytical model.

This procedure is used to immediately generate a mesh within a selection of vertices. If you would like to investigate changing parameters prior to generating a mesh or to add openings with the mesh, then you may want to use the procedure a *parametric mesh model* (on page 656) instead.

<table>
<thead>
<tr>
<th>1. On the <strong>Geometry</strong> ribbon tab, select the <strong>Generate Mesh &gt; Create Mesh</strong> tool in the <strong>Plate</strong> group.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The mouse pointer changes to a mesh cursor.</td>
</tr>
<tr>
<td>2. Click the nodes that will form the vertices of the mesh area, in either a clockwise or counter clockwise order.</td>
</tr>
</tbody>
</table>

**Notes:**
- The order of the nodes should be in either a clockwise or counterclockwise direction.
- The nodes must for a polygonal area (i.e., they edges cannot cross).
- The nodes must lie in the same plane.

| 3. When you have select the corner nodes, either: |
select the first node again
or
press <Esc>
The Choose Meshing Type dialog opens.

4. Select the type of meshing to use and then click OK

   **Polygonal Meshing**    Only triangular elements will be created
   **Quadrilateral Meshing** This will create principally four sided elements, but where the geometry dictates, some places may require triangular elements.

   The Define Mesh Region dialog opens.

5. Review the mesh vertices:
   a. Click the Add New Row tool to add a new vertex.
   b. Click the Delete Row tool to remove the currently selected row.
   c. Select the Holes tree entry to add openings to the mesh.

6. Click OK.
The specified area within the vertices is meshed.

M. Parametric Models

STAAD.Pro allows you to model surfaces by automatically generating a mesh from a set of parameters. You can preview the final meshed state of the wall, slab, or panel before deploying the meshed entity into the remainder of the model. This way you can visually examine several trials or prototypes to find the most suitable alternative.

**Tip:** In past versions of STAAD.Pro, facilities for mesh generation have been available through the Geometry menu of the main program window and through the Structure Wizard utility which too is accessible through the Geometry menu. While these facilities continue to be available, an enhanced mesh generation tool has been added to the Geometry page.

This method offers some advantages over other methods of mesh generation in STAAD.Pro:

a. It enables you to preview the final meshed state of the wall, slab or panel before deploying the meshed entity into the remainder of the model. Several trials or prototypes can visually examined before committing to the most suitable one. This greatly minimizes the inconvenience of ending up with an undesirable meshed panel.

b. During the process of meshing, the program will automatically take into consideration existing nodes that lie within the boundary of the panel, but are not chosen as corner nodes of the panel. You simply have to define the panel boundary. The remainder of the nodes will be automatically considered by the program as “control
For generating a finite element mesh, use the following procedure.

1. Select the **Parametric Models** tool in the Plate group on the **Geometry** ribbon tab.

The **Parametric Models** dialog opens. The structure is displayed as a series of dashed lines to signify this mode can be used to experiment with various settings.

2. Click **Add** in the **Parametric Models** dialog.

The **New Mesh Model** dialog opens.

3. Enter a name for the new model (or accept the default).

4. Click **OK**.

The mouse pointer changes to the add surface cursor.

5. Click on the points that form the corners of the panel boundary.

**Note:** Click the points in either a clockwise or counter-clockwise order.

**Tip:** If left the option selected for including nodes and beams in the boundary area, then you can skip over intermediate points lying and a straight line segment, as the program will detect these and add them as mesh nodes automatically.

When the first point is clicked a second time to close the loop, the **Mesh Parameters** dialog opens.

6. Specify the desired meshing parameters and click **OK**.

A dialog opens asking if you wish to add openings to the mesh.

7. (Optional) Click **Yes**

You are asked if the opening is rectangular or circular. Select an option and click the **OK** button to draw the opening on the meshed surface. Refer to the following tasks for additional information on adding openings.

**Tip:** Openings can be added later if needed by clicking the **No** button when asked to add these.

The new mesh model is displayed as an overlay on the structure with control points highlighted. The details of the mesh parameters are available in the Parametric Models dialog.

**Note:** You may edit and refine your mesh by varying the parameters as necessary until the resulting finite element is satisfactory for your model requirements.
8. Once you are satisfied with the surface mesh, click **Merge Mesh** in the Parametric Models dialog to commit it to the STAAD.Pro input file.

**Tip:** To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.

**Related Links**
- Parametric Models dialog (on page 2910)
- Mesh Parameters dialog (on page 2912)
- New Mesh Model dialog (on page 2912)

**M. To create a polygonal opening in a mesh model**

1. In the **Parametric Models** dialog Mesh Models list, select the leaf called **Openings** under the mesh model to which you wish to add an opening.
2. Click **Add**.
   - The Select Opening Type dialog opens.

3. Select the **Polygonal Opening** option and then click **OK**
   - The drawing will change to display just the mesh region. The right hand side of the screen will display a grid with the grid line settings and spacing.
   **Tip:** The various viewing options and zoom options on top of the screen can be used to obtain a convenient view of the panel.
4. (Optional) Edit the grid positions using the **Snap Node/Panel**
5. Click the points inside the panel to define the corners of the polygonal hole.
   **Note:** The cursor displays a blinking cross (+) at grid intersections. This blinking cross marks the point on the grid at which nodes of the hole boundary may be set. Click points around the mesh boundary in either a clockwise or counter-clockwise order, clicking on the first point a second time to close the loop.
   - The mesh is regenerated taking into consideration the hole.
   **Tip:** To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.
M. To create a circular opening in a mesh model

**Note:** In case an opening is required on a part of the structure that is already meshed with plate elements, the existing plates have to be deleted first, and then, the plates with the opening can be modeled as a whole using this feature.

1. In the **Parametric Models** dialog Mesh Models list, select the leaf called **Openings** under the mesh model to which you wish to add an opening.
2. Click **Add**.

   The **Select Opening Type** dialog opens.

3. Select the **Circular Opening** option and then click **OK**.

   The drawing will change to display just the mesh region. The right hand side of the screen will display a grid with the grid line settings and spacing.

   **Tip:** The various viewing options and zoom options on top of the screen can be used to obtain a convenient view of the panel.

4. (Optional) Edit the grid positions using the **Snap Node/Panel**.

5. Click the point which will be the center of the circular opening.

   The cursor displays a blinking cross (+) at grid intersections. This blinking cross marks the point on the grid at which nodes of the hole boundary may be set.

6. Click a second point to define the radius of the circle.

   A dialog opens for defining the number of divisions around the circular opening.

7. (Optional) Change the number of divisions used around the circumference of the circular opening.

8. Click the **OK** button.

   The mesh is regenerated taking into consideration the hole.

   **Tip:** To delete a parametric mesh, opening, density line, or density point, select that entry within the **Parametric Models** dialog and click **Delete**.

M. To add a density line or point

1. In the Parametric Models dialog Mesh Models list, click on the leaf called **Density Lines** or **Density Points** under the mesh model to which you wish to add an opening.

2. Click **Add**.

   The drawing will change to display just the mesh region. The right hand side of the screen will display a grid with the grid line settings and spacing.
Tip: The various viewing options and zoom options on top of the screen can be used to obtain a convenient view of the panel.

3. (Optional) Edit the grid positions using the Snap Node/Panel
4. Either:
   Click the start and points of a density line.
   or
   Click a density point.
   The mesh is regenerated to account for the new density line or point
5. Repeat step 4 as many times as needed.
6. To stop adding density points or density lines, press the <Esc> key.

Tip: To delete a parametric mesh, opening, density line, or density point, select that entry within the Parametric Models dialog and click Delete.

**M. To define a slab/wall connection**

Use the following procedure to generate a mesh for a wall super-element when compatibility with a connected slab super-element is required.

A slab mesh must first be created. The slab mesh should include a density line representing the connecting edge of the wall.

Tip: Using beam elements is fast way to help generate meshed surfaces and ensure that the density line edge for the slab/wall connection is included when the slab is generated. These "construction" beams can be deleted once the surface elements have been successfully generated.

1. On the Geometry ribbon tab, select the Generate Slab/Wall Connection tool in the Structure group.

2. In the Active view window, click the corner nodes of the wall super-element in either a clockwise or counterclockwise order.

   **Note:** The first and second nodes must be the corner nodes which form the slab/wall connection. Failure to do so will open a warning dialog.

3. Continue clicking the remaining corner nodes to for the wall super-element. Close the polygon by clicking on the first node again.

   The Division Along Wall dialog opens.

   **Note:** The divisions along the horizontal side of the wall have already been decided as the number of points created along the wall base in the previously mesh slab.

4. (Optional) Specify a No. of divisions in extrusion direction
**Note:** The divisions along the horizontal side of the wall have already been decided as the number of points created along the wall base in the previously mesh slab.

5. Click **OK**  
The wall is meshed.

**Tip:** To verify the compatibility between plates, select the **Plate Tools > Check Improperly Connected Plates** tool in the **Geometry Tools** on the **Utilities** ribbon tab.

**M. Advanced Surface Mesher**

A preprocessing module for creating finite element meshed surfaces for use with the analysis and design program STAAD.Pro.

**M. To launch the Advanced Mesher program**

1. Either:
   - In the **Bentley Engineering** program group on the Windows **Start** menu, click the **Mesher** icon.
   - or
   - In Windows Explorer, double-click a **SurMesh** file icon (file extension .smh).
   - or
   - Drag an .smh file icon from Windows Explorer and drop it on the **Mesher** icon.
   - or
   - In Windows Explorer, double-click the icon for the program file, **SurMesh.exe**. This file can be located in C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\Mesher in a typical STAAD.Pro installation.

**M. Basics**

Surfaces are created by specifying an external contour, which can be perforated by one or more openings. You can define locations that require specific node positions, such as column positions and areas of higher mesh density. You then select the meshing routine to use and the Advanced Surface Mesher will create a meshed surface that can be refined further and transferred to STAAD.Pro for inclusion in a STAAD.Pro structure.

**M. Example**

Use this procedure to create an example meshed solid which can then be analyzed in STAAD.Pro.
This tutorial utilizes the basic features of the program in order to familiarize you with the process of creating a simple model. Not all tools or options are presented here.

1. Select the **New** tool on the Model toolbar
   An empty file is opened.
2. Select the **Overall Dimensions** tool.
   The Overall dimension dialog opens.
3. Specify a **Width** of 40 m and **Height** of 40 m and then click **OK**.
   Leave the plane as XZ.
   The dimension limits are drawn in the View window.
4. Select the **Grid Options** tool.
   The Grid settings dialog opens.
5. Specify an X spacing of 5 m and a Z spacing of 5 m and then click **OK**.
   The drawing grid is displayed inside the overall dimensions within the View window.
6. If the **Snap to Grid** tool is not set, do so.

   **Tip:** When a tool is set, its icon is shown as depressed in the toolbar and in the menu.

7. Select the **External Contour** tool and click any vertex point as shown in the following figure and table.

<table>
<thead>
<tr>
<th>X (m)</th>
<th>Z (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>35</td>
<td>5</td>
</tr>
<tr>
<td>35</td>
<td>35</td>
</tr>
<tr>
<td>15</td>
<td>35</td>
</tr>
<tr>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>5</td>
<td>20</td>
</tr>
</tbody>
</table>

*Figure 98: External contour*
8. Continue clicking adjacent vertex points in either clockwise or counterclockwise order until the rubber-banded shape looks like the final shape desired; then double-click the final vertex point.

**Tip:** You can right-click to undo the previous data point if necessary.

The external contour shape is shaded gray.

9. Select the Internal Contour tool and click any vertex point of the opening shown in the following figure and table.

![Figure 99: Opening in the surface](image)

<table>
<thead>
<tr>
<th>X (m)</th>
<th>Z (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>10</td>
</tr>
<tr>
<td>30</td>
<td>10</td>
</tr>
<tr>
<td>30</td>
<td>30</td>
</tr>
<tr>
<td>25</td>
<td>30</td>
</tr>
<tr>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>5</td>
<td>20</td>
</tr>
</tbody>
</table>

10. Continue clicking adjacent vertex points in either a clockwise or counterclockwise order until the rubber-banded shape looks like the final shape desired; then double-click the final vertex point. The shading is removed inside the inner contour shape to represent the opening.

**M. Technical Reference**

This section details the engineering theory and methods behind the program.

The Advanced Mesher uses the Delanay meshing principles to create a triangular mesh using vertices and density settings specified by the user. The basic Delanay routine can be modified by three options known as the Triangulation Methods. On top of this there is an additional Parallel Grid quad option that can be used on surfaces that are defined with edges between vertices that lie purely in the X and Z axes.
**Triangulation Methods**

The Advanced Mesher uses three types of meshing routines:

1. Triangulation using the defined vertices only
2. Triangulation without sub-dividing the contours, but creating additional internal elements.
3. Triangulation sub-dividing the contours as well as creating internal elements.

Method A) uses the Delaunay triangulation – DT.

Methods B) and C) use the constrained Delaunay triangulation – CDT on PSLG (planar straight line graph).

The points created by the meshing routine that were not defined by the user in methods B) and C) are referred to as Steiner points or Free Nodes. When creating the triangles in method B) and C) the program ensures that only acute angles or obtuse angles are created in the mesh. Additionally, with method C) the user specified triangulation step is used to limit the maximum length of the side of a triangle or the area of the triangle. Note that there is a direct relationship between the length of the longest side of a triangle and its area.

**Definitions**

- **height**: the maximum distance to a vertex from a longest edge.
- **aspect ratio**: the ratio of the longest length to its height.
- **u**: the minimum internal angle.

Therefore, the aspect ratio \( > \frac{1}{\sin(u)} \) and \( \leq \frac{2}{\sin(u)} \)

Also if the step \( \leq L \), Area of triangle \( \leq \frac{L^2}{4 \sin(u)} \)

![Figure 100: Triangle element nomenclature](image)

**triangulation density**

Defined for each triangulation vertex. The triangulation density is the ratio between the maximum length of the lines emanating from the vertex, to the triangulation step. Where the length has been limited by the triangle area (or length), then the triangulation density of a given vertex is the ratio of the area of the largest triangle connected to the vertex to the triangulation parameter. Therefore, the triangulation density never exceeds one (unity).

Note that the program allows the user to specify triangulation density for:

- **a.** Nodes (thickening nodes)
- **b.** Lines (thickening lines), specified density applies to all vertices along the line.
- **c.** Regions (thickening region), specified density applies to all vertices that occur within the region including the edge.

**Note:** Also, if a vertex is covered by more than one density setting — such as a density line and a density region — then the maximum density setting will be used for either situation.
The formation of triangles

Consider the following plane surface with an internal opening shown in the following figure. It is defined by two contours, an external and a single internal contour. Straight lines between vertices define the contours. Vertices of contours are indicated with a red circle.

![Figure 101: Plan surface with opening](image1)

Triangulation is defined as the representation of the plane surface with a set of united, inter-connected (i.e., sharing edges), but not overlapping triangles.

![Figure 102: Simple triangulation](image2)

The vertices of the triangles are referred to as triangulation nodes. In the above simple triangulation, only the vertices defined by the contours are used. However, you can specify additional nodes inside the surface as shown in the following figure. The supplementary triangulations nodes assigned are indicated with a cyan circle.
If you choose Triangulation Method B) or C), then additional nodes may be generated by the program. These nodes are known as Steiner’s points, or free nodes, and are indicated in the following figure with a magenta circle.

![Triangulation with intermediate nodes](image1)

*Figure 103: Triangulation with intermediate nodes*

After the initial meshing process, these free nodes can be modified to suite a specific requirement such as maximising the minimum angle on the triangles, using the Smoothing tool.

**M. Technical Notes**

Aspect Ratio, Triangulation Step, and Area Limitation

![Aspect Ratio Diagram](image2)

The aspect ratio (AR) is defined as:
\[ AR = \frac{L_1 + L_2}{h} = \frac{1}{\tan(\theta)} + \frac{1}{\tan(\alpha)} \geq \frac{2}{\tan(\theta)} = \frac{2 \cos(\theta)}{\sin(\theta)} \geq \frac{1}{\sin(\theta)} \]

Of the two angles shown the diagram, \( a^2 q \) and monotonic decrease of function \( 1/\tan \) are used here. In addition, since angle \( q \) is the minimum, therefore \( 2\cos(q)^2 \)

By analogy:

\[ AR = \frac{L_1 + L_2}{h} = \frac{1}{\tan(\theta)} + \frac{1}{\tan(\alpha)} = \frac{\sin(\theta + \alpha)}{\sin(\theta)\sin(\alpha)} \leq \frac{\sin(\theta)\cos(\theta) + \cos(\theta)\sin(\alpha)}{\sin(\theta)\sin(\alpha)} \]

It means that to prove the above estimation it is necessary to demonstrate that

Since \( 90^o a^2 q \), then

It remains to note, that .

Since area of a triangle is equal to \((L_1+L_2)/2\) then it leads to, that is the above estimation for area, when angle \( q \) is constrained from below, results in to the above estimation of triangulation step.

Moreover, instead of estimation using the more accurate estimation we obtain

Jacobian

\[ \begin{align*}
\text{Coordinate element} & \quad W \\
\text{Ideal element} & \quad AW^{-1} \\
\text{Real element} & 
\end{align*} \]

Matrix \( A \) (referred to as the Jacobian matrix) transfers points of the coordinate triangle to the real triangle. Matrix \( W \) transforms coordinate triangle into equilateral (ideal) triangle. Therefore matrix \( S = AW^{-1} \), which transforms ideal element into real one, defines deviation of real element from ideal one.

For any triangle, the free vertex which is located at the point \( x \), and two other vertices \(- xi, xj \), the Jacobian is equal to

\[ \det (xi - x, xj - x) \]

Algorithms Used

A - triangulation - is a classical Delaunay triangulation (see, for example, [9]). For other cases a version of J.Rupert [2] algorithm is used.

Smoothening

Basic smoothening algorithm is described in reference [10].

Laplace

Node is moved to the point, which is averaging of locations \( M \) of the nearest nodes

\[ x_n = \frac{1}{M} \sum_{m=0}^{M-1} x_m \]

<tr>
<td>Projection Upon the XY Plane</td>
<td>Rotates the view of the surface model to display it in the X-Y plane (i.e., the front elevation).</td>
</tr>
<tr>
<td>Export</td>
<td>Opens the Export dialog, which is used to specify a file name an location for a STAAD.Pro Input file (file extension .STD) so the current surface mesh can be analyzed using STAAD.Pro.</td>
</tr>
</tbody>
</table>

**M. Triangulation dialog**

Used to specify the meshing method and associated parameters for meshing.

Opens when Edit > Triangulation is selected.

Dialog controls

**Mesh Type**

If methods B) or C) are selected, the option to limit the element size become available. This determines the size of the longest edge of the elements that are to be generated.
Element Size
Specify a target element size in the current units.

Element Type
There are four element types:
· Triangular
· Quads from Merged Triangles
· Quads (from Breaking of Triangles)
· Parallel Grid Quads.

Quads from Merged Triangles
Quads (from Breaking of Triangles)

Additional Boundary Nodes
Instructs the program to use

Cancel
Closes the dialog without generating a mesh for the surface.

OK
Closes the dialog and generates a mesh with the selected parameters for the surface.

M. Smoothing dialog
Used to improve the mesh quality by selecting a criteria and number of times that criteria is repeated.

Opens when Edit > Smoothing is selected.

Dialog controls
Smoothing criteria

Number of iteration
Specify a number of times the criteria is to be repeated.

OK
Adds the selected smoothing criteria and closes the dialog.

Cancel
Closes the dialog without adding any smoothing criteria.

M. Mesh Quality dialog
Used to visualize an aspect of the mesh by color coding to evaluate the mesh quality.

Opens when Edit > Mesh Quality is selected.

Dialog controls
The options that are available are:-
· Aspect Ratio Gamma
· Element Area
· Minimum Angle
· Maximum Angle
· Scaled Jacobean
· Ratio of Maximum to Minimum Angles
· Ratio of Maximum to Minimum Edge Length
· Ratio of Triangle Area to the Maximum Area of Connected Triangles
· Ratio of Triangle Area to the Minimum Area of Connected Triangles
· Ratio of the Area to the Square of the Perimeter
· Skew
· Taper
· Stretch
· Oddy
· Jacobean
· Warpage

Note that some of these options are available for triangular or quadrilateral elements only.

The selected item is then divided into a range of between 2 and 16 bands from the minimum to the maximum value. The number and default boundaries can be modified by the user if required.

These defined boundaries are then shown in a table which are colour coded with one of the following colour scales:-

From pale yellow to red
From blue to red
From light grey to black
Multicoloured spectrum

It is additionally possible to select only a range of values to display by having a tick against only those range values that are required. Click on the Turn OFF button to turn all the values off and click on those that are required. Click on the Turn ON button to turn on all the values and click off those values that are not required.

To view the values of the chosen parameter on the elements, click on the Digitize icon on the toolbar.

OK Closes the dialog and opens the Triangle Quality dialog with the range and interval options for the selected mesh criteria. Click OK to display the results graphically on the surface.

Cancel Closes the dialog without selecting a mesh quality criteria.

M. Settings menu
Contains items for controlling non-element specific settings as well as the behavior and display of the drawing environment.

Contains several of the most commonly used tools found in the Advanced Surface Mesher module Triangulation mode.
<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
<th>Same effect as selecting …</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1" alt="Tool" /></td>
<td><strong>Create density points on the contours</strong></td>
<td>Used to add triangulation points on external or internal contour lines. As with the vertices for the contours, nodes for the triangulation will always be generated on these points. Density Points are displayed with a red dot. <strong>Note:</strong> If a vertex at either end of the line is moved, then the density point will be moved in such a way so that the point will remain in the same proportion along the line defined by the new vertices</td>
</tr>
<tr>
<td><img src="image2" alt="Tool" /></td>
<td><strong>Mark nodes as density points</strong></td>
<td>Used to modify the density around a selected vertex. Once selected, a method of vertex selection must be activated from the status bar.</td>
</tr>
<tr>
<td><img src="image3" alt="Tool" /></td>
<td><strong>Create density points inside</strong></td>
<td>Used to define density points inside the external contour. Density Points are displayed with a red dot. <strong>Note:</strong> If the Snap to Grid option is active, then the density point will be added to the nearest grid intersection.</td>
</tr>
<tr>
<td><img src="image4" alt="Tool" /></td>
<td><strong>Delete density points</strong></td>
<td>Used to remove any density settings on nodes and remove density points on lines or inside entirely.</td>
</tr>
<tr>
<td><img src="image5" alt="Tool" /></td>
<td><strong>Internal density lines</strong></td>
<td>Used to specify density lines within the envelope defined by the external contour. Density lines are displayed in green.</td>
</tr>
<tr>
<td>Tool</td>
<td>Description</td>
<td>Same effect as selecting …</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td><img src="image" alt="Border density lines" /></td>
<td>Used to specify the density setting along an external or internal contour. <strong>Note:</strong> Border Density Lines cannot be applied to lines that have had Density Points on Lines applied or already have had a Border Density setting applied. These should be removed and the new Border Density setting applied.</td>
<td></td>
</tr>
<tr>
<td><img src="image" alt="Crack lines" /></td>
<td>Used to add crack lines to the surface model.</td>
<td></td>

### M. Composite Decks

STAAD.Pro can model composite steel deck systems for design.

An important feature to note is that when the structure is modified, the deck automatically gets modified with it. Note that when the dimension of the structure is changed along the length from 30 ft to 40 ft, the deck gets modified with the structure and there is no need to redefine the deck all over again. The deck loading is also revised automatically.

![Figure 106: Composite deck and load update with structure changes](image)

The design parameters for the composite deck are already defined through the interface. Few additional design parameters like TRACK can be assigned, if so desired, and finally, design commands like CHECK CODE has to be assigned to the composite deck.

### Related Links

- [Composite Deck dialog](on page 2916)
- [TR.20.7 Composite Decks](on page 2473)
- [M. To add a floor load or one-way load](on page 831)
M. To create a new composite deck from perimeter beams

1. Select the **Composite Deck Layout** tool in the **Composite Deck** group on the **Geometry** ribbon tab.

   The **Composite Deck** dialog opens.

2. Select the perimeter beams:
   a. Select the **Clicking on Nodes** option.
   b. Click **Create New Deck**.

   The mouse pointer changes to the Add Composite Deck cursor ( ).
   c. Click on the end nodes defining the corners of the perimeter beam area.
   d. Click on the first node a second time to close the decking area.

   Alternatively, you can select the perimeter beams in the view window first. Then select the **Use Selected Beam** option and click **Create New Deck**.

   The **New Composite Deck** dialog opens.

3. Type a **New Composite Deck Name** and then click **OK**.

   The deck name is added to the list of composite decks with all the perimeter and interior beams listed.

   **Note:** You can delete a composite deck definition by selecting it in within the list in the **Composite Deck** dialog and then pressing **<Delete>**. Confirm you want to delete the deck in the dialog. Only the deck definition is deleted. Constituent members will remain in the model.

**Related Links**
- **Composite Deck dialog** (on page 2916)

M. To specify a direction for the composite deck ribs

To specify the orientation of the deck ribs, use the following procedure.

The program will automatically assign a rib direction parallel to the detected shortest span in the deck area. However, you will often need to edit the orientation.

1. Select a composite deck name in the **Composite Deck** dialog list.
2. Select a pair of parallel beams.

   The deck ribs will run perpendicular to these two beams.

3. Click **Create Direction**.

   If you have previously assigned a deck rib direction, you will be prompted to confirm you want to update this direction.

   The deck span direction arrow is updated to reflect the change in direction.

**Related Links**
- **Composite Deck dialog** (on page 2916)
M. To assign composite deck properties

To define the concrete, rib, and connectivity details of a composite deck, use the following procedure.

1. Select a composite deck name in the Composite Deck dialog list.
2. Type values to use for the concrete in the current units:
   - Concrete thickness above flutes
   - Unit Wt. of Concrete
   - Concrete Grade
3. Specify the steel deck rib properties:
   - To...                        Do the following...
     use a catalog value          select the deck name from the Use Database drop-down list
     specify a custom value       type values for Rib Width and Rib Height.

   Note: The program includes three standard catalogs: ASC™, Vulcraft™, and VERCO™.

4. Specify the Stud Diameter by either:
   - selecting a predefined diameter from the drop-down list
   - or selecting Custom in the drop-down list and then typing the diameter in the current units
5. Type the Stud Length in the current units.
6. Select if the composite deck is Shored (i.e., propped) or Unshored during construction.
7. Click Update Deck Property.

Related Links
- Composite Deck dialog (on page 2916)

M. To modify composite steel beam properties

To change the steel beam profile or effective flange width, use the following procedure.

The program will use the assigned steel sections for beams and also automatically calculate the effective flange width of the composite section. However, you can update steel sections from the Composite Decks dialog as well as specify a value for the effective flange width.

1. Select a beam in the Composite Decks dialog within a composite deck name.
   The beam options are displayed in the dialog.
2. (Optional) Click Add/Change Property to open the Section Profile Tables dialog.
   From there, you can select a different beam or beam properties.

   Note: You should not specify a composite section type specification for these beams. The use of the composite deck definition allows the program to calculate all the necessary composite section parameters automatically. Refer to G.6.7 Composite Beams and Composite Decks (on page 2328) for details.
3. (Optional) Type an Effective Width in the current units and then click Update to change the effective width of the composite deck for the beam.
M. Solids

M. To draw a solid connecting existing nodes

To draw a solid with 4 to 8 nodes connecting existing nodes, use the following procedure. You model must have at least four nodes which do not all lie in the same plane. The basic solid element consists of 8 nodes. However, by collapsing nodes together progressively, different three-dimensional solid shapes can be formed. The minimal number of nodes is a four-noded, pyramidal shape.

1. On the Geometry ribbon tab, select one of the tools in the Add Solid menu in the Solid group.

   Use this tool...  To...
   
   create eight-noded solid elements (i.e., a cuboid)

   create seven-noded solid elements

   create six-noded solid elements (i.e, a triangular prism)

   create five-noded solid elements (i.e., a rectangular pyramid)

   create four-noded solid elements (i.e., a triangular pyramid, or tetrahedron)

   The mouse pointer changes to either the Add Solid cursor ( ).

2. Click on any node that will form the first corner of the solid element. A line is “rubber banded” to the cursor from this node. This represents the first edge of the solid.

3. Continue clicking on nodes up to the number corresponding to the tool selected in step 1. The solid element is added to the model.

Related Links
M. Nodes

To insert a node in a single member

Used to insert nodes in an existing member(s). The member is split into the corresponding number of segments with automatic generation of node numbers, member numbers, member properties, and loads.

1. On the Geometry ribbon tab, select the Insert Node tool in the Beam group.

   ![Insert Node tool]

   The mouse pointer changes to the Insert Node pointer.

2. Select a beam member.

   The Insert Nodes into Beam # dialog (on page 2906) opens.

3. Either:

   - Specify a Distance or Proportion value and click Add New Point.
   - Click Add Mid Point to add a new node halfway along the length of the beam.
   - Specify an integer number of new nodes in the \( n = \) box and click Add n Points to divide the beam into \( n+1 \) number of equal divisions.

   The new node point is listed in the Insertion Points list.

4. Repeat Step 3 as many times as needed.

   Tip: Click Remove to remove the selected node point from the Insertion Points list if you make an error.

5. Click OK.

   The dialog closes and the specified nodes are inserted into the beam.

Related Links

- Insert Nodes into Beam # dialog (on page 2906)

To insert a node in multiple members

Used to insert nodes in an existing member(s). The member is split into the corresponding number of segments with automatic generation of node numbers, member numbers, member properties, and loads.

1. Select two or more beam elements.

2. On the Geometry ribbon tab, select the Insert Node tool in the Beam group.
The **Insert Node/Nodes** dialog (on page 2907) opens.

3. Either:
   - Select the **New point by distance** option and then type a **Distance** value.
   - or
   - Select the **New point by proportion** option and then type a **Proportion** value.
   - or
   - Select the **Add Mid Point** option.
   - or
   - Select the **Add 'n' Points** option and then type an integer number of new nodes in the \( n = \) box to divide the beam into \( n + 1 \) number of equal divisions.

4. Click **OK**.
   - The dialog closes and the specified nodes are inserted into the beams.

**Related Links**
- **Insert Node / Nodes dialog** (on page 2907)

**M. To add a node at overlapping beams**

To connect to overlapping beams with a node at that location, use the following procedure.

You can manually select beams that are overlapping or the program can automatically detect these for you using the optional first step below.

1. (Optional) Automatically select overlapping beams:
   - a. On the **Geometry** ribbon tab, select the **Intersecting Beams > Highlight Intersecting Beams** tool in the **Beam** group.

   The **Intersect Members** dialog opens.
   - b. In the **Enter Tolerance** field, type a tolerance used for how close members should pass before the program considers them to be overlapping.
   - c. Click **OK**.
   - The program automatically selects all overlapping beam sets.

2. On the **Beam Tools** ribbon tab, select the **Intersect Beams** tool in the **Model** group.

3. Type a tolerance to use in the **Intersect Members** dialog and then click **OK**.
   - A message dialog opens to indicate that new beams have been created.
M. To merge two nodes

1. Select the nodes to be merged using the Nodes Cursor.
2. On the Geometry ribbon tab, select the Merge Selected Nodes tool in the Node group.

The Select Node dialog opens.
3. Select the Node To Keep from the list of selected nodes.
   The remaining nodes will be removed. All members and elements which were connected to those nodes will
   be reconnected to the selected node to keep.
4. Click OK.

M. Modify Your Model

The following procedures are used to manipulate existing model geometry.

M. To move selected objects

You must have one or more objects selected.
Refer to GS. Selecting Objects in STAAD.Pro (on page 37) for details.

1. On the Geometry ribbon tab, select one of the following tools:
   - the Move Node tool in the Node group
   or
   - the Move Beam tool in the Beam group
   or
   - the Move Plate tool in the Plate group
   or
   - the Move Solid tool in the Solid group
   The Move Entities dialog opens.
Note: This dialog has a different title depending on the object type being moved but the functionality is similar.

2. Select the method by which the objects are to be moved:

   By distance between following nodes uses two node numbers and determines the vector between them. The selected entities are moved along a parallel vector of the same distance.

   or

   By the following X, Y and Z values uses the Cartesian coordinates specified to create a vector.

3. Specify node numbers or vector component values.

4. (Optional) Check the Retain connections option to retain connections between entities.

   Note: The model geometry will be adjusted to some degree, even if this is not selected, when nodes are the entities being moved as they member, plate, surface, and solid geometry is defined by node location. However, if you are moving a member, plate, surface, or solid, then selecting this option will move the associated nodes and thus retain the connection with adjacent entities (though their geometry will stretch, warp, or shift as a result of the move).

5. Click OK.

   A message dialog opens asking if you would like new nodes created where any moved entities cross other existing entities.

6. Click Yes to create new nodes or No to ignore intersections.

   The model is updated with the moved geometry.

Related Links

• Move Entities dialog (on page 2902)

M. To move the model origin

To shift the translate the entire model by shifting the origin location along a vector, use the following procedure.

Tip: You can use the Generate Rotate tool to rotate the entire model about the origin as well.

The Move Origin dialog opens.

2. Specify the origin offset vector method:

<table>
<thead>
<tr>
<th>Vector method</th>
<th>Do the following…</th>
</tr>
</thead>
<tbody>
<tr>
<td>two nodes</td>
<td>select the By distance between following two nodes and then type the node numbers in the corresponding fields.</td>
</tr>
<tr>
<td>global axes components</td>
<td>select the By the following X, Y and Z values and then type the global axes component distances in the corresponding fields.</td>
</tr>
</tbody>
</table>

Either method generates a vector by which the origin is shifted.

**Note:** A positive value in the coordinates (or resulting positive value resulting the from the selected nodes) will move the origin in a positive direction along the corresponding global axis. Thus, the resulting coordinate of each node is therefore reduced by that same magnitude.

For example, providing a origin shift along the X axis of 5 units, means that a node previously located at the origin now has an X coordinate of -5 units.

3. Click OK.

The coordinates of each node are modified in the STAAD input file to reflect the change in distance to the new origin.

**Related Links**
- Move Origin dialog (on page 2903)

**M. To rotate selected entities**

You must have one or more objects selected.

Refer to GS. Selecting Objects in STAAD.Pro (on page 37) for details.

1. On the Geometry ribbon tab, select the Rotate tool in the Structure group.

   The Rotate dialog opens.

2. Specify an Angle of rotation.

3. Provide two points used to define the axis of rotation by either:

   - selecting two Nodes
   - or
   - typing coordinates of two arbitrary Points

4. Select if the selected geometry is to be copied or moved and, if copied, if linking members are to be created.

5. Click OK.

**Related Links**
M. To generate copies of geometry along a line

To generate copies of selected geometry along a path parallel to a global axis, use the following procedure.

1. Select the structure geometry (beams, plates, solids, etc.) that you want to copy.

   **Tip:** You do not need to select the nodes, as they will be copied along with the other model entities.

2. On the **Geometry** ribbon tab, select the **Translational Repeat** tool in the **Structure** group.

   The **Translational Repeat** dialog opens.

3. Select the **Global Direction** along which the copies will be generated.

4. Specify the **No. of Steps** to generate.

   **Tip:** By setting the **Default Spacing** value first, the entries will update with the new value for each step.

5. (Optional) Edit the **Spacing** values for each step (copy) if the steps are irregular or if the desired **Default Spacing** was not first specified.

6. (Optional) Set the option to **Renumber Bay** and specify a **Number from** value (start number of that copy) if needed.

7. (Optional) Set the **Link Steps** option to generate additional members between copies, parallel to the **Global Direction**.

   You may also set the **Open Base** option, which will prevent links from being generated between nodes with the lowest Y coordinates (when Y is vertical/up).

8. (Optional) Set the **Generation Flags** to the level of geometry, properties, or specifications to be copied to the new, generated members.

9. Click **OK**.

   The new members are generated using the specified parameters.

**Related Links**

- **Translational Repeat dialog** (on page 2892)

M. To generate copies of geometry along an arc

To create copies of selected geometry along an arc about a global axis, use the following procedure.

1. Select the structure geometry (beams, plates, solids, etc.) that you want to copy.

   **Tip:** You do not need to select the nodes, as they will be copied along with the other model entities.

2. On the **Geometry** ribbon tab, select the **Circular Repeat** tool in the **Structure** group.

   The **3D Circular** dialog opens.
3. Select the global **Axis of Rotation** about which the copies will be generated.

4. Specify the **Total Angle** of the arc.
   
   This is measured in a positive (right-hand rule) direction about the selected **Axis of Rotation** between the original selection and the last copy.

5. Specify the **No. of Steps** to generate.
   
   The copies will be equally distributed about the specified arc.

6. Specify a center of rotation by either:
   
   - typing a Node number. You may also click the Node Selection tool to graphically select a node.
   - or
   
   planar coordinates for an arbitrary point (i.e., not at a node)

   **Note:** The axis of rotation for the circular copy will pass through this selected node or point, parallel to the selected global axis of rotation.

7. (Optional) Check the **Use this as Reference Point for Beta angle generation** option to orient the copies towards the central axis of rotation.

8. (Optional) Set the **Link Steps** option to generate additional members between copies.
   
   You may also set the **Open Base** option, which will prevent links from being generated between nodes with the lowest Y coordinates (when Y is vertical/up).

9. (Optional) Set the **Geometry Only** option to generate only nodes, members, elements, etc. with no properties assigned.

10. Click **OK**.

   The new members are generated using the specified parameters.

**Related Links**

- **3D Circular dialog** (on page 2893)

**M. To generate mirror copies of model entities**

To generate symmetric copies of the model selection about a plane, use the following procedure.

1. Select the geometry to copy or move.

   **Note:** Refer to the discussion on the Select menu for details on the selection procedure.

2. On the **Geometry** ribbon tab, select the **Mirror** tool in the **Structure** group.

   The **Mirror** dialog opens.

3. Specify an mirror plane.

4. Specify a Plane position.

5. Select if the selected geometry is to be copied of moved and, if copied, if linking members are to be created.

6. (Optional) Set the option to mirror members if their orientation is also to be mirrored.

7. Click **OK**.

**Related Links**
M. Groups

A group is a way to collect a series of objects together for selection, loading, or design purposes.

M. To create a group from a selection

To create a new group using a selection of model objects, use the following procedure.

Group names are a means for easily identifying a collection of entities like Beams, Plates or Solids using a single moniker. By grouping these entities, we need to assign attributes such as member properties and material constants just to the group, a simple process, compared to the task of assigning them to the individual members.

The file EX. US-1 Plane Frame with Steel Design (on page 4313) is used to demonstrate this feature.

Consider the members which form the truss as being in one of three groups: Top Chords, Bottom Chords, and Web Members.

1. Select the top chord members:
   With the model open, use the Beam Cursor tool to select the members forming the top chords (i.e., members 8 through 13).

   Tip: Press and hold the <Ctrl> key and then click the members in the View window.

2. Either:
   On the Utilities ribbon tab, select the Groups tool in the Geometry Tools group.
or
press <Ctrl+G>

If you have not previously defined any groups, the Define Group Name dialog opens. Otherwise, the Create Group dialog opens (skip to step 4).

3. Specify the group details:
   a. Type a name in the Group Name field.
      
      Note: Group Names must begin with the underscore "_" character.
      
      A group name such as _TOPCHORD can be used for this example.
   b. Select the object type from the Select Type drop-down list.
      
      Groups can consist of nodes, beams, plates, solids, and a general category called geometry. Geometry can be used to associated objects of mixed types.
      Select Beam for the top chords example.
   c. Click OK.

      The Create Group dialog opens. At this point, you have created a group name but it does not yet contain any objects.
4. Select **Associate to Selected Geometry** and then click **Associate**.

The selected members are added to the group.

5. Select other model objects.

**Tip:** The **Create Group** dialog can remain open while you change selection tools and select objects in the View window.

For the example file, the members forming the bottom chord (members 20, 21, 22, and 23).
6. Associated these members with a new group:
   a. Click **Create** in the **Create Group** dialog.
   b. Follow steps 4 and 5 and assign the **Group Name** and objects type as the **Select Type**.
      For the example file US-1 Plane Frame with Steel Design.std, use the name _BOTCHORD for the bottom chord members.

7. Repeat steps 5 and 6 to create additional groups as needed.
   For the example file US-1 Plane Frame with Steel Design.std, you can select the truss web members (members 14, 15, 16, 17, 18, and 19) and add them to a group named _TRUSSWEB
8. Click Close in the Create Group dialog.

Select the Group Selection tool in the Selection group on the Selection ribbon tab to open the Select Groups dialog, which can be used to select a named group.
Note: If the option for **Show Label** are unchecked, labels such as beam numbers will not be displayed for these specific members, even if the beam numbering icon is switched on for the entire structure.

**Related Links**
- *Create Group dialog* (on page 3099)
- *TR.16.1 Listing of Entities by Specifying Groups* (on page 2440)

**M. To add objects to an existing group**

To add more objects to an existing group, use the following procedure.

It is important to select the current objects in a group along with the additional objects so that the current objects are not removed. When associating objects to a group, *only* the current selection (or other association method) will be included in the group.

1. On the Utilities ribbon tab, select the Groups tool in the Geometry Tools group.

![Create Groups dialog](image)

   The **Create Groups** dialog opens.

2. Select the group name to which you want to add objects.

3. Click **Highlight**.

   The current objects in the group are selected in the view window.

4. In the view window, use the selection cursors to select the additional geometry.

   **Note**: Hold the `<Ctrl>` key in order to select additional objects without unselecting the current group contents.

5. Select the **Associated to Selected Geometry** option.

6. Click **Associate**.
M. Structure Wizard

Used to parametrically generate a structural model and then transfer and superimpose it on the current structure in STAAD.Pro.

Opens when **Geometry > Run Structure Wizard** is selected in the STAAD.Pro window.

The **Prototype Models** and **Saved User Models** options appear on the top of the left side of the screen. If the **Prototype Models** option is selected, the **Model Type** will list the types of prototype structures available (such as Trusses, Frames, Plates, Solids, etc.) as shown below. If the **Saved User Models** option is selected, the **Model Type** will display the list previously done and saved models by the user.
To set units

To set the units of length used in the parametric model types, use the following procedure.

The current units of length are displayed in the Structure Wizard status bar.

1. Select **File > Select Units**.
   
   The **Select Units** dialog opens

2. Select one of the units of length.
   
   - Inches
   - Feet
   - Millimeters
   - Centimeters
   - Meters

3. Click **OK**

**M. Generation of Structure from Models**

In this section, the process of generating a structural model and combining it with the existing STAAD.Pro structure will be explained using a Howe Roof truss. Follow these steps to create the other truss types also.

**Selection of Units**

The unit of length should be specified prior to the generation of a model. Select **File > Select Unit** and the **Select Unit** dialog opens. You can select any unit of length from Imperial (inch, feet) or SI/Metric (millimeter, centimeter, meter) system of units.
To create a truss model

1. Select **Truss Models** from the **Model Type** drop-down list.
2. Select one of the parametric truss types by either:
   - double-click on the type of model
   - or
   - click-and-drag the model icon into the view window

   - **Pratt Truss**
   - **Warren Truss**
   - **Howe Bridge**
   - **Lattice Truss**
   - **Howe Roof**
   - **North Light**

   The **Select Parameters** dialog opens.

3. (Optional) Type a **Model Name**.
4. Type the overall truss **Length**, **Height**, and **Width** distances.
5. Type the **No. of bays along length** to define the number of equally spaced bay along the length of the truss.
6. (Optional) To use unequaly length bays:
   - a. Click the [...] adjacent to the **No. of bays along length** field.
      A dialog opens with the length of each bay.
b. Type the length of the different bays in the corresponding **Length** cells.

**Note**: The total length of the bays must add to the overall length specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

c. Click **OK**.

**7.** Type the **No. of bays along width** to define the number of transverse bays.

**8.** (Optional) To use unequal length transverse bays:
   a. Click the […] adjacent to the **No. of bays along width** field.
      A dialog opens with the length of each bay.
   b. Type the length of the different bays in the corresponding **Length** cells.

**Note**: The total length of the bays must add to the overall width specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

c. Click **OK**.

**9.** Click **Apply**.

**M. Frame Models**

The process of generating a Frame structural model and combining it with the existing STAAD.Pro structure is the same as for Trusses (see the above description).

**M. To create a frame or continuous beam model**

To create a continuous beam, bay frame, grid frame, or floor grid model, use the following procedure.

**1.** Select **Frame Models** from the **Model Type** drop-down list.

**2.** Select one of the rectangular frame or beam types by either:
   - double-clicking the icon
   - or
   - click-and-drag the icon to the view window

   - **Bay Frame** – a 3D frame with no horizontal connecting members at the base
   - **Grid Frame** – a 3D frame that has horizontal connecting members at all levels
   - **Floor Grid** – a 2D frame in the XZ plane
Continuous Beam – a linear beam continuous over internal supports (i.e., the bay length)

The Select Parameters dialog opens.

3. (Optional) Type a Model Name.
4. Type the overall dimensions of the frame or beam:
   a. Type the Length.
   b. For bay frames and grid frames, type the Height.
   c. For frames, type the Width.
5. Type the number of bays in each dimension:
   a. Type the No of bays along the length.
   b. For bay frames and grid frames, type the No of bays along the height.
   c. For frames, type the No of bays along the width.
6. (Optional) To use unequal length division in any direction:
   a. Click the [...] button adjacent to that field.
      A dialog opens.
   b. Type the length of each bay.
   c. Click OK.

   Note: The total length of the bays must add to the overall length specified in the Select Parameters dialog. The precision should be to about 3 decimal places (e.g., 11.333).
7. Click Apply.

M. To create a cylindrical frame or beam

To create a cylindrical frame or circular beam, use the following procedure.

1. Select Frame Models from the Model Type drop-down list.
2. Select one of the cylindrical frames or beam types by either:
   double-clicking the icon
   or
   click-and-drag the icon to the view window

   Cylindrical Frame — a cylindrical frame with the cylinder height along the Z axis
   Reverse Cylindrical Frame — a cylindrical frame with the cylinder height along the Y axis
   Circular Beam — a single layer of coordinates which form a beam along a circular arc (i.e., polar coordinates)

The Select Parameters dialog opens.
3. (Optional) Type a **Model Name**.
4. For frames, type the total **Length** along the central axis of the cylinder.
5. Type the **Radius** and the sweep **Angle** of the frame.

   **Tip:** For a full circular frame or beam, leave the Angle 360.

6. For frames, type the **No. of bays along length**.
7. (Optional) For frames with irregular spaced bays along the length:
   a. Click the […] button adjacent to the **No. of bays along length** field. A dialog opens.
   b. Type the length of each bay.
   c. Click OK.

   **Note:** The total length of the bays must add to the overall length specified in the **Select Parameters** dialog. The precision should be to about 3 decimal places (e.g., 11.333).

8. Type the **No of bays along periphery** to specify the number of spaces along the circumference of the circle.
9. (Optional) For frames with irregular spaced bays along the length:
   a. Click the […] button adjacent to the **No of bays along periphery** field. A dialog opens.
   b. Type the angle subtended by each bay.
   c. Click OK.

   **Note:** The total of the angles of all the bays must sum to equal the total Angle given in the **Select Parameters** dialog.

10. Click **Apply**.

**M. Surface or Plate Models**

The surfaces like Quadrilateral Plate, Cylindrical Surface, Hyperbolic Paraboloid Shell, Polygonal plate with Holes and Circular plate with Holes can be created and meshed with the given parametric values.

**M. Quadrilateral Plate**

The Quadrilateral prototype can be used to mesh a quadrilateral surface into small plate elements. Select the **Quadrilateral** prototype under the model type **Surfaces**. Drag the item into the right-side window and release the button. The **Select Meshing Parameters** dialog box will appear to specify the parameters.
Corners

Provide the relative coordinates of the corners of the Quadrilateral Surface or region you want to mesh.

Bias & Divisions

Specify the number of divisions you want along all the edges and the respective biasing. The minimum and maximum limits of number of divisions of each side are 1 and 100 respectively. Two opposite sides may have different numbers of divisions. When the number of divisions for two opposite sides are different, the sum of all divisions must be an even number for quadrilateral elements.

Bias

If you want equal divisions along the length of a side, keep the Bias as 1. If your intention is to divide a side in such a way that the length of the last division is five times the length of the first division, specify Bias for that side as 5 along with the number of divisions.

Biasing may be negative. When negative Biasing has been specified, the side is divided so that the first division length is the value of the Biasing times the last division length.

Element Type

Select the appropriate radio button depending on whether you want to mesh the region in smaller Triangular Elements or Quadrilateral Elements.

M. Cylindrical Surface

Select the Cylindrical Surface prototype under the model type Surfaces. Drag the item into the right-side window and release the button. The Select Parameters dialog box will appear to specify the parameters as shown in the next figure.
The Cylindrical Surface can be generated by providing the basic geometrical parameters **Length**, **Start Radius**, **End Radius** and **Sweep Angle**. You can generate a tapered cylinder by providing unequal values at **Start** and **End radius**. Entering a **Sweep Angle** less than 360 degree can also generate a longitudinally cut cylinder.

The **Axis** of the cylinder can also be controlled by entering the values of **Start** - X, Y, Z values and **End** - X, Y, Z values. The direction of the line joining the points gives the axis of the cylinder.

Providing the number of **Divisions along Length** and **Divisions along periphery**, the mesh can be generated. The option, **Generate open cylinder** will keep the ends open and **Generate triangular element** will generate triangles instead of quadrilaterals.

**M. Hyperbolic Paraboloid Shell**

Select the **Hyperbolic Paraboloid Shell** prototype under the model type **Surfaces**. Drag the item into the right-side window and release the button. The **Select Meshing Parameters** dialog box will appear to specify the parameters.

The basic geometrical parameters for generating a Hyperbolic Paraboloid Surface are the length of the two adjacent sides and the **Corner Dips**. The meshing parameters are the divisions along the adjacent edges. Click **Apply** after specifying all the parameters to generate the model.

![Select Meshing Parameters](image)

**M. Spherical Surface**

A Spherical Surface can be generated and meshed with this feature. Three types of Spherical Surfaces may be generated, viz., **Spherical Cap**, **Spherical Surface** and **Spherical Region**. The **Diameter of Sphere** is required for all those cases. **Base Diameter** is required for Cap and Region only. **Top Diameter** is required for Spherical Region only. For Spherical Surface you have to define the **Start Angle** and **End Angle** in degrees for both the directions - **Latitude** and **Longitude**.

For the purpose of mesh generation, the number of **Divisions** in both the directions is to be specified. Click **Apply** after specifying all these parameters to generate the model.

The **Select Meshing Parameters** dialog box is shown below in the case of a Spherical Surface.
**M. Polygonal Plate with Holes**

Select the **Polygonal Plate with Hole** prototype under the model type **Surfaces/Plates**. Drag the item into the right-side window and release the button. The **Define Meshing Region** dialog box will appear as shown below.

The Polygonal prototype allows us to mesh a polygonal surface, with or without different kinds of holes inside the boundary, into small triangular plate elements.

**Boundary**

The Boundary tab as shown above in the **Define Mesh Region** dialog box provides us an option to specify the **location of Corners, Number of Divisions** of each side and Bias of each side's division for the Boundary to mesh the surface.

X, Y, Z are the coordinates of the various corners of the surfaces. The sides will be defined as joining the various corners. **Div.** option is to define the divisions of various sides of the polygonal surface to be considered for generating the surface meshing. The **Bias** option helps the user to create divisions having unequal spacings among them.
On the top of the right side of this dialog box there are two icons namely, **Add New Row** and **Delete Row**. Clicking on the first icon will add a new row enabling us to specify the coordinates of the corner of the polygonal surface. Clicking on the second icon will enable us to delete an existing row.

**Holes**

After creating the boundary, the user can start introducing the holes in the plate. In STAAD, we may create circular, elliptical as well as polygonal holes.

When we click on the **HOLEs** option, two icons appear as shown below namely, **Add New Hole** and **Delete All Holes**.

- **Add New Hole**
  - This icon allows us to add new holes to the surface.

- **Delete All Holes**
  - This icon allows us to remove all the existing holes from the surface.

  Once a new hole is added, the name of the that hole appears under **HOLEs** in a tree view. A new icon titled **Rename Hole** will now appear which will enable us to rename the newly created hole.

**Hole**

To create a hole within the boundary, click this option. This is the default name of the hole. When we click on Hole, a table will be displayed on the right side of the dialog box, where we can define the geometry of the hole. Specify what kind of hole we want to create from among the three available options namely Polygon, Circle and Ellipse, in the **Region Type**, as shown in the next figure. For each hole, one tab will be created automatically in the **Define Meshing Region** dialog box to allow us to specify different parameters for that hole.

The creation and editing of the region types are explained below.

**Polygon**

This option is used to define polygonal holes. The geometry of the polygonal holes is generated in the same way as the geometry of the polygonal. Please refer to the description under polygonal surfaces for details on defining the geometry of polygonal holes.
Circle  This option is used to define circular holes. The parameters for defining the geometry of circular holes are described below:

Origin  We have to specify the X, Y, and Z coordinates in its proper places to define the position of the center of the circular hole.

Radius of circle  The value in this box will define the radius of the circular hole.

Division Along Periphery  The value in this box defines the number of divisions to be done along the circumference of the circular hole. This information will be considered in mesh generation of the surface.

Ellipse  This option is used to generate ellipsoidal holes. The parameters to define the geometry of ellipsoidal holes are as follows:
Origin
We have to specify the X, Y, and Z coordinates in its proper places to define the position of the center of the ellipsoidal holes.

Major Axis Radius, Minor Axis Radius
The values in these boxes will define the major axis and the minor axis of the ellipsoidal holes.

Division of each Quadrant
The values specified in this box specifies the number of divisions of each quadrant. This information will be used for the mesh generation of the surface.

Once all the parameters have been specified, clicking on OK to carry out the mesh generation operation of the surface. Clicking on Cancel will cancel the mesh generation operation. Clicking on Reset will reset the parameters provided at the beginning.

Note: The one limitation of the Polygonal Surface Meshing is that the total number of nodes must not exceed 15000.

M. Circular Plate with Hole
Circular Plate with hole is a special case of Polygonal Plate with Hole, where the Boundary is circular, keeping the other parameters unaltered.

Select the Circular Plate with Holes prototype under the model type Surfaces/Plates. Drag the item into the right-side window and release the button. The Define Meshing Region dialog box will appear as shown in the next figure.

The basic parameters required to define the circular plate geometrically are the location of the center (Origin) and Radius. To specify the plane of the circular plate the Normal Vector can also be defined. As the meshing parameter, Number of Division along Periphery is required.
M. Cooling Tower

A hyperbolic paraboloid shaped Cooling Tower may be generated and meshed with the parameters displayed in the Select Meshing Parameters dialog box as shown in the next figure.

The basic geometrical parameters required to model such a structure are Top Diameter, Throat Diameter, Height of Tower and Distance of Top from Throat. The Base Diameter is internally calculated and displayed to the user. For the purpose of mesh generation, the number of Division along Circumference and Division along Height is to be specified.

A complete model of a Cooling Tower is shown below.
M. Solid

A Solid rectangular block can be generated and meshed with the parameters displayed in the Select Meshing Parameters dialog box as shown below.

The required parameters are the Lengths along X, Y and Z directions and the corresponding Number of Divisions along those edges.

A Solid rectangular block is shown below.
M. Composite Model: Bunker or Silo

A Bunker or Silo can be modeled parametrically and meshed with this feature.

Select the Bunker or Silo prototype under the model type Composite Models. Drag the item into the right-side window and release the button. The Select Meshing Parameters dialog box will appear as shown below.
To define the geometry of the Vertical Portion, you have to define the **Length**, **Width** and **Height** of that portion along-with the number of **Divisions** along them for the purpose of mesh generation.

The **Depth of the Hopper Bottom** is required with the number of Divisions along depth. The **Length** and **Width** of the opening at the bottom is required and to locate this opening the **shift of Centroid** of the opening w.r.t. the axis of symmetry of the Silo is required.

Checking the box **Enable Edge Beam Generation** can generate edge beams and also checking the box **Enable Corner Column Generation** can generate Corner Columns, for which the **Height of Column from Top** is to be provided.

### M. Import CAD Model

This feature, Import CAD Model, has two separate utilities, Scan DXF and STAAD Models.

#### M. To generate geometry from a DXF file

This is a utility which allows the geometry (nodes, members, plates, etc.) of a previously created model to be imported and altered.

This feature supports a limited number of CAD entities like Line, 3D-Polyline, and 3D-Face.

If the geometry of a model is created using a drawing program like AutoCAD and saved in a DXF file, it can be imported into STAAD using this utility.

1. **Select Import CAD Models** from the **Model Type** drop-down list.
2. **Either:**

   Drag-and-drop the **Scan DXF** icon into the view window.

   or
Double-click the **Scan DXF** icon.
The **Open** dialog opens.

3. Select the DXF file you want to use and click **Open**.
The drawing geometry is opened in Structure Wizard.

### M. To generate geometry from a STAAD model

This feature can be used to import an existing model which can then be quickly scaled up or down in the Structure Wizard.

1. Select **Import CAD Models** from the **Model Type** drop-down list.
2. Either:
   - Drag-and-drop the **STAAD Model** icon into the view window.
   - or
   - Double-click the **STAAD Model** icon.
The **Open** dialog opens.
3. Select the STAAD input file (`.std`) you want to use and click **Open**.
The model geometry is opened in Structure Wizard.

### M. VBA Macro Models

This feature allows you to parametrically define models using a VBA Macro.

Two sample files are supplied with the program.

**Tip:** Select **File > Set as Top Most** to turn off that feature before launching a macro. Otherwise, the macro form may be hidden beneath the **Structure Wizard** application window.

- Dragging a macro icon from the left side of the window to the right to launch the macro.
- Double-click an icon on the left-hand side to open the code in the VBA editor. You can then make changes and save the file to suit your needs.

**Related Links**
- *EX. Macro Example Files* (on page 4310)

### M. To add a new plugin

1. Either:
   - Select **File > Add Plugin**
   - or
   - Right-click in the model types list and select **Add Plugin** from the pop-up menu.
The **Select an existing Macro** dialog opens.
2. Select the Visual Basic Macro file (file extension `.vbs`) you want to add and click **Open**.
The new macro is added to the list of plugins in the model types list.
M. To edit model parameters

1. Either:
   - Right-click in the view window and select **Change Property** from the pop-up menu.
   - or
   - Select **Edit > Change Property**.
   - or
   - Double-click on the model view window.
   - The **Select Parameters** dialog opens.

2. Change one or more parameters as needed.

3. Click **Apply**.

M. To rescale a model

1. Either:
   - Right-click in the view window and select **Scale** from the pop-up menu.
   - or
   - Select **Edit > Scale**.
   - The **Rescale Model** dialog opens.

2. Type in corresponding Z, Y, and Z scale factors in the fields.

3. Click **OK**.

M. To delete an entire model

Right-click in the view window and select **Delete** from the pop-up menu

M. To transfer the generated model to STAAD.Pro

1. Select **File > Merge Model with STAAD.Pro Model**.
   - A dialog prompts you to confirm you want to merge this prototype with your current STAAD.Pro model.

2. Click **Yes**.
   - The **Paste Prototype Model** dialog opens.
3. (Optional) Specify the method of offset:

**Tip:** This is useful, for example, to place a prototype truss model at the top of already modeled columns.

<table>
<thead>
<tr>
<th>Move option</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>By distance between following two nodes</strong></td>
<td>Type the node numbers</td>
</tr>
<tr>
<td><strong>By the following X, Y and Z values</strong></td>
<td>Type the coordinates (in the indicated units) where to place the prototype origin in the global coordinates of the STAAD model.</td>
</tr>
</tbody>
</table>

4. Click **OK**. The model is placed.

In the event that nodes, members, or elements overlap existing similar objects in the STAAD model, a message dialog opens indicating that the duplicate objects have been ignored. Click **OK** to proceed.

**M. To add items to the library**

You can customize the list of model types using the following procedure.

1. Select the **Model Type** from the drop-down list.
2. Either:
   - Select **File > Add Plugin**
   - or
   - right-click in the model type list and select **Add Plugin** from the pop-up menu
   - The **Open** dialog opens.
3. Select the library file (file extension .dll) for the plugin and click **Open**.
4. (Optional) To rename a selected model generator, do the following:
   a. Select a model generator and either:
      - Select **Edit > Rename Model Generator**
or

right-click on the model generator and select **Rename Model Generator** from the pop-up menu

The **Select Name** dialog opens.

b. Type a new name.

c. Click **OK**.

5. (Optional) Save the library of prototypes to a new file:

a. Select **File > Save As**.

The **Save As** dialog opens.

b. Type a new file name for the StWizard Model Files (file extension .stp) and click **Save**.

c. You can now open this file again by selecting **File > Open**.

---

**M. Pages in the Analytical Modeling Workflow**

- **Geometry** – used to layout your structure, including nodes, beams, plates, and solids

  **Note:** If you are using the Physical Modeling workflow, the majority of the tools on this page will be disabled. Model geometry for physical models must be updated in the STAAD.Pro Physical Modeler interface.

- Properties
- Specifications
- Supports
- Loading
- Analysis
- Design

---

**Nodes table**

Used to display a table of nodes with coordinates for adding and editing nodes. The table may also be used to highlight the node on the graphical view of the structure.

The **Nodes** table lists the node numbers and their coordinates. This table can be used to define new nodes and edit existing node-coordinates. If we click on a node number in this table, the node gets highlighted in the table as well as in the structure view.

Opens when the **Geometry** page is selected in the **Analytical Modeling** workflow.

- **Node** Lists the node numbers in numerical order.

  - **X** The X coordinates of the nodes in the currently selected unit. Changing this immediately changes the X-coordinate of the node in the graphical display also.

  - **Y** The Y coordinates of the nodes in the currently selected unit. Changing this immediately changes the Y-coordinate of the node in the graphical display also.

  - **Z** The Z coordinates of the nodes in the currently selected unit. Changing this immediately changes the Z-coordinate of the node in the graphical display also.

---

**Goto <object> dialog**

Used to go to a specific node within the **Nodes, Beams**, etc. table.

Opens when **Go To** is selected from the right-click pop-up menu on many tables.
Type the number of a node, beam, etc. and then click **OK**. The table will highlight that entry.

**Node Supports**
Lists all nodes for which supports have been defined along with the type of support.

---

### M. Properties and Specifications

#### M. Section Profiles

Beam members must have a section profile assigned for analysis.

STAAD.Pro supports a wide variety of section profiles, including catalog sections, prismatic sections, tapered member sections, and so on.

**M. To add a new table section property**

To add a table section property from a standard catalogs for steel, cold-formed steel, timber, or aluminum, use the following procedure.

These are also referred to as the “built-in” tables of sections in STAAD.Pro.

1. **Either:**
   - select the Properties page and then click **Section Database** on the Properties - Whole Structure dialog
   - or
   - select the Database tool in the Specifications group on the Specifications ribbon tab

   The **Section Profile Tables** dialog opens.

2. Select the appropriate table:
   a. Select the material tab at the top of the dialog:
      - **Steel**
      - **Coldformed Steel**
      - **Timber**
      - **Aluminium**
   b. Select the country catalog and shape profile on the left-hand side of the dialog.

   **Tip:** If you selected the material and country using the Database tool drop-down, then only that material and country tables are shown in the dialog.

3. Select the shape profile on the left-hand side of the dialog.
4. **Either:**
select the specific shape (i.e., beam, profile, shape, section, etc.) in the list

or

select to define a shape for some (i.e., pipes)

**Note:** Refer to related codes in the Design section (on page 944) for information on section nomenclature.

5. Select the appropriate **Type Specification** for some shapes.

Some type specifications require additional input (such as cover plate dimensions, spacing, composite slab data, etc.).

6. **(Optional)** Select an associated **Material**.

This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.

7. Either:

   **To...**

   add the section to the model for later assignment  

   add the section to the model and assign to the current member selection

   **Do the following...**

   click Add.

   click Assign.

8. **(Optional)** Repeat steps 2 through 7 as needed to add more sections to the model.

9. Click **Close**.

The section and, if selected, associated material, is added to the **Properties - Whole Structure** dialog.

If you did not assign the section to a selection set, you must select the section label in the **Properties - Whole Structure** dialog and assign it using one of the assignment methods.

- **Section Profile Tables dialog** (on page 2969)
- **TR.20.1 Assigning Properties from Steel Tables** (on page 2461)

**M. To add an American steel joist section**

To add an American steel joist section and, optionally, have it sized by span and load, use the following procedure.

STAAD.Pro includes the facilities for specifying steel joists and joist girders. The basis for this implementation is the information contained in the 1994 publication of the American Steel Joist Institute called "Fortieth edition standard specifications, load tables and weight tables for steel joist and joist girders." Member properties can be assigned by specifying a joist designation contained in tables supplied with the program, including the following joists and joist girder types:

- Open web steel joists – K series and KCS joists
- Longspan steel joists – LH series
- Deep Longspan steel joists – DLH series
- Joist Girders – G series

**Tip:** It is recommend that use the default selection of **Steel** material definition with joists.
1. Either:
   select the Properties page and then click Section Database on the Properties - Whole Structure dialog
or
   select the Database tool in the Specifications group on the Specifications ribbon tab

The Section Profile Tables dialog opens.

2. Select the Steel tab and then the American Steel Joist entry on the left-hand side.

3. Select the series of joists you want to use.

4. (Optional) To have the program select a least-weight option of joist for you, do the following:
   a. Type the search criteria (differs by joist series) in the Find suitable joist section fields.
   b. Click Find Section.
   For example, if you select the LH series of joists and then specify a Clear Span of 35 ft, a Depth Limit of 24 in
      (2ft), a Total Load of 750 lbs/ft (0.75k/ft), a Live Load of 500 lbs/ft (0.5k/ft), and a Deflection Limit of L/360,
      the program will select a 24LH09 when you click Find Section. The least weight suitable joist in the joist series
      will be selected. If not suitable joist can be found in the series, a message dialog opens.

5. Either:
   To... Do the following...
   add the section to the model for later assignment click Add.
   add the section to the model and assign to the current member selection click Asign.

6. Click Close.

Example Input

- *Section Profile Tables dialog* (on page 2969)

### M. To assign a prismatic section

To define and assign a prismatic section, use the following procedure.

1. **Either:**
   - select the **Properties** page and then click **Section Database** on the **Properties - Whole Structure** dialog
   - or
   - select the **Database** tool in the **Specifications** group on the **Specifications** ribbon tab

   The **Section Profile Tables** dialog opens.

2. **Either:**
   - select the Properties page and then click **Define** on the **Properties - Whole Structure** dialog
   - or
   - on the **Specifications** ribbon tab, select the **Prismatic** tool in the **Beam Profiles** group

   The **Property** dialog opens.

3. **Select the tab corresponding to the profile shape you want to use.**

   **Notes:**
   - The geometric shapes circle, rectangle, tee, trapezoidal, and general are typically used for concrete members.
   - Tapered I and tapered tube are typically used for steel members.
   - The Assign Profile tab is used to assign a profile shape for steel design for later member selection.

4. **Type the profile dimensions for the selected shape.**

5. **(Optional) Select an associated **Material**.**
   - This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.

6. **Either:**
To... Do the following...
add the section to the model for later assignment click Add.
add the section to the model and assign to the current member selection click Assign.

7. Click Close.

Related Links

• Property dialog (on page 2970)
• TR.20.2 Prismatic Property Specification (on page 2465)
• TR.20.2.1 Prismatic Tapered Tube Property Specification (on page 2467)

M. To assign a tapered I section

To define and assign a web-tapered I section, use the following procedure.

Note: $f_1$ (Depth of section at start node) should always be greater than $f_3$ (Depth of section at end node). You must provide the member incidences accordingly.

Tapered I-sections have constant flange dimensions and a linearly varying web depth along the length of the member.

Shear deformation is not considered for tapered I-Beams and tapered poles. This means that the SET SHEAR command has no effect on the deformation computed for members with these cross sections.

The Tapered I dialog opens.

2. Select an associated Material.

This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.

Note: Tapered I sections are typically steel or aluminum members.

3. Specify the profile dimensions for the shape.
4. Either:
   
   **To...**
   
   add the section to the model for later assignment
   
   add the section to the model and assign to the current member selection
   
   **Do the following...**
   
   click Add.
   
   click Asign.

5. Repeat steps 2 through 4 as needed to add more tapered I sections to the model.

6. Click Close.

The section and, if selected, associated material, is added to the Properties - Whole Structure dialog.

If you did not assign the section to a selection set, you must select the section label in the Properties - Whole Structure dialog and assign it using one of the assignment methods.

**M. To create a general section**

To create a user provided table section with a general profile, use the following steps.

You may want to change the input dimensions prior to creating user provided table sections. Select **Tools > Set Current Input Unit** to do so.

1. On the Specification ribbon tab, select the User Table > User Table Manager tool in the Beam Profiles group.

   ![User Table Manager]

   If no User Defined Table exists, you will be prompted to create one.

   The User Table Manager dialog opens.
2. Click New Table.
   The New User Table dialog opens.

3. In the Select Section Type list, select GENERAL and then click OK.
   The dialog closes and the Select Existing Table list in the User Table Manager dialog now has at least one entry.

4. Click Add.
   The General dialog opens.
5. Type a **Section Name**.

6. Either:

   Type the section properties if these are available in the corresponding fields
   or

   Set the **Define Profile Polygon** and enter in Z,Y coordinates of the section apexes.

   **Tip:** These values may be copied and pasted from a spreadsheet.

   The following is an example cross section, with corresponding Z,Y coordinates which can be copy/pasted directly into the table.

<td>0</td>
</tr>
</tbody>
</table>

7. (Optional) If you entered in section corner coordinates, click **Compute Section Properties**

The section properties are calculated and the fields are updated. The coordinates are also updated from an arbitrary origin to the an origin at the center of gravity of the cross section.
Tip: You can manually overwrite any of these values if necessary.

8. (Optional) If you want to have section stress calculated, enter Y,Z coordinates in the **Stress locations in local coordinates**

Tip: The coordinate locations for stresses should be based on the center of gravity of the section, rather than an arbitrary data point. These may be copied/pasted from the re-centered apex coordinates table.

9. Click **OK**.

The section is added to the list in the **Create User Property Table** dialog.

10. (Optional) Repeat steps 4 through 9 to add more General sections.

11. Click **Close**.

The section can now be added for use in the **Properties - Whole Structure** dialog (on page 2968) by selecting it in the **User Property Table** dialog.

**Example**

The example given in 6 above creates the following lines in a STAAD input file:

```plaintext
... TABLE 1 UNIT INCHES KIP GENERAL General1 152 16 0 20 0 3395.93 4520.67 638.828 332.591 452.067 83.3308 - 46.3944 760 625.529 95637.5 16 PROFILE_POINTS -10 5.78947 -10 1.78947 -6.5 1.78947 -6.5 -10.2105 -3.5 -10.2105 -3.5 1.78947 3.5 1.78947 -3.5 -10.2105 6.5 -10.2105 6.5 1.78947 10 1.78947 10 5.78947 STRESS_LOCATIONS -10 5.78947 10 5.78947 -6.5 -10.2105 6.5 -10.2105 END ...```

**Related Links**

- G.6.3 User-Provided Steel Table (on page 2325)
- TR.19 User Steel Table Specification (on page 2446)
- TR.20.4 Property Specification from User Provided Table (on page 2469)
- Create User Provided Table dialog (on page 2974)
- User Provided Table dialog (on page 2973)

**To use a general shape created in Section Wizard**

To use a general shape created in Section Wizard as a user provided shape table in STAAD.Pro, do the following.

You must create a profile outline in Section Wizard and export it as a General Shape (file extension .upt) for use in STAAD.Pro. Refer to TR.20.10 Member Property Reduction Factors (on page 2485) for details.

**Note:** This profile shape should consist of only an outer contour. Any internal voids such as internal contours or openings will be ignored, though section properties calculated by Section Wizard based on sections with voids will be used.
1. On the **Specification** ribbon tab, select the **User Table > User Table Manager** tool in the **Beam Profiles** group.

   ![User Table Manager](image1)

   If no User Defined Table exists, you will be prompted to create one.

   The **User Table Manager** dialog opens.

2. Click **New Table**.

   The **New User Table** dialog opens.

   ![New User Table](image2)

3. Specify the new external table:
   a. In the **Select Section Type** list, select **GENERAL**.
   b. Check the **External Table** option.
   c. Click **Browse**.
   d. Navigate to and select the '.upt' file exported from Section Wizard and the click **OK**.

   The dialog closes and the **Table Data** in the **User Table Manager** dialog shows the name of the profile read from the '.upt' file.
4. (Optional) To view the calculated section properties, select the profile entry in the **User Table Manager** dialog and then click **View**. The **General** dialog opens.

5. Click **Close**.

The section can now be added for use in the **Properties - Whole Structure** dialog (on page 2968) by selecting it in the **User Property Table** dialog.

**Tip:** Changing the structure diagram to display 3D rendering types for Full Sections or Sections Outline will display the shape profile. Similarly, 3D renderings of the structure will also display the shape profile.
M. To assign catalog section to physical members

To select and assign a catalog section to physical members, use the following procedures.

**Note:** For a physical member whose physical member property is already assigned, the individual analytical members in that Physical member will adopt the same member property that of the physical member. However, in case, where the analytical member property is assigned to any member in that physical member, then this analytical member property will supersede physical member property.

1. Select the Properties page.
   The **Properties - Whole Structure** dialog opens.
2. On the **Geometry** ribbon tab, select the **Toggle Physical Member Mode** tool in the **Physical Members** group.
   
   The tool is highlighted to indicate the mode is active.
3. Either:
   select the **Properties** page and then click **Section Database** on the **Properties - Whole Structure** dialog
or

select the Database tool in the Specifications group on the Specifications ribbon tab

The Section Profile Tables dialog opens.

4. Select the appropriate table:
   a. Select the material tab at the top of the dialog:
      - Steel
      - Coldformed Steel
      - Timber
      - Aluminium
   b. Select the country catalog and shape profile on the left-hand side of the dialog.

   **Tip:** If you selected the material and country using the Database tool drop-down, then only that material and country tables are shown in the dialog.

5. Select the shape profile on the left-hand side of the dialog.

6. Either:
   - select the specific shape (i.e., beam, profile, shape, section, etc.) in the list
   - or
   - select to define a shape for some (i.e., pipes)

   **Note:** Refer to related codes in the Design section (on page 944) for information on section nomenclature.

7. Select the appropriate Type Specification for some shapes.
   - Some type specifications require additional input (such as cover plate dimensions, spacing, composite slab data, etc.).

8. (Optional) Select an associated Material.
   - This feature allows you to use material definitions for steel, stainless steel, concrete, aluminum, or any previously specified, custom material definitions.

9. Click Add.
   - The new member property is added to the list as a Physical member property in the Properties - Whole Structure dialog. Such properties are designated with the word “Physical”.

   **Note:** Only the Physical Member properties can be assigned to a physical member, and no analytical member property can be assigned to a physical member.

10. Click Close.
    - You must assign the physical member properties to physical members using one of the standard assignment methods from the Properties - Whole Structure dialog.

   **Related Links**
   - *M. Physical Members* (on page 649)

   **M. Section Wizard Help**
M. To start Section Wizard

Section Wizard consists a set of utility programs used to generate custom sections for use in STAAD.Pro.

1. Open a model in the STAAD.Pro Analytical Modeling workflow.
2. On the Specifications ribbon tab, select Section Wizard tool in the Tools group.

The Section Wizard program opens.

Alternatively, you can locate the file \SectionWizard\Section.exe in the folder where STAAD.Pro was installed on your computer.

M. Section Builder

The Section Builder module is used to calculate the properties of sections built up from an arrangement of cross sections taken from a number of standard tables. This module is composed of two windows. The main Section Builder window, which displays the composite section along with a number of tools to manipulate the sections and the Section Element dialog box which is used to select the sections to be used and method of locating them onto the current overall section.

M. Application Window Layout

The main Section Builder window displays the current composite section. All of the primary commands are activated through the menus along the top of the window. There is also a status bar along the bottom of the window which displays the overall dimensions of the composite section and the location of the cursor when it lies over the main workspace. Additionally a dimension value will be displayed in the status bar by clicking and dragging the mouse across the window.

Sections created in the Section Dialog box can be located onto a composite section relative to the nodes of the 'current section.' A section is made into the current section simply by clicking on it so that it is shown in yellow. Note how the nodes of the current section are identified as potential locating points for the addition of new sections.
Window controls

### M. Equivalent Section module

This module is used to find a best fit solution from the table of values of area, inertia, and elastic moduli. The data can either be entered directly into the table, or generated from the Section Builder or Free Sketch modules, or from the Standard Section toolbar command.

#### Section Types

The Equivalent Section module then finds the best fit on one of the following section types:

1. I Section, with independent dimensions for the top and bottom flanges
2. Rectangular Hollow Section, with separate dimensions for the side walls and the top and bottom flanges
3. I Section, with the same sizes for the top and bottom flanges
4. Rectangular Hollow Section, with the same thickness for the flanges and the side walls
5. Channel Section

Each of the values can be weighted for importance by setting a bias for that value. The larger the bias, the more the program will attempt to match that value rather than any of the others.

M. Application Window Layout

![Equivalent Section module window](image)

**Figure 110: Equivalent Section module window**

Window controls

**Toolbar**
A series of commonly used tools are arranged at the top of the module window.

**Properties table**
A list of the reference property values and bias values are entered here to provide data for the cross-section search. Once the Find button is clicked, a set of associate Replacement values and the percent Error will also be displayed, along with a graphical representation of the found equivalent section dimensions.

**Equivalent cross-section**
A group of controls are arranged here depicting general cross-section types. The currently selected type is shown as depressed.

**Find**
Click to perform a search for an equivalent cross-section based on the specified section Values, weighted per the specified Bias values.

**Round dimensions**
Select this option to have the search use rounded dimensional values. If a search has already been performed, then the current dimension results are rounded.

**Exit**
Closes the module. Any unsaved data will be lost.

**Help**
Opens the Section Wizard help window to display the relevant help topic.
**Views panels**  A graphical representation of a section as well as dimensions of the recommended section from a Find action are displayed in the right-hand side of the window.

**M. Toolbar**
A list of tools found in Equivalent Section.

<table>
<thead>

### Tool Description

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch Section Builder module</td>
<td>Launches the Section Builder module of Section Wizard and creates section based on the section that was 'found'</td>
<td></td>
</tr>
<tr>
<td>Launch Free Sketch module</td>
<td>Launches the <a href="#">c_Free_Sketch_module</a> of Section Wizard and creates section based on the section that was 'found'.</td>
<td></td>
</tr>
<tr>
<td>Export STAAD User Database</td>
<td>This allows the current section data to be used to create STAAD External User tables. There are two types of database that can be created, either a Prismatic Section or a General Section. Selecting either command will ask for a name of file to be used. If the filename chosen exists already, then the current section will be added to the bottom of the file.</td>
<td></td>
</tr>
</tbody>
</table>

**M. Preferences dialog**

Used to set preferences for the Equivalent Section module.

**Units Measures tab**
Select the units for angles, section dimensions, section properties, axial forces and moments, as well as the number of decimal places and whether or not to use an exponential form.

Misc. tab

Select the language, Report settings such as the template document, whether the documents should use Word 7 or Word 97 file formats, the paper size and font. Set whether documents should be sent direct to the printer or
into Word for editing. Additional options determine the number of vertices to created by a circle, option to snap to grid and whether the ends of vertices are indicated by a circle or not.

Profile Databases tab

Select the range of databases that are referred to by the program. See Appendix 2: Section Databases for a current list of available database sections.

Other Controls

These controls are displayed at the bottom of the dialog for all tabs.

- **Apply**: Saves any changes made in the dialog.
- **Cancel**: Closes the dialog without saving any changes.
- **Help**: Opens the Section Wizard help window to the relevant topic.

M. Section dialog
Dialog controls

**Section type selectors**

**Cover Plate dimensions** (For I-sections with cover plates only) These fields become active when the I-section with cover plate type is selected. Specify values for \( b_1 \) and \( h_1 \) (width and thickness of top cover plate, respectively) as well as \( b_2 \) and \( h_2 \) (width and thickness of bottom cover plate, respectively).

- **Database**
- **Family**
- **Section**
- **Cancel**
- **OK**

**M. Free Sketch**

Used to create sections with an outer boundary of any shape with a number of internal openings if required.

Free Sketch data files can be saved in either one of two formats. `<filename>.CNS` is a binary file format which is the most compact and preferred way to store files. Alternatively, files can be stored as `<filename>.CON`, stores the file in an ASCII format which can be opened and edited by any text editor, such as Windows Notepad.
**M. To set up the drawing environment**

The scope of the section is determined by first setting the overall dimensions of the workspace to extend to (at least) the maximum dimensions of the section that is to be considered. A grid is then placed within this workspace, which if selected in the options, can be snapped to in order to accurately locate the coordinates of the boundary nodes.

1. Select either:
   
   Edit > Overall dimensions
   
   or
   
   the Overall dimensions tool
   
   The Overall dimensions dialog opens

2. Type the maximum width and height of your section.

   **Tip:** This can be edited later by repeating this procedure.

3. Click OK.
   
   The section axis is displayed.

4. To set up a grid, do the following:
   
   a. Select either:
       
       Settings > Grid options
       
       or
       
       the Grid step tool
       
       The Grid parameters dialog opens.
   
   b. Type the Y and Z direction grid increments.
   
   c. (Optional) Type an Angle used to orient the grid.
   
      The angle is measured positive counter-clockwise from the Y axis.
   
   d. Click OK.

5. To display the grid, select either:
   
   Settings > Grid
   
   or
   
   the Grid tool
   
   The grid is displayed and the tool is depressed on the toolbar and in the menu.

6. To snap points to the grid, select Settings > Snap to grid.

   **Note:** This tool is on by default when the grid is displayed.

**M. To draw an external contour**

Used to define the outside of the section shape.

Only one closed shape may be used to define a cross section.
1. Select either
   \textit{Edit > Draw External Contour}
   
or
   the \textit{External Contour} tool

2. Click any point in the View window as the first vertex of the exterior of the shape.
   A line is rubber-banded between this point and the mouse pointer.

3. Click subsequent points to form additional vertices.

   \textbf{Tip:} You may right-click to undo a previous vertex.

4. Double click the final point once you have formed a closed geometric shape.
   The final point does not need to be a previously entered data point. The rubber band to the first point will give you a preview of what the shape will look like for any point in the View window.
   The shape is shaded solid.

5. Exit the external contour drawing mode by either
   - repeating step one
   - or
   - select some other drawing mode

\textit{M. To draw an internal contour}

Used to define the openings or negative spaces within the cross section shape.
Inner contours must be closed shapes. Inner contour areas or vertices may not overlap.

1. Select either
   \textit{Edit > Draw Internal Contour}
   
or
   the \textit{Internal Contour} tool

2. Click any point in the View window as the first vertex of the inner contour.
   A line is rubber-banded between this point and the mouse pointer.

3. Click subsequent points to form additional vertices.

   \textbf{Tip:} You may right-click to undo a previous vertex.

4. Double click the final point once you have formed a closed geometric shape.
   The final point does not need to be a previously entered data point. The rubber band to the first point will give you a preview of what the shape will look like for any point in the View window.
   The shading inside of the shape is removed.

5. Exit the internal contour drawing mode by either
   - repeating step one
   - or
   - select some other drawing mode
**M. To round a corner**

Uses this procedure to round –also referred to as fillet– interior or exterior contour corners.

1. Select either
   
   **Edit > Radius Corner...**
   
   or
   
   the **Smooth tool**
   
   2. Select any interior or exterior contour vertex.

   **Tip:** When hovering over a vertex, the mouse pointer changes to a double-line cross-hair (\(\phi\)).

   The Smooth Radius dialog opens.

   3. Type a radius value, \(R\), and click **OK**.
   
   The previously specified radius is the default value.

   The corner is redrawn as a series of points forming an arc with the specified radius.

   4. Exit the radius drawing mode by either
   
   repeating step one
   
   or
   
   selecting some other drawing mode

**M. To insert a round opening**

Use the following procedure to insert a round hole by one of two means.

A hole is an interior contour which is parametrically defined with a center and radius. You may specify a radius by an exact value or by drawing in the View window, depending on your tool selection.

1. Select either
   
   the **Circle hole tool**
   
   or
   
   the **Circle hole with specified radius tool**
   
   If you selected to specify a radius, the **Radius of the circle hole** dialog opens.

   2. If you selected to specify a radius, enter the value and click **OK** in the **Radius of the circle hole** dialog.

   3. Click a point to define the center of the circular hole.
   
   If you are defining the radius graphically, a circle is rubber-banded to the mouse pointer. Otherwise, the hole is drawn with the previously specified radius.

   4. Double click a point to define a radius.
   
   The hole is drawn.

   5. Exit the hole drawing mode by either
   
   repeating your selection in step one
   
   or
selecting some other drawing mode

**M. To copy an internal contour**

Use this procedure to make a copy of any internal contour or hole.

Inner contours must be previously specified for the tools used to be active.

Inner contours can be placed anywhere within the external contour.

1. Select either

   - **Edit > Copy inner contour**
   
   or
   
   the **Copy inner contour(s)** tool

2. From there, select either to use a **Rectangle** or **Polygon** window method for performing a selection.

   Depending on the window method selected, the mouse pointer either changes to a rectangular selection icon (rectangular) or a polygonal selection icon (polygon).

3. Click an initial point outside of the inner contour(s) you wish to copy.

   Depending on the window method selected, either a rectangle (rectangular) or a single line (polygon) is rubber banded to your mouse pointer.

4. Select the next point based on the following:

   For a rectangle, select the opposite corner of the rectangular window enclosing all of the inner contours you wish to copy.

   or

   For a polygon, click the next vertex along the polygon defining the outer edge of the window area. Repeat this step until the contours you wish to copy are enclosed, double-clicking the last point to close the polygon.

5. Specify a location of the copy by either

   Clicking anywhere within the windowed area and dragging the copy to where you wish to place it. Your mouse pointer becomes a multi-arrow icon to indicate this option.

   or

   Right-click to open the **Copy of contour(s)** dialog which is used to specify Y and Z offsets. Click **OK** to place the copy at this location.

Copies inner contours or their vertices may not overlap with other inner contours.

**M. To delete vertices**

Use this procedure to remove the vertices of external or internal contours.

1. Select either

   - **Edit > Delete vertices**
   
   or

   the **Delete vertices** tool
2. From there, select one of the following methods for vertex selection:
   Single
   or
   Rectangle
   or
   Polygon
   The mouse pointer updates to reflect the selection method.
3. Select either:
   a single vertex to delete; the mouse pointer changes to a double-line cross-hair (▲)
   or
   one corner of a rectangle window; the mouse pointer changes to a rectangular selection icon (□)
   or
   the first vertex of a polygon window; the mouse pointer changes to a polygonal selection icon (■)
   A single point selection is deleted and the shape is redrawn connecting the adjacent points. Once one or more vertices are enclosed in a completed rectangle or polygon window area, then those vertices are deleted and the adjacent vertices to those are connected.

M. To delete an opening

Use this procedure to delete an interior contour or hole from the shape.
Inner contours must be previously specified for the tools used to be active.

1. Select either
   Edit > Delete internal contour
   or
   the Delete tool
2. Click anywhere inside the contour or hole you want to remove.
   The internal contour is removed from the shape.
3. Exit the delete contour mode by either:
   repeating step one
   or
   selecting some other drawing mode

M. To shift the coordinate center

Use this procedure to shift the coordinate center to any arbitrary point or to the center of gravity.

1. Select Edit > Coordinate Center
   The Coordinate Center dialog opens.
2. Specify a new coordinate center by either
    specifying both Y and Z shift values and click Apply
    or
    click Shift to specify the current shape center of gravity.

    **Note:** The origin must remain within the overall dimensions of the workspace.

    The coordinate origin shifts to the specified location.

**M. To import a CAD drawing**

This procedure is used to import a 2D CAD, closed area as a section profile. This allows you to use the CAD program of your choice to generate complex cross sections.

The following AutoCAD® entity types are supported in the import facility:

- 3DFACE
- SOLID
- TRACE
- LINE
- POLYLINE
- LWPOLYLINE
- ELLIPSE
- CIRCLE
- ARC

1. Select **File > Import DXF**
   The Import dialog opens.
2. Navigate to and select the .dxf file which you want to import.

    **Note:** The files that are to be imported are such that all the vertices are in a single plane and form closed areas.

3. Click **Open**.

   **To export shape for use in STAAD.Pro**

To export the shape profile for use in STAAD.Pro as a user-provided table, do the following.

    **Note:** This profile shape should consist of only an outer contour. Any internal voids such as internal contours or openings will be ignored, though section properties calculated by Section Wizard based on sections with voids will be used.

1. Select **File > Export to STAAD.Pro > General Section.**
   A **Save As** dialog opens.
2. Navigate to where you want to save the file, type a file name, and then click **Save**.
   The **User Table Units** dialog opens.
3. Select the unit of length for use with this shape and then click **OK**.
   The **General** shape dialog opens.
4. Type the **Section Name** for use in the STAAD.Pro user provided table.
5. (Optional) Type in any override values for section properties you want to use instead of those calculated by Section Wizard.

The shape vertices and calculated section properties are saved to the .upt file.

You can use this file as an external file for a user-provided section. Refer to To use a general shape created in Section Wizard (on page 739).

**M. Application Window Layout**

**Drawing Window**

Left click selects a data point. Double click to accept. Right click to void last data point or current action (same as selecting the Cancel operation tool).

**M. Toolbar**

Contains several of the most commonly used tools found in the Free Sketch module.

M. Properties and Specifications
### Menu item | Description | Shortcut
---|---|---
Grid Options ... | Opens the Grid Parameters dialog, which is used to specify the grid spacing along the Y and Z directions and the Angle of rotation of the grid axes. |  
Grid | Used to set or clear the display of the drawing grid in the View window. |  
Snap to grid | Used to set or clear the snap to grid behavior, which provides drawing assistance by selecting the nearest grid point to a selected point in the View window. |  
Snap to vertices | Used to set or clear the snap to vertices behavior, which provides drawing assistance by selecting the nearest vertex point to selected in the View window. |  
Center of Gravity | Used to set or clear the icon that shows the location of the center of gravity. |  
Shear Center | Used to set or clear the icon that shows the location of the shear center. |  
Coordinate Axis | Used to set or clear the display of the coordinate axis. |  
Principle Axis | Used to set or clear the display of the principle axis of the current cross section. |  
Zoom In | Used to increase the magnification in the View window. |  
Zoom Out | Used to decrease the magnification in the View window. |  

M. Preferences dialog  
Used to set the units, colors, output types, and databases for standard sections. 
Opens when **Settings > Preferences ...** is selected.  
Units of measurement tab
Select the units for angles, section dimensions, section properties, axial forces and moments, as well as the number of decimal places and whether or not to use an exponential form.

Misc. tab

Select the language, Report settings such as the template document, whether the documents should use Word 7 or Word 97 file formats, the paper size and font. Set whether documents should be sent direct to the printer or into Word for editing. Additional options determine the number of vertices to created by a circle, option to snap to grid and whether the ends of vertices are indicated by a circle or not.

Stress scale tab

Used to set the colors of the maximum compression and tension stresses and the colour these grade to for zero stress, along with the number of bands to be displayed.

Profile databases tab

M. Grid Parameters dialog
Used to specify the grid spacing along the Y and Z directions and the Angle of rotation of the grid axes.

Opens when Settings > Grid Options ... is selected.

Dialog controls

Y       Grid spacing along the section local y axis (horizontal on screen).
Z       Grid spacing along the section local z axis (vertical on screen).
Angle   Angle from the coordinate axis to the grid lines, taken counterclockwise. Accepted values range between zero (inclusive) and 90 degrees. Negative values are not accepted. Only the drawing grid is rotated; no section data is changed.
OK      Saves changes and closes the dialog.
Cancel  Closes the dialog without saving any changes.

M. Service menu
Contains items for opening tools and utilities related to the Free Sketch module.

Table 40: Service menu items

<table>
<thead>
<tr>
<th>Menu item</th>

**M. Formula Calculation window**
Used for holding evaluations under the formulas, which are set by the user in the window of lead

![Formula calculation window](image)

*Figure 112: Formula calculation window*

**Formula Syntax**
At lead of the formulas it is necessary to observe the following rules:
- the names of functions are entered by lower case letters of the Latin alphabet;
- a separator of fractional and whole parts of number is the point;
- the arithmetical operations are set by characters +, -, *, /, exponentiation ^ (for example, 2.5*2.5*2.5 is typed as 2.5 ^ 3).

**Supported Functions**
At record of the formulas it is possible to use the following functions:
floor - the greatest integer not exceeding preset
tan - a tangent
sin - sine
cos - cosine
asin - an arcsine
acos - an arccosine
atan - an arctangent
exp - an exponential curve
ceil - the least integer exceeding preset
tanh - a tangent hyperbolic
sinh - sine hyperbolic
cosh - cosine hyperbolic
log - a Napierian logarithm
log10 - a Brigg's logarithm
abs - an absolute value
sqrt - the radical square

Depending on a state of the switch Degrees / radians, arguments trigonometrically functions (sin, cos, tan) and
the outcomes return trigonometrically functions (asin, acos, atan) are reduced in degrees or radians accordingly.

Usage only of parentheses is admitted at arbitrary depth of an enclosure.

**Examples**

The formula:

\[ 1.2 + \sin (0.43) + 6.7\sqrt{6.8 - \sqrt{\sqrt{0.003}}} \]

is typed as follows:

\[ 1.2 + \sin (0.43) + 6.7\sqrt{6.8 - \sqrt{\sqrt{0.003}}} \]

Click Variable and then the \(x\), \(y\), and \(z\) fields become active. Thus values of variables are set in
appropriate windows of lead. It allows to carry out a series of one-type evaluations at different values
of parameters. For example, in this condition the following formula

\[ 1.2 + \sin (x) + 6.7\sqrt{6.8 - \sqrt{y}} \]

is typed as follows:

\[ 1.2 + \sin (x) + 6.7\sqrt{6.8 - \sqrt{y}} \]

Then click Calculate to have the program resolve the variables into the formula.

Click Copy to copy the result to the Windows clipboard.

Moreover, the program allows to input some symbolic expression (depending on the variables \(x,y,z\));

\[ \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \text{ or } \frac{\partial f}{\partial z} \]

and retrieve symbolic expression for the corresponding partial derivative.

**M. Unit Converter**

This is a utility program used to convert measurements from a known units of measurement into several
different units.
The dialog includes several tabs, each corresponding to a type of measurement.

- Length
- Area
- Volume
- Force
- Angle
- Pressure
- Moment of Couple

To convert units

1. Select the tab with the type of measurement you want to convert.
2. Type the known value in the field with the known units.
3. Press <Enter>. The value is converted in each field with different units on this tab.

Tip: You can double-click in a field to quickly select the contents. Right-click and then select Copy from the pop-up menu to save this value to the Windows clipboard.

Click Exit when you are finished converting values.

M. Section Database Manager

This utility application is used to manage the section catalog databases used in STAAD.Pro.

M. To change a default section database

To change the section database used the default for a particular country and material combination, use the following procedure.

1. Select the Section Database tool in the Tools group on the Specifications ribbon tab.

The Section Database Manager application opens.

2. On the Home ribbon tab, select the Configuration tool in the Options group.

The Default Database Configuration dialog opens.

3. (Optional) Select the Default Country from the drop-down list.
   This will be the first country expanded when the Section Profiles Tables dialog open is opened.

4. Select the tab corresponding to the material type.

5. For a particular Country, select a default database from the drop-down list in the Selected Database field.

6. Repeat steps 4 and 5 to change additional default databases.

7. Click Save.

8. Click Close.
Alternatively, you can navigate to the database you want to use as the default for a particular country and material combination in the Contents panel. Then, right-click and select Set as Default Database from the pop-up menu.

M. To add a custom table section property

To edit the section database tables to include custom sections, use the following procedure.

Note: This is not the same as adding a user-defined section or catalog. This should only be performed if you need to make edits to the standard shape catalogs that are included with STAAD.Pro.

1. Select the Section Database tool in the Tools group on the Specifications ribbon tab.

The Section Database Manager application opens.

2. In the Databases list, double-click on the country, material, catalog, and table you want to edit.

   The selected table opens in read-only mode.

3. Select the Lock tool.

   The table is unlocked for editing.

4. Either:

   To... Do the following...

   add a row to the end of the table select the Append Row tool

   add a row above the current table row select the Add Above tool

   add a row below the current table row select the Add Below tool

   The order of the table here is how it will also be presented in the Section Profile Tables dialog in STAAD.Pro.

   An empty row is added to the table.

5. Type a record number (RECNO), name, STAAD.Pro nomenclature name (StaadName), and then the section values for each column in the table.

   You can press <Tab> to move to the next column within a row when entering values.

6. (Optional) Repeat steps 4 and 5 as many times as needed to add additional shapes.

7. Click Commit to save the changes to the database.

8. Select the Unlock tool.

   The database is now locked against further editing.

9. Close the SectionDBManager program.

You can now use this section just as you would any default catalog section in STAAD.Pro.

Note: You can use the Delete Row tool to remove the current selected table row. Exercise caution when using this tool!
**Default Database Configuration** dialog

Used to select the default country and section databases to use in the **Section Profiles Table** dialog.

Opens when the **Configuration** tool is selected on the **Home** tab in the **Section Database Manager** application.

When an existing STAAD.Pro model is opened, the program reads the contents of the file, and checks the validity of data in that file. One of those data items validated is names of sections assigned from steel tables. Since steel sections are country-specific, such as British, German, etc., the program needs to know the country or organization whose steel table is the underlying database for validating the sections being read in from the file. Normally, the input file contains the name of the database as part of the member property command. In the absence of an explicit name, STAAD.Pro uses a default. That default is set using this facility.

**Section Profile Table tab**

**Default Country**

Select the default country to display when the **Section Profiles Table** dialog opens.

**Tables Selection**

The materials are organized as tabs along the top of the table. For each material, the countries are listed along with the default catalog to use for each. Select the catalog from the drop-down list for each as needed.

**Custom Profile Table**

Used to associate a user-defined section table with STAAD.Pro.

STAAD.Pro profile table files are Microsoft Office Access® database files (file extension .mdb).

**Category**

Select the profile category (typically material and/or country) with which the profile database is to be associated.

**Table**

Type the name of the STAAD.Pro profile table file (file extension .mdb) to add or click [...] to browse for a file.

**Add**

Adds the selected custom profile table to the program.

### M. Materials and Constants

You can use material definitions or assign individual material constant values to beams, plates, and solids.

**Note:** Material definitions are recommended for most models.

### M. To create a material definition

To create a new isotropic material definition for use with your model, use the following procedure.

You may want to set the input units to a familiar set of units for defining materials before creating a new material definition.

STAAD.Pro includes a set of predefined materials for concrete, aluminum, steel, and stainless steel.

2. In the Material - Whole Structure dialog Isotropic tab, click Create.

   The Isotropic Material dialog opens.
3. Type a **Title** to identify the material.
   This title must be different than the predefined material names or any other existing user-defined material name.

4. Type the values of the Material Properties used for analysis:
   
   - Young’s Modulus, $E$
   - Poisson’s Ratio, $\nu$
   - Density, $\gamma$
   - Thermal Coefficient, $\alpha$
   - Critical Damping
   - Shear Modulus, $G$

5. Select the **Type of Material** from the drop-down list.

6. Type the strength values in the **Design Properties** section.
   
   The fields corresponding to the selected material type are active.

7. Click **OK**.

The material definition is now added to the **Materials** table and is available for selecting when assigning shapes and in **Material - Whole Structure** dialog.

**Related Links**

- *TR.26.1 Define Material* (on page 2501)
M. To create an orthotropic material

To create a 2D orthotropic material definition for use with orthotropic plate elements, use the following procedure.

You may want to set the input units to a familiar set of units for defining materials before creating a new material definition.

**Note:** 2D orthotropic material definitions are for use with plate elements only.

1. Select the **Materials** page in the **Analytical Modeling** page control bar.

   The **Material - Whole Structure** dialog and the **Materials** table open.

2. In the **Material - Whole Structure** dialog, select the **Orthotropic 2D** tab.

3. Click **Create**.
The 2-D Orthotropic Material Property dialog opens.

4. Type a Title for the material.
5. Type the material values:
   a. Type the Young's Modulus and Thermal Coefficients in the X direction.
   b. Type the Young's Modulus and Thermal Coefficients in the Y direction.
   c. Type the Density, Critical Damping, and Poisson's Ratio values.
      The same values are used in both X and Y directions.
   d. Type the Shear Modulus values for in-plane shear ($G_{xy}$), shear transverse to the local Y-Z direction ($G_{yz}$), and shear transverse to the local Z-X direction ($G_{zx}$).
6. Click Add.

The material definition is now added to the Materials table and is available for selecting when assigning shapes and in Material - Whole Structure dialog.

Related Links
- TR.26.1 Define Material (on page 2501)
- 2D Orthotropic Material Property dialog (on page 2989)

M. To assign material definitions

To assign material definitions to model objects (beams, plates, or solids), use the following procedure.

Often, you will assign a material definition to a beam along with the section assignment or to a plate with the thickness definition, as the material and profile or thickness are typically intrinsically associated. However, if you need to change materials or make assignments separately, this is done using the Material - Whole Structures dialog.

2. Select the Materials page on the Analytical Modeling workflow page control bar.

3. Assign the materials using one of the standard assign methods in the Material - Whole Structures dialog.

M. To assign material constants

To assign material constants to model objects (beams, plates, or solids), use the following procedure.

You may want to set the input units to a familiar set of units for a particular material value before assigning a material constant.

Tip: It is recommended to use material definitions in place of material constants. Material definitions also allow you to assign design strength properties.

1. Select the model object which have the same material constant.
2. On the Specifications ribbon tab, select the Constants tool in the Materials group.

A drop-down list of material constants opens.

3. Select the constant you want to assign:

   - Young's Modulus
   - Poisson's Ratio
   - Shear Modulus
   - Density
   - Thermal Coefficient
   - Damping Ratio

The corresponding dialog for the material constant opens.

4. Either:
   - select a predefined material constant value for a built-in material name: Aluminum, Concrete, or Steel
   - select the Enter Value option and type a value for the material constant

5. Select the To Selection option to limit the assignment to the selection set.

6. Click OK.

- TR.26.2 Specifying Constants for Members and Elements (on page 2503)

M. Member Orientation

Related Links
- M. To change a beam incidence (on page 892)

M. To assign a member rotation angle

To assign an arbitrary member rotation angle about its longitudinal axis, use the following procedure. The rotation of a member about it's longitudinal axis is referred to as the "beta angle" in STAAD.Pro.

1. Select one or more members in the view window.
2. On the Specification ribbon tab, select the Beam > Beta Angle tool in the Specifications group.

The Beta Angle dialog opens.

3. Select the Angle in Degrees option and then type the angle of rotation.
4. Select the To Selection option.
M. To align a single angle to its flanges

To orient a single angle member aligned to its flanges, use the following procedure.

1. Select one or more members with single angle profiles in the view window.
2. On the Specification ribbon tab, select the Beam > Beta Angle tool in the Specifications group.

The Beta Angle dialog opens.

3. Select the option to align the flanges (i.e., geometric axis):

<table>
<thead>
<tr>
<th>To align...</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>the long leg with the local y axis (ST angles)</td>
<td>select the Angle option. This will rotate the angle section by $90^\circ - \alpha$.</td>
</tr>
<tr>
<td>the short leg with the local y axis (ST angles)</td>
<td>select the RAngle option. This will rotate the angle section by $180^\circ - \alpha$.</td>
</tr>
</tbody>
</table>

where

$$\alpha = \text{the angle between the principle axis system and the geometric axis (i.e., parallel to the flange faces) system of the single-angle profile}$$

Note: The orientation with the local y axis is for ST angles. RA angles are defined as being rotated $90^\circ$ and thus the Angle and RAngle options similarly rotate from that initial orientation.

4. Select the To Selection option.

Tip: The To View option assigns the specification to all members in the view window.

5. Click OK.
Table 42: Effect of BETA ANGLE and BETA RANGLE commands

<table>
<thead>
<tr>
<th>BETA value =</th>
<th>Zero (0)</th>
<th>ANGLE</th>
<th>RANGLE</th>
</tr>
</thead>
<tbody>
<tr>

- Beta Angle dialog (on page 2978)

M. To align a member to a reference point

To orient a member to an existing node or arbitrary point, use the following procedure.

1. Select one or more members in the view window.
2. On the Specification ribbon tab, select the Beam > Beam Reference Point tool in the Specifications group.

   The Referene Point dialog opens.

3. Select the type of point to use as a reference for orientation:
   - **To orient by...**
   - **Select the following...**
   - an arbitrary point in space
     select the Point option and define the coordinates with respect to the model origin
To orient by...

- **a vector from the member start node**
  - select the **Vector** option and then define the second point of the vector coordinates with respect to the member start node
- **a node in the model**
  - select the **Node** option and then select the node number from the drop-down list

4. Select the **To Selection** option.

   **Tip:** The **To View** option assigns the specification to all members in the view window.

5. Click **OK**

**Related Links**
- *TR.26.2 Specifying Constants for Members and Elements* (on page 2503)
- *G.4.3 Relationship Between Global and Local Coordinates* (on page 2301)

- *TR.26.2 Specifying Constants for Members and Elements* (on page 2503)

**M. Member Specifications**

**M. To add a member specification**

To add a specification for beam members in your model, use the following procedure.

   **Tip:** As with most assignment options, you can select a set of objects prior to starting this procedure and make the assignments to this selection set by using the dialog's **Assign** button.

Member specifications are used to assign beam members as cables, truss, tension- or compression-only. Similarly, additional specifications for member end offsets, fireproofing, and inactive members can be assigned.

1. Select the **Specifications** page in the Analytical Modeling page control bar.
   - The **Specifications - Whole Structure** dialog opens.
2. In the **Specifications - Whole Structure** dialog, click **Beam**.
   - The **Member Specification** dialog opens.
3. Select the dialog tab corresponding to the member specification you want to add:
   - Release
   - Offset
   - Property Reduction Factor
   - Cable
   - Truss
   - Compression
   - Tension
   - Inactive
   - Fire Proofing
   - Imperfection
4. Either:

To...

<table>
<thead>
<tr>
<th>Do the following...</th>
</tr>
</thead>
<tbody>
<tr>
<td>add the specification to the model for later assignment</td>
</tr>
<tr>
<td>add the specification to the model and assign to the current member selection</td>
</tr>
</tbody>
</table>

The dialog closes.

The member specification is added to the **Specifications - Whole Structure** dialog and the **Specification Values** table.

You can repeat this procedure as many times as necessary to add additional member specifications to your model.

If you did not assign the specification to a selection set, you must select the specification in the **Specifications - Whole Structure** dialog and assign it using one of the assignment methods.

**Related Links**
- **Specifications - Whole Structure dialog** (on page 2959)
- **Member Specification dialog** (on page 2962)

---

**M. To assign axial action members**

To assign a member as compression-only, tension-only, or a truss (axial-only) member, use the following procedure.

STAAD.Pro allows you to specify the axial actions of members.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam** tool in the **Specification** group.

A list of member specification types opens.

3. Select the specification type you want to assign:
   - **Compression Only** – members are capable of carrying compression forces only
   - **Tension Only** – members are capable of carrying tensile forces only
   - **Truss** – members are capable of carrying axial forces only

   **Note:** These member specifications have no additional parameters.

The **Member Specification** dialog opens to the corresponding tab.

4. Either:
To...
add the specification to the model and assign to the current member selection   click Assign.
add the specification to the model for later assignment   click Add.

The dialog closes.

The member specification is added to the Specifications - Whole Structure dialog and the Specification Values table.

Related Links
• *G.8.1 Truss and Tension- or Compression-Only Members* (on page 2330)
• *TR.23.1 Member Truss Specification* (on page 2492)

• *Member Specification dialog* (on page 2962)

M. To assign member end release

To assign a member end release or partial member end release, use the following procedure.

Release specifications are created for each of a member separately. To release both ends, you must create two specifications.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the Specifications ribbon tab, select the Beam > Release tool in the Specifications group.

   The Member Specification dialog opens to the Release tab.
3. Select which location on the member to which the release applies: Start or End.
4. Select the Release Type:

   Partial Moment Release
   
   or
   
   Release

5. For Partial Moment Release, select the directions which are partially released and the release ratio:
   a. Check the boxes corresponding to the directions of release.
      Check MP to assign the same partial moment release in all three local directions. Check a combination of MPX, MPY, and MPZ to apply different partial moment releases in each direction.
   b. For each direction checked, type a release ratio.
      This is a ratio between 0 and 1, where 0 indicated full moment restraint and 1 indicates full release.

6. For full Release, check the release directions which apply.
   These are FX, FY, FZ, MX, MY, and MZ. Any directions not checked will be fully restrained in that degree of freedom.

7. (Optional) To specify a spring in any degree of freedom, check the corresponding Release spring direction and type a spring constant in the adjacent field (in the indicated units).
   Springs can be applied to partial moment release or release types.
8. Either:
To…

<table>
<thead>
<tr>
<th>To…</th>
<th>Do the following…</th>
</tr>
</thead>
<tbody>
<tr>
<td>add the specification to the model and assign to the current member selection</td>
<td>click Assign.</td>
</tr>
<tr>
<td>add the specification to the model for later assignment</td>
<td>click Add.</td>
</tr>
</tbody>
</table>

The dialog closes.

**M. To assign member end offsets**

To assign a rigid end offset to one end of a member, use the following procedure.

Member end offsets can be used to model any situation where the end of the actual member does not coincide with the analytical node used for the member end incidence. For example,

- working points that do not align (e.g., a gusset plate connection)
- rigid end zones (e.g., a beam that connects to the flange of a stiff column)
- modeling top of steel (e.g., the center line of a beam that supports a slab)

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam > Offset** tool in the **Specification** group.

The **Member Specification** dialog opens to the **Offset** tab.

3. Select which **Location** on the member to which the offset applies: **Start** or **End**.
4. Select which **Direction** reference to use for the offset values: **Global** or **Local**.
5. Type the **Offsets** to use along each of the **X**, **Y**, and **Z** axes.
6. Either:

To…

<table>
<thead>
<tr>
<th>To…</th>
<th>Do the following…</th>
</tr>
</thead>
<tbody>
<tr>
<td>add the specification to the model and assign to the current member selection</td>
<td>click Assign.</td>
</tr>
<tr>
<td>add the specification to the model for later assignment</td>
<td>click Add.</td>
</tr>
</tbody>
</table>

The dialog closes.

- *Member Specification dialog* (on page 2962)

**M. To assign member imperfection for members**

To assign member drift or camber for use with an imperfection analysis, use the following procedure.
1. (Optional) Select the members which will all have the same member specification assigned.

2. On the **Specification** ribbon tab, select the **Beam > Imperfection** tool in the **Specification** group.

   ![Image]

   The **Member Specification** dialog opens to the **Imperfection** tab.

3. Do either of the following:
   
   select **Camber** to define the maximum offset along a beam from a line connecting the end points (typically for beams)
   
   or
   
   select **Drift** to define the offset at the end of a member (typically for columns)

4. Select the **Local Direction** of the imperfection and then type the **Value**, which is taken as a ratio of the member length to offset (i.e., L/d).

5. (Optional) For Camber, type a **Respect** value which is used to determine when to skip camber imperfection calculations.

   This ratio results in the camber imperfection calculations being skipped when:
   
   - the compressive load is small,
   - the member stiffness ($EI$) is large, or
   - the member is short

6. Either:

   **To...** 
   
   **Do the following...**
   
   - add the specification to the model and assign to the current member selection 
     
     click **Assign**.
   
   - add the specification to the model for later assignment
     
     click **Add**.

   The dialog closes.

You must assign the member imperfection specification to one or more members. An imperfection analysis is required in order to perform these calculations.

**M. To assign nonlinear cable members**

1. (Optional) Select the members which will all have the same member specification assigned.

2. On the **Specification** ribbon tab, select the **Beam > Cable** tool in the **Specification** group.

   ![Image]

   The **Member Specification** dialog opens to the **Cable** tab.

3. (Optional) Do either of the following:
select the **Initial TENSION** option and then type a value for the tension force in the cable

or

select the **Unstressed TENSION** option and then type a value for the initial length of the cable

If no value is given for either option, then a minimal cable tension is assumed.

4. Type a ratio value for one or more of the **Factor in global X : Fwx**, **Factor in global Y : Fwy**, or **Factor in global Z : Fwz**.

**Note:** These loads are used for Advanced Cable Analysis only.

The values are a multiplier of the self weight of the cable, applied in the selected global direction.

5. Either:

   **To...**                 **Do the following...**
   
   - add the specification to the model and assign to the current member selection
     
     click **Assign**.
   
   - add the specification to the model for later assignment
     
     click **Add**.

The dialog closes.

- **Member Specification dialog** (on page 2962)

---

**M. To assign cracked section properties to a member**

To assign reduced section property factors to a member, use the following procedure.

Global reduction factors will be applied to any member, regardless of material. Code-specific reduction factors are only applied to concrete members (non-concrete members included in the assignment are ignored).

**Note:** Automated stiffness reduction analysis is not supported by the basic solver. STAAD.Pro Advanced is required for this feature.

**Note:** For reducing the stiffness of a steel member for direct analysis per AISC 360, it is recommended use the REDUCEDEI parameter in the steel design parameters instead.

**Notes:** Reduction factors are considered for analysis only but not for design.

Results using the reduced section properties are not available when using the member query feature.

1. (Optional) Select the members which will all have the same member specification assigned.

2. On the **Specification** ribbon tab, select the **Beam > Cracked Property** tool in the **Specification** group.

   ![Member Specification dialog](image)

   The **Member Specification** dialog opens to the **Property Reduction Factors** tab.

3. Select either:

   **Global** – specify the **Reduction Factors** to be used below, which will apply to any member regardless of material.
or

**Code Specific** – select the building code to use reduction factors specific to load cases per that code which are only applied to concrete members:

**IS1893 2016**

4. Type the reduction factor values to assign to the current member selection:

- Reduction Factor for Cross sectional Area (RAX)

  **Note:** For IS1893 2016 reduction factors, the RAX input field is inactive as this property reduction is not mandated by that code for concrete members.

- Reduction Factor for Torsion Constant (RIX)
- Reduction Factor for Moment of Inertia, major axis (RIY)
- Reduction Factor for Moment of Inertia, minor axis (RIZ)

  **Note:** Reduction factor values should be between 0 and 1 (inclusive).

5. Either:

   - To... 
   - Do the following...

     - **add the specification to the model and assign to the current member selection**
     - **click Assign.**

     - **add the specification to the model for later assignment**
     - **click Add.**

The dialog closes.

**Notes:** Reduction factors are considered for analysis only but not for design.

Results using the reduced section properties are not available when using the member query feature.

**Related Links**

- **Member Specification dialog** (on page 2962)

**M. To assign member fire proofing**

To assign fire proofing to a member, use the following procedure.

**Tip:** Fire proofing thickness is specified in the current units of distance. You may want to change the units to a convenient value before beginning.

The fire proofing specification allows the program to automatically calculate the weight of the fire proofing material applied to members.

1. (Optional) Select the members which will all have the same member specification assigned.
2. On the **Specification** ribbon tab, select the **Beam > Fire Proofing** tool in the **Specification** group.
The **Member Specification** dialog opens to the **Fire Proofing** tab.

3. Select the **Fire Proofing Type**:
   - **BFP (Block Fireproofing):**
     The fire-protection material forms a rectangular block around the steel section. The thickness specified is the minimum thickness which defines the outer block dimensions.
     ![](image1)
   - **CFP (Contour Fireproofing):**
     The fire-protection material forms a coating around the steel section. The thickness specified is a constant thickness around the section profile.
     ![](image2)

4. Type the **Thickness** of the fire proofing in the units indicated.
5. Type the **Density** of the fire proofing material.
6. Either:
   - **To...**
   - **Do the following...**
     - add the specification to the model and assign to the current member selection
       - click **Assign**.
     - add the specification to the model for later assignment
       - click **Add**.

   The dialog closes.

**Related Links**
- TR.20.9 Applying Fireproofing on members (on page 2482)
- Member Specification dialog (on page 2962)

**M. To assign specifications to physical members**

To assign member end or axial specifications to physical members, use the following procedure.

Physical members can have member end releases, member end offsets, and truss specifications. Other analytical member specifications do not apply to physical members.
Note: For a physical member whose physical member specification is already assigned, the individual analytical members in that Physical member will adopt the same member specification that of the physical member. However, in case, where the analytical member specification is assigned to any member in that physical member, then this analytical member specification will supersede physical member specification.

2. On the Geometry ribbon tab, select the Toggle Physical Member Mode tool in the Physical Members group.
   
   The tool is highlighted to indicate the mode is active.
   
   Note: The dialog only shows three tabs in the physical modeling mode.
4. Select the specification type you want to assign:
   
   Release – one or more degrees of freedom are free or partially restrained at one end of the member
   
   or
   
   Offset – a rigid offset is present between one end of the member and the joint
   
   or
   
   Truss – members are capable of carrying axial forces only
5. Add Release or Offset attributes as you would for analytical members.
   
   a. Select the Location on the member: Start or End.
   
   b. For a Release, select if either partial or full release and the degrees of freedom of the release.
   
   c. For an Offset, select the directions of the offset.
6. Click Add.

M. Plate Specifications

M. To align a plate to a reference point

To orient the local axis of a plate element towards or away from an arbitrary point, use the following procedure.

The local z axis of the plates will remain perpendicular to the plane of the elements. This tool will simply orient the local axis such that this z axis points generally toward or away from the specified reference point. Refer to Plate Element Local Coordinate System (on page 2308) for additional details.
1. Select one or more plates in the view window.
2. On the Specification ribbon tab, select the Plate > Plate Reference Point tool in the Specifications group.

   The Plate Reference Point dialog opens.

3. Specify the X, Y, and Z coordinates of an arbitrary reference point.
4. Select if the Local Z Axis of the elements should point towards or away from the reference point.

   ![Diagram of plate reference point](image)

   *Figure 115: The local z axis of the plate is perpendicular to the plane of the element*

5. Select the To Selection option.

   **Note:** The To View option assigns the specification to all plates in the view window.

6. Click OK

**Related Links**

- G.5.1 Plate and Shell Elements (on page 2308)
- Plate Reference Point dialog (on page 2981)

**M. To specify plate thickness**

To specify the thickness of a plate element, use the following procedure.

1. Select the plates which will have a similar thickness.
2. On the Specification ribbon tab, select the Plate Thickness tool in the Plate Profiles group.

   The Properties - Whole Structure and the Plate Element/ Surface Property dialogs open.
3. Select the Plate Element Thickness tab.
4. Type the thickness values for the plate:
   
   **For a...**  **Do this...**
   
   uniform plate thickness  type the thickness in the Node 1 field. The other node fields will use this value by default
   
   linearly varying thickness  type the thickness of the plate at each corner node in the corresponding field

5. (Optional) Check the **Material** option and select the material definition from the drop-down list.
6. Either:
   
   click **Assign** to assign the thickness (and optional material) to the selection set
   
   or
   
   click **Add** to add the thickness property to the model for assignment later

**Related Links**

- *G.5.1 Plate and Shell Elements* (on page 2308)
- *TR.21.1 Element Property Specification* (on page 2487)
- *Plate ElementProperty dialog* (on page 2981)

**M. To assign plate corner release**

To release degrees of freedom of a plate element corner node, use the following procedure.
Releases are created for each node (by reference order) separately. To release multiple corners, you must create multiple specifications.

1. (Optional) Select the plates which will have the same plate release specifications assigned.
2. On the Specification ribbon tab, select the Plate > Release tool in the Specifications group.

   The Plate Specs dialog opens to the Release tab.
3. Select which Node to which the release applies.
   These are based on the local coordinate system for the element.
   
   **Tip:** To quickly identify the order of element corners, use the Plate Cursor tool and double click a plate. The Plate query dialog displays the nodes in order on the Geometry tab.
4. Check the Release directions.
   These are FX, FY, FZ, MX, MY, and MZ. Any directions not checked will be fully restrained in that degree of freedom.
5. Either:
   
   **To...**
   
   **Do the following...**
   
   add the specification to the model and assign to the current plate selection  
   click Assign.
   
   add the specification to the model for later assignment  
   click Add.

   The dialog closes.

- [TR.22.2 Element Release Specification](on page 2490)

**M. To assign plates as plane stress**

To assign plate elements as plane stress elements, use the following procedure.

This specification results in plates that only resist stress within the plane of the plate, but resist no out-of-plane bending. These plate elements are analogous to truss members.

   **Tip:** You can also assign this plate specification from the Plate Specs dialog, which opens when you click Plate on the Specifications - Whole Structure dialog.

1. Select the plates which will be plane stress elements.
2. On the Specification ribbon tab, select the Plate > Plane Stress tool in the Specifications group.

   The Plate Specs dialog opens to the Plane Stress tab.
Note: There are no parameters to provide for this plate specification.

3. Either:
   
   To... Do the following...
   
   add the specification to the model and assign to the current plate selection click Assign.
   
   add the specification to the model for later assignment click Add.

   The dialog closes.

Related Links
- G.5.1 Plate and Shell Elements (on page 2308)
- Plate Specs dialog (on page 2967)
- TR.24 Element Plane Stress and Ignore Inplane Rotation Specification (on page 2498)

M. To assign inplane rotation behavior to plates

To specify either no inplane rotational stiffness or completely rigid inplane rotational stiffness, use the following procedure.

Typically, the plate element used in STAAD.Pro has a very “soft” in-plane rotational, Mz, stiffness. There may be circumstances where this rotation should be ignored entirely (that is, with zero in-plane rotational stiffness). Alternatively, there may be circumstances where a rigid body rotation is required in plate elements.

1. Select the plates which will have the same inplane rigidity.
2. On the Specification ribbon tab, in the Specifications group, select either:

   To... Select this tool...
   
   ignore the in-plane rotation actions of the plates Plate > Ignore Inplane Rotation
   
   treat the plates as rigid bodies for in-plane rotation Plate > Rigid Inplane Rotation

   The Plate Specs dialog opens to the corresponding tab.

   Note: There are no parameters to provide for this plate specification.

3. Either:
   
   To... Do the following...
   
   add the specification to the model and assign to the current plate selection click Assign.
   
   add the specification to the model for later assignment click Add.

   The dialog closes.

Related Links
- G.5.1 Plate and Shell Elements (on page 2308)
- Plate Specs dialog (on page 2967)
- TR.24 Element Plane Stress and Ignore Inplane Rotation Specification (on page 2498)
M. To ignore plate stiffness

To ignore the stiffness of a selection of plates, use the following procedure.

A plate element whose stiffness is ignored by the program acts will distribute any element loads but the stiffness of the plate does not contribute to the stiffness of the structure. In this way, plate elements can be used to model non-structural components, such as glass cladding.

Tip: You can also assign this plate specification from the **Plate Specs** dialog, which opens when you click **Plate** on the **Specifications - Whole Structure** dialog.

1. Select the plates which will have their stiffness ignored by the program.
2. On the **Specification** ribbon tab, select the **Plate > Ignore Stiffness** tool in the **Specifications** group.

The **Plate Specs** dialog opens to the **Ignore Stiffness** tab.

**Note:** There are no parameters to provide for this plate specification.

3. Either:
   - To...                        Do the following...
     - add the specification to the model and assign to the current plate selection
       - click **Assign**.
     - add the specification to the model for later assignment
       - click **Add**.

The dialog closes.

**Related Links**
- *G.5.1 Plate and Shell Elements* (on page 2308)
- *Plate Specs dialog* (on page 2967)
- *TR.22.3 Element Ignore Stiffness* (on page 2491)

M. Node Specifications

M. To assign a rigid link between nodes

To create a rigid link between a master node any number of subordinate nodes, use the following procedure.

A master/slave specification establishes a primary node and a set of one or more subordinate nodes (i.e., “slave nodes”). Any displacements or rotations along the specified direction at the primary node will be directly translated to the subordinate nodes.

1. Select the nodes that will be the subordinate nodes.
2. On the **Specifications** ribbon tab, select the **Nodes Add Master/Slave Specification** tool in the **Specifications** group.
The Node Specification dialog opens to the Master/Save tab.

3. Select the Master Node number from the drop-down list of nodes.

4. Select a rigid link specification in the Slaved Directions:
   - Rigid link type Select...
   - in all directions the Rigid option
   - within a plane either the XY, YZ, or XZ option, corresponding to the plane
   - in specified degrees of freedom the specific degrees of freedom which are linked between the primary and subordinate nodes: FX, FY, FZ, MX, MY, and MZ

5. Either:
   - To add the specification to the model and assign to the current node selection click Assign.
   - add the specification to the model for later assignment click Add.

The dialog closes.

Related Links
- G.14 Rigid Diaphragms (on page 2336)
- TR.28.1 Master/Slave Specification (on page 2525)
- Node Specification dialog (on page 2960)

M. To assign nodes to a floor diaphragm

To define nodes that make up a floor diaphragm, use the following procedure.

Tip: Diaphragm heights and optional ranges are given in the current units of length. You may want to change the units of length to a convenient value before defining the diaphragm.

In order to generate the center of gravity for a diaphragm, you must create a mass load case which includes the weights to be considered for the diaphragm.

1. (Optional) Select a set of nodes which will be used to define the diaphragm.
2. Select the Specifications page in the Analytical Modeling page control bar.
   The Specifications - Whole Structure dialog opens.
   The Node Specification dialog opens.
4. Select the Floor Diaphragm tab.
5. Specify the floor level of the diaphragm by either:
   - selecting Height and then typing the height of the floor (Y coordinate value)
   - or
   - selecting YRange and then typing the Minimum and Maximum values of the diaphragm (Y coordinates)
6. (Optional) Select the Define Floor Range option to specify a boundary in the XZ plane of the diaphragm to define its edges:
select the **Select Nodes** option to either assign the diaphragm to the current node selection or to assign it later

or

select the **Floor Range** option to type maximum and minimum values in the global X and Z directions to bound the diaphragm.

Nodes lying outside of this selection or range will not be considered to be part of the diaphragm even if they are at the diaphragm height.

7. (Optional) You can specify a master node to use as the center of gravity by selecting the **Select Master Node** option and then selecting the node number to use as the center of gravity.

Otherwise, the program will calculate the center of gravity location for the diaphragm and add an analytical node at this location.

**Tip:** To report calculated CGs, add the Cg (Center of Gravity) option in the Post-Analysis Print Commands.

8. Either:

To... Do the following...

add the specification to the model and assign to the diaphragm to the current nodes click **Assign**.

add the specification to the model for later assignment or to use all nodes at the specified Height click **Add**.

The dialog closes.

**Note:** Soft story checks can be made for structures with rigid floor diaphragms per the IS 1893 2002, IS 1893 2016, and ASCE 7 specifications.

**Related Links**

- *TR.28.2 Floor Diaphragm* (on page 2526)

**M. Supports**

This section describes how to create boundary conditions for your model.

Select the **Supports** page in the in the **Analytical Modeling** workflow to open the **Supports - Whole Structure** dialog.

In STAAD.Pro, you will create support types that can be assigned to multiple nodes.

**M. To assign a fixed or pinned support**

To specify a node as either a fixed or pinned support, use the following procedure.

A fixed support is restrained against movement (translation and rotation) in all degrees of freedom. A pinned support is restrained against translation only, but is otherwise free to rotate. Refer to *Description of Pinned and Fixed* (on page 2514) for additional details.

1. Select the nodes that will have the same support condition.
2. On the Specifications ribbon tab, select one of the following tools in the Supports group:

![Fixed Support](image)

or

![Pinned Support](image)

3. The Create Support dialog opens to the corresponding tab.

4. Either:

   To...  
   
   add the support type to the model and assign to the current node selection  
   click Assign.

   add the support to the model for later assignment  
   click Add.

The dialog closes.

Related Links

- G.13 Supports (on page 2335)
- Create Support dialog (on page 2983)
- Supports - Whole Structure dialog (on page 2982)
- TR.27.1 Global Support Specification (on page 2514)

M. To assign an enforced support

To assign a support which can have a support displacement imposed as a load, use the following procedure.

In STAAD.Pro, a special support type is used for supports that will have an imposed displacement as part of a load case. These are called “enforced” supports.

**Note:** If no support displacements are defined for an enforced support, then this support behaves as a fixed support (i.e., no translation or rotation). Similarly, an enforced but support behaves like a corresponding fixed but support if no support displacements are defined.

1. Select the nodes that will have the same support condition.
2. On the Specifications ribbon tab, select the Other Supports tool in the Supports group.
3. Select one of the drop-down support types as follows:

<table>
<thead>
<tr>
<th>Support condition...</th>
<th>Select the following other support...</th>
</tr>
</thead>
<tbody>
<tr>
<td>fixed in all degrees of freedom</td>
<td>Enforced</td>
</tr>
<tr>
<td>released in one or more degrees of freedom</td>
<td>Custom Enforced</td>
</tr>
</tbody>
</table>

To impose a displacement on a joint with releases (e.g., a “pinned” support), you must use a custom enforced (i.e., ENFORCED BUT) support type and define the released degrees of freedom.

The Create Supports dialog opens to the corresponding tab.

4. (Optional) For an enforced but support type, check the Releases for this support type.
   For example, to create a “pinned” type support, you would check the MX, MY, and MZ release options.

5. Either:
To...

add the support type to the model and assign to the current node selection  
add the support to the model for later assignment

Do the following...

click Assign.

click Add.

The dialog closes.

You must create a load case with support displacements defined at nodes with enforced or enforced but support types assigned in order for this support type to have an effect on your model beyond behaving as a corresponding fixed or fixed but support.

Related Links

• G.13 Supports (on page 2335)
• EX. US-24 Analysis of a Concrete Block Using Solid Elements (on page 4552)

• TR.27.1 Global Support Specification (on page 2514)
• Create Support dialog (on page 2983)

M. To assign custom release supports

To assign a set of custom releases to a supported node, use the following procedure.

1. Select the nodes that will have the same support condition.
2. On the Specifications ribbon tab, select the Custom tool in the Supports group.

The Create Supports dialog opens to the Fixed But tab.

3. In the Releases group, check the degrees of freedom to be released for this support type.

   Note: If a spring constant is specified in a direction, then the corresponding degree of freedom cannot be released. A given support type can have a mix of releases and springs, but only in different degrees of freedom.

4. Either:

   To...

   add the support type to the model and assign to the current node selection  
   add the support to the model for later assignment

   Do the following...

   click Assign.

   click Add.

The dialog closes.

M. To assign a spring support

To assign a linear spring in one or more degrees of freedom to a support, use the following procedure.

You may want to change the system of input units to convenient values for your spring constants before creating a spring support type.

In STAAD.Pro, linear spring constants are specified as part of “fixed but” support types.
1. Select the nodes that will have the same support condition.
2. On the Specifications ribbon tab, select the Custom tool in the Supports group.

The Create Supports dialog opens to the Fixed But tab.

3. In the Define Springs group, type the linear spring constant to use for each translational and rotational spring direction.

   - **KFX** - translation in the global x direction
   - **KFY** - translation in the global y direction
   - **KFZ** - translation in the global z direction
   - **KMX** - rotation about the global x axis
   - **KMY** - rotation about the global y axis
   - **KMZ** - rotation about the global z axis

   **Note:** If a spring constant is specified in a direction, then the corresponding degree of freedom cannot be released. A given support type can have a mix of releases and springs, but only in different degrees of freedom.

   For example, a fixed but support could have MX, MY, and MZ released as in a pinned support and also have spring constants defined in FX, FY, and FZ.

4. Either:
   - **To...**
     - add the support type to the model and assign to the current node selection
     - add the support to the model for later assignment
   - **Do the following...**
     - click Assign.
     - click Add.

   The dialog closes.

You can now assign tension-only, compression-only, or multi-linear springs to these same supported nodes if necessary.

**Related Links**
- G.13 Supports (on page 2335)
- EX. US-3 Soil Springs for Portal Frame (on page 4383)
- EX. UK-3 Soil Springs for Portal Frame (on page 4663)
- TR.27.1 Global Support Specification (on page 2514)
- Create Support dialog (on page 2983)

**M. To assign multilinear springs to spring supports**

To model varying resistance to external loads at a spring support, use the following procedure.

You must assign spring supports to nodes before assigning multilinear spring definitions. You may not use multilinear springs in a model that contains tension-only or compression-only springs.

You may want to change the system of input units to convenient values for your spring constants before creating a spring support type.
**Note:** Multilinear springs can only be used with a select set of analysis types. Each load case should be separated by a Change command as well. See TR.27.4 Multilinear Spring Support Specification (on page 2520) for details.

1. Select one or more nodes assigned with spring support types.
2. On the **Specifications** ribbon tab, select the **Other Supports > Multi-Linear Spring** tool in the **Supports** group.
   - The **Create Support** dialog opens to the **Multilinear Spring** tab.
3. In the table, type the Spring Stiffness constant which corresponds to a Displacement.
   - These should be in order starting with the minimum displacement (e.g., this may also be the largest negative displacement) to the maximum positive displacement. All spring constants should be zero or positive values.
4. Click **Assign**.

### To assign support springs as a one-way

To specify support supported nodes as capable of carrying only tension or compression, use the following procedure.

You must assign spring supports to nodes before assigning tension-only or compression-only spring definitions. You may not use tension-only or compression-only springs in a model that contains multilinear springs.

STAAD.Pro assumes that negative displacement is compression and positive displacement is tension.

1. Select one or more nodes assigned with spring support types.
2. On the **Specifications** ribbon tab, select the **One-way Spring** tool in the **Supports** group.

   - The **Create Support** dialog opens to the **Tension/Compression Only Springs** tab.
3. Select the load direction the support is capable of resisting:
   - Tension Only
   - or
   - Compression Only
4. Select the Spring Direction options for this support type:
   - KFX
   - KFY
   - KFZ

   **Note:** One-way action is for translational springs only.
5. Click **Assign**.

**Related Links**
- TR.27.5 Spring Tension/Compression Specification (on page 2522)
- Create Support dialog (on page 2983)
M. To assign an inclined support

To assign a support that acts inclined with respect to the global axis, use the following procedure.

You may want to change the length unit to a more convenient value if you are going to define an incline direction by coordinate or vector.

See Inclined Support Axis System (on page 2516) for details on how the reaction directions are determined from the reference coordinate.

1. Select the nodes that will have the same support condition.
2. On the Specification ribbon tab, select the Other Supports > Inclined tool in the Supports group. The Create Support dialog opens to the Inclined tab.
3. Select the method for specifying the Incline Reference Point:

   To use this reference…  Do…
   
an arbitrary point with respect to the supported node  select the Coordinate option and then type the relative global X, Y, and Z distances to the reference point
   
an arbitrary point with respect to the model origin  select the Ref option and then type the global X, Y, and Z coordinates
   
an existing node in the model  select the RefJt option and then select the node number from the drop-down list

   **Note:** If you select the Ref or RefJt options, then the orientation of the inclined support axis system may vary from node to node.

4. Select the Support Type to use.

   - **Pinned** - restrained against translation but free to rotate
   - **Fixed** - restrained in all degrees of freedom
   - **Fixed But** - released in specified degrees of freedom and can have spring constants assigned in restrained degrees of freedom
   - **Enforced** - restrained in all degrees of freedom and can have imposed support displacements assigned as loads
   - **Enforced But** - released in specified degrees of freedom and can have imposed support displacements assigned as loads

5. (Optional) For Fixed But support type, type linear spring constants to use as necessary.
6. For Fixed But or Enforced But support types, select the released degrees of freedom.
7. Either:

   To…  Do the following…
   
   add the support type to the model and assign to the current node selection  click Assign.
   
   add the support to the model for later assignment  click Add.

   The dialog closes.

**Related Links**

- **G.13 Supports** (on page 2335)
- **EX. US-19 Inclined Supports** (on page 4515)
To assign a foundation support

To automatically model a support using foundation parameters, use the following procedure.

Isolated footing dimensions and subgrade modulus values are specified in the current input units. You may want to change these to a convenient value before specifying a foundation support.

STAAD.Pro can take foundation parameters for footings or mat foundations and automatically model spring supports.

1. Select the nodes that will have the same support condition.
2. On the Specification ribbon tab, select the Foundation tool in the Supports group.

The Create Support dialog opens to the Foundation tab.

3. Select the Foundation type to model:
   - **Footing** - a rectangular, isolated footing (i.e., spread footing) area is used to model spring stiffness using the subgrade modulus
     or
   - **Elastic Mat** - the program calculates the influence area of the load and then calculates a spring stiffness based on this area using the subgrade modulus
     or
   - **Plate Mat** - the program calculates the influence area of the load within a specified plate and then calculates a spring stiffness based on this area using the subgrade modulus

For additional details on the foundation types and their applicability, refer to **TR.27.3 Automatic Spring Support Generator for Foundations** (on page 2517).

4. Select the Direction of the resistance of the spring supports.

   The directions X, Y, or Z generate a spring in that global direction. The other two global directions are fixed against translation and moment about the selected direction is also fixed. The directions X Only, Y Only, or Z Only generate a spring in that global direction only.

5. Type the Subgrade Modulus of the soil.

6. (Optional) For Elastic Mat or Plate Mat foundation types, check the option Print influence area of each joint to include this information in the output.

7. (Optional) For Elastic Mat or Plate Mat foundation types, select a nonlinear spring option if necessary:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>

M. Loading Your Model

Load items in STAAD.Pro follow the general assigning workflow: you will define the load items within a primary load case. Then you will assign these load items to structural objects.

M. Available Structural Load Specifications in STAAD.Pro

The program contains the following load specifications:

Response Spectrum

**Table 43: Codes available in STAAD.Pro with Response Spectrum loads**

M. To create a new primary load case

This procedure applies to the Loading page in the Analytical Modeling workflow.

1. Either:
select the **Primary Load Cases** tool in the **Loading** group on the **Loading** ribbon tab

or

select the **Load Cases Details** section on the **Load & Definitions** dialog and then click **Add**

The Add New Load Cases dialog opens.

2. Select the **Primary** tab.
3. (Optional) Type a Number for the load case.

   The program will increment the load case number based on existing load case numbers.
4. (Optional) Select the **Loading Type**.

   This selection is used when automatically generating load combinations. If you select a live load type, you may also indicated if the load is **Reducible per UBC/IBC**.
5. Type a **Title** used to easily identify this load case.
6. Click **Add**.

   The empty load case is added to the **Load Cases Details** list.

You must now add load items to this load case and assign them to objects in the structure.

You can edit the load case title and loading type by selecting the entry in the **Load Cases Details** list and then clicking **Edit** in the **Load & Definitions** dialog.

You can remove the load case (along with any associated load items) by selecting the entry in the **Load Cases Details** list and then clicking **Delete** in the **Load & Definitions** dialog.

**Related Links**
- **Create Primary Load Case dialog** (on page 3002)
- **TR.32 Loading Specifications** (on page 2650)

**M. Load Items**

Individual load items are added to primary load cases.

**M. To add selfweight load**

To add the calculated weight of the structure objects as a load item, use the following procedure.

You must create a primary load case first.

**Note**: The material definition or density constant is used for each member, element, or solid to determine the self weight load.

1. Either:

   **On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group**

   **Tip**: This will add the load item to the currently selected load group selected in the program status bar.
or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Selfweight > Selfweight Load** tab.

3. Select a global **Direction** for the selfweight.
   
   This is typically the “vertical” direction but can be any global direction.

4. Type a **Factor**.
   
   This is multiplier on the calculated weight of the structure objects. You do not need to use a load factor for ultimate strength design here, as that is typically applied to load combinations.
   
   **Note:** A positive value will act in the positive global direction, so you will typically use a negative value here for gravity loads (-1 being the most commonly used value).

5. Click **Add**.
   
   The load item is added to the selected load case.

You must assign the load items to structure objects.

**Tip:** As selfweight typically will act on all members, plates, etc., you can use the **Assign to View** option and click **Assign** to quickly assign this load item to all objects in the structure (assuming that you have all objects currently displayed in the view window).

**Related Links**

- [TR.32.9.1 Selfweight Loads](on page 2685)
- [Selfweight tab](on page 3007)

**M. To add a nodal load**

To add forces or moments that act at nodes, use the following procedure.

**Tip:** Nodal loads are also referred to as “Joint Loads” in the STAAD command reference.

1. Either:
   
   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.
   
   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   
   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Nodal Load > Node** tab.

3. Type the force and moment magnitudes acting in the global directions (with sign) applied at the same nodes.
   
   You can use any combination of forces and moments.

4. (Optional) To apply the load along an inclined coordinate system:
   
   a. Select the **Inclined Load?** option.
      
      The force and moment labels are updated with (’) to indicate that the loads and moments will act in the inclined axes.
b. Select the method of defining the reference point.
   - **Reference Node** - select an existing node number from the model. The global coordinates of that node are displayed as read-only.
   - **Absolute** - type the global coordinates of an arbitrary point to use as the reference.
   - **Relative** - type relative distances from the loaded joint to the reference point. These distances are measured along the global axes.

   **Tip**: To easily select a reference node with respect to an existing node, first use the **Reference Node** option to populate the fields with that node's coordinates. Then select the **Absolute** option to modify the values. For example, you can update the Y coordinate of an existing node to select a point directly above or below that node.

c. Type the global coordinates (Absolute) or distances (Relative) to the reference point.

5. Click **Add**.
   The load item is added to the selected load case.

**Related Links**
- Nodal Load tab (on page 3008)
- G.15.1 Joint Loads (on page 2337)
- TR.32.1 Joint Load Specification (on page 2651)

M. To add a support displacement

To add a support displacement to a supported node, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   **Tip**: This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.
   The **Add New Load Items** dialog opens.

2. Select the **Nodal Load > Support Displacement** tab.
3. Select the displacement **Direction**.
4. Either
   - type the **Displacement** distance for translations (i.e., Fx, Fy, or Fz directions).
   or
   - type the **Rotation** angle for rotations (i.e., Mx, My, or Mz directions).
5. Click **Add**.
   The load item is added to the selected load case.

**Related Links**
- G.15.7 Support Displacement Loads (on page 2342)
M. Member Load Items

M. To add a concentrated force or moment on members

To add either concentrated forces or members at a point along the length of a member, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select either:

   the **Member Load > Concentrated Force** tab

   or

   the **Member Load > Concentrated Moment** tab

3. Type the location along the length of the member to the concentrated load, \( d_1 \).
   This distance is measured from the start node of the member.

4. Type the lateral offset from the geometric centerline to the load, \( d_2 \).

5. Select the **Direction** option in which the load acts.
   Concentrated loads can be applied in the global or local coordinates.

6. Click **Add**.
   The load item is added to the selected load case.

Related Links

- **G.15.2 Member Load** (on page 2337)
- **TR.32.2 Member Load Specification** (on page 2653)
- **Member Load tab** (on page 3009)

M. To add a uniform load to members

To add a uniform force or moment along the full or partial member length, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select either:
   - the **Member Loads > Uniform Force** tab
   - or
   - the **Member Loads > Uniform Moment** tab

3. Type the magnitude of the distributed load (with sign), $W_1$.
4. Type the location along the length of the member to the start of the uniform load, $d_1$ and to the end of the uniform load, $d_2$.
   Both distances are measured from the start node of the member. If $d_2$ is zero, then the load will act to the end node of the member.
5. Type the lateral offset from the geometric centerline to the load, $d_3$.
6. Select the Direction option in which the load acts.
   Uniform loads can be applied in the global, local, or projected coordinates.
7. Click **Add**.
   The load item is added to the selected load case.

**Related Links**

- **G.15.2 Member Load** (on page 2337)
- **TR.32.2 Member Load Specification** (on page 2653)
- **Member Load tab** (on page 3009)

**M. To add a linear varying load to members**

To add linear varying force along the length of a member, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select :
   - the **Member Loads > Linear Varying** tab
   - or
   - the **Member Loads > Trapezoidal** tab

3. Select the load shape to apply:
   - **Load increases...**
   - select...  
     - **linearly along entire length of beam**
     - **the $W_1, W_2$ option on the Linear Varying** tab
Load increases... Select...
load increases from zero to peak at midspan and back to zero the W3 option on the Linear Varying tab
linearly along a partial section of the beam the Trapezoidal tab

4. Type the load values at the ends (W1, W2 option) or at midspan (W3 option) (with sign).
5. Select the Direction.
6. Click Add.
   The load item is added to the selected load case.

Related Links
• G.15.2 Member Load (on page 2337)
• TR.32.2 Member Load Specification (on page 2653)
• Member Load tab (on page 3009)

M. To add a prestress or post-tension load to members

To add a load due to prestressing or post-tensioning to members, use the following procedure.

1. Either:

   On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group
   
   Tip: This will add the load item to the currently selected load group selected in the program status bar.
   or
   In the Load & Definition dialog, select a primary load case in the Load Cases Details list and then click Add.
   The Add New Load Items dialog opens.

2. Select the loading Type:
   
   Prestress – prestress force is considered at the time of stressing and thus the force is transferred to the adjacent members or supports
   or
   Poststress - the prestress force is considered after the time of stress and thus the force is applied to the member itself (not transferred to the adjacent members or supports)

3. Type the prestress Force (in current units).

4. Type the Eccentricity Distances used to control the tendon profile at the Start, Middle, and End of the member.
   Eccentricities are measured in the local y axis (i.e., positive is “up” with respect to the local y axis). The cable profile is assumed to be parabolic (i.e, a “draped” tendon profile). Refer to G.15.5 Prestress and Poststress Member Load (on page 2340) for further details on how the tendon profile shape is calculated.

5. Click Add.
   The load item is added to the selected load case.

Related Links
• G.15.5 Prestress and Poststress Member Load (on page 2340)
• TR.32.5 Prestress Load Specification (on page 2678)
• Member Load tab (on page 3009)
M. To add fixed end member loads

To apply fixed end loads to ends of a beam, use the following procedure.

1. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

**Tip:** This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add.**

The **Add New Load Items** dialog opens.

2. Select the **Member Loads > Fixed End** tab.

3. Type the load values to apply at the **Start Node** and **End Node.**

   These reference the ends of the member but the loads are applied directly to the member ends, not the joints. These loads are given in terms of the member coordinate system and the directions are opposite to the actual load on the member.

4. Click **Add.**

   The load item is added to the selected load case.

**Related Links**

- **G.15.4 Fixed End Member Load** (on page 2340)
- **TR.32.7 Fixed-End Load Specification** (on page 2683)
- **Member Load tab** (on page 3009)

M. Plate, Surface, Area, and Solid Load Items

M. To add pressure load on a plate

To add a uniform pressure load over an entire plate or a rectangular portion of a plate, use the following procedure.

1. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

**Tip:** This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add.**

The **Add New Load Items** dialog opens.

2. Select either:

   - the **Plate Loads > Pressure on Full Plate** tab
   - or
   - the **Plate Loads > Partial Plate Pressure** tab
3. Type the magnitude of the uniform pressure (with sign), $W_1$.

4. For partial plate pressure loads, type the coordinates (with respect to the center of the element) to the first and second corners of the loaded rectangular area: $X_1, Y_1, X_2,$ and $Y_2$

![Figure 116: Coordinate values, x1,y1 & x2,y2, in the local coordinate system](image)

5. Select the **Direction** option in which the load acts.
   Pressure loads can act in any of the global directions: $GX$, $GY$, or $GZ$ as well as in the **Local Z** direction of the plate. Additionally, full pressure loads can act in the **Local Y** and **Local X** directions of the plate.

6. Click **Add**.
   The load item is added to the selected load case.

**Related Links**
- *G.15.8 Loading on Elements* (on page 2342)
- *Plate Loads tab* (on page 3013)
- *TR.32.3.1 Element Load Specification - Plates* (on page 2657)

**M. To add an area load**
To add an loaded area which distributes pressure to beams forming a closed loop, use the following procedure.

*Note: The AREA LOAD command has been deprecated in favor of the ONEWAY LOAD or FLOOR LOAD commands.*

1. Either:
   - On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.
   
   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   or
   - In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.
   The **Add New Load Items** dialog opens.

2. Type the magnitude of the **Pressure** in the current units.

3. Select the **Direction** in which the pressure acts.
- **Local Z** - parallel to the member local Z axis
- **GX** - parallel to the global X axis
- **GY** - parallel to the global Y axis
- **GZ** - parallel to the global Z axis

4. Click **Add**.
   The load item is added to the selected load case.

**Related Links**

- *G.15.3 Area, One-way, and Floor Loads* (on page 2338)
- *TR.32.4.1 Area Load Specification* (on page 2665)
- *Area Load tab* (on page 3012)

**M. To add a floor load or one-way load**

To generate a pressure load over a floor area using either two-way or one-way load distribution, use the following procedure.

1. Either:
   - On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group
     **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   - or
   - In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.
     The **Add New Load Items** dialog opens.

2. Select the **Floor Load** tab.

3. Either:
   - select a range option –XRANGE, YRANGE, or ZRANGE– and then type the upper and lower bound distances (i.e., range) to define the members which define this loaded floor
   - or
   - select the **Group** option to apply the load to a named group and then select the Member Group name from the list
     **Tip:** This can be used to select a Composite Deck to assign a floor load to an entire deck. When decks are formed, this automatically creates a new group with the same name.

4. Type the **Pressure** in the current units.
5. Select the **Direction** in which the load acts.
6. (Optional) Select the **One Way Distribution** option to distribute the load towards the longer supporting members (i.e., along the shorter load path).
7. (Optional) When applying the load to a Group, you can check the **Inclined Floor** option to instruct the program that the load is applied to a set of members that form panels inclined to one of the global planes.
8. (Optional) You can report the panel and load data the program calculates:
   - a. Check the **Print to output file** to have data included in the STAAD Output and then select the data to include there.
b. Check the **Print to external text file** to have the data included in an external file and then select the data to include there.

9. Click **Add**.
   The load item is added to the selected load case.

**Related Links**
- **M. Composite Decks** (on page 693)

- **G.15.3 Area, One-way, and Floor Loads** (on page 2338)
- **Floor Load tab** (on page 3012)
- **TR.32.4.2 One-way Load Specification** (on page 2666)
- **TR.32.4.3 Floor Load Specification** (on page 2672)

**M. To add a surface selfweight load**

To add a selfweight load for surface elements so the weight of the surface elements is included in the analysis of the structure, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Surface Loads > Selfweight Load** tab.

3. Select a global **Direction** for the selfweight.
   This is typically the “vertical” direction but can be any global direction.

4. Type a **Factor**.
   This is multiplier on the calculated weight of the structure objects. You do not need to use a load factor for ultimate strength design here, as that is typically applied to load combinations.

   **Note:** A positive value will act in the positive global direction, so you will typically use a negative value here for gravity loads (-1 being the most commonly used value).

5. Click **Add**.
   The load item is added to the selected load case.

   The SSELFwT command, along with direction and factor, are added to the load case.

   You must assign the load items to structure objects.

**Related Links**
- **TR.32.9.2 Surface Selfweight Load** (on page 2686)
M. To add a hydrostatic load to objects

To assign a hydrostatic load to members or plate elements, use the following procedure.

1. Either:
   - On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.
     Tip: This will add the load item to the currently selected load group selected in the program status bar.
   - or
     In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.
     The **Add New Load Items** dialog opens.

2. Select the appropriate tab:
   - **Object type**
     - **Members**
       - **Member Load > Hydrostatic**
     - **Plates**
       - **Plate Loads > Hydrostatic**

   Note: A message on the dialog indicates this option is disabled because no objects are selected.

3. Click **Select objects**.
   The **Selected Item(s)** dialog opens and the **Add New Load Items** dialog closes temporarily.

4. Use the appropriate selection tool to select all the objects to which you want to apply the hydrostatic load in the view window.
   All objects must be of the correct type to populate the list (e.g., only members can be added to the Member list, only plates can be added to the Plate list).

   Note: Hold the **<Ctrl>** to select multiple objects individually.
As objects are selected, their corresponding object id number is added to the object list.

5. Click **Done**.
   
The **Selected Item(s)** dialog closes and the **Add New Load Items** dialog re-opens. The selected objects are now displayed in the objects list.

6. Type values for the minimum and maximum global forces.

7. Select the direction in which the force acts and the global axis along which the program should interpolate loads.

8. Click **Add**.
   
The dialog closes and the hydrostatic load items are added to the selected load case.

Unlike most other loads, you do not need to assign these load items. The selection of the objects is used for assigning the load. The program will calculate the exact trapezoidal load pattern based on the other parameters.

**M. To calculate the structure frequency**

To calculate the frequency of the structure for a load case, use the following procedure.

Frequency calculation is made for a specific load case, so you must have at least one primary load case added to the input file.

This can be done by either the Rayleigh method or the eigenvalue extraction method. The latter can consider missing mass mode.

1. Either:
   
   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.

2. Select either:
   
   the **Frequency > Rayleigh Frequency** tab to use the approximation method
   
   or
   
   the **Frequency > Modal Calculation** tab to use the more exact eigenvalue extraction method

3. (Optional) For Modal Calculation, check the **Consider Missing Mass** option to include the missing mass procedure for steady state or harmonic analysis.

4. Click **Add**.
   
The frequency calculation is added to the load case.

**Related Links**

- *TR.34.1 Rayleigh Frequency Calculation* (on page 2790)
- *TR.34.2 Modal Calculation Command* (on page 2791)
M. Wind Loads

This section describes how to add wind loads to your STAAD.Pro model.

M. To add a wind load definition

To add a custom wind profile definition to your model, use the following procedure:

Wind load definitions describe the vertical wind profile that acts in a specific direction.

1. In the Load & Definition dialog, select the Definitions > Wind Load entry and then click Add.
   The Add new: Wind Definition dialog opens.
2. Type optional Comments and then click Add.
   The definition type is added to the Definitions > Wind Load entry in the Load & Definition dialog.
3. Either:
   - Repeat step 2 to add more wind definitions
   - or
   - click Close
4. Select the new wind definition type and click the Add.
   The Add New: Wind Definitions dialog opens. The dialog now displays the Intensity and Exposures tabs.
5. On the Intensity tab, select Custom in the Type drop-down list.
6. Enter the wind profile data in a specific direction in pressure and height above ground pairs.

   **Tip:** You can paste data copied from a spreadsheet.

   You can also parametrically calculate the wind profile based on ASCE 7. Refer to M. To add an ASCE 7 wind load definition (on page 836) for details.

   Alternatively, you can specify SNiP code wind parameters here. Refer to M. To add a SNiP wind load definition (on page 837) for details.
7. On the Exposure tab, type the Factor value.
   A value of 1.0 means that the wind force may be applied on the full influence area associated with the joint(s) if they are also exposed to the wind load direction.
8. Click Add.
9. (Optional) Repeat Steps 4, 7, and 8 to add additional exposure factors to this wind definition.
   You may add up to 99 exposure factors to a wind definition.

You must now apply this wind profile in a load case and specify the direction of the wind.

Related Links

- **G.16.3 Wind Load Generator** (on page 2345)
- **Create Wind Type Definition dialog** (on page 3038)
- **TR.31.3 Definition of Wind Load** (on page 2623)
M. To add an ASCE 7 wind load definition

To populate the wind intensity table with values calculated per ASCE 7, use the following procedure. These steps are performed when adding a wind load definition in the Add New: Wind Definitions dialog.

1. On the Intensity tab, select Custom in the Type drop-down list.
2. Click Calculate as per ASCE 7. The ASCE-7: Wind Load dialog opens.
3. On the Common tab, enter the general code and site information:
   a. Select the year (edition) of ASCE-7 code.
   b. Select the Building Classification Category.
   c. Type the Basic Wind Speed in the selected units.
   d. Select the Exposure Category.
   e. Select the Structure Type that best describes your structure.
   f. (Optional) If you need to Consider wind speed-up over Hills or Enscarpment, select the Yes option and then provide the rise type and dimensions
4. Click Apply.
   Note: The second tab of the dialog updates to reflect the Structure Type selection.
5. Select the second tab and enter the structure data:
   a. Type the structure dimensions.
   b. Select the structure cross-section type (where applicable).
   c. Select the orientation of members exposed to wind (where applicable).
   d. Select the shape of exposed structural members (where applicable).
   e. Type the Structure Natural Frequency.
   f. Type the Structure Damping Ratio.
   g. Select the Enclosure Classification (where applicable).
   h. (Optional) Select the Use Kzt or Use Kd options to manually type values for these coefficients. The calculated coefficients are otherwise used.
6. Select the Design Pressure tab.
   The height vs. intensity data calculated for the current input is displayed here.
7. (Optional) You can check the options for Use G and Use Cf to manually type values for these coefficients.
   The calculated coefficients are otherwise used.
8. Click OK.
   The dialog closes and the wind intensity at height data is added to the table on the Intensity tab.

Note: The input fill will contain a section on ASCE 7 wind load generation data. Though this is not read directly by the STAAD analysis engine, these values are stored to allow you to make changes to the wind load parameters.

You can now proceed with the wind load definitions using the calculated values per ASCE-7.

Related Links
- TR.31.3 Definition of Wind Load (on page 2623)
- ASCE 7 Wind Load dialog box (on page 3039)
To add a parametric wind load definition per the SNiP 2.01.07, SP 2.07.7, or SP 20.13330.2016 Loads and Actions building codes, use the following procedure.

**Tip:** Change units for convenience.

1. On the **Intensity** tab, select either of the following from the **Select Type** drop-down list:
   - SNiP 2.01.07-2011
   - SNiP 2.07.7-85
   The dialog updates to display the SNiP Parameter fields.
2. Type the **Wind Pressure**.
3. Select the **Terrain** type from the drop-down list.
4. Select the structure **Classification** from the drop-down list.
5. Select the **Region** from the drop-down list.
6. Type the **Delta** value.
7. Click **Add**.

**Related Links**

- **TR.32.12.3 Generation of Wind Loads** (on page 2779)
- **Add New Wind Definitions (data) dialog** (on page 3038)
- **Wind Load tab** (on page 3018)

**M. To assign exposure for joints**

To assign wind load definition exposure to joints, use the following procedure.

If your wind load definition has multiple exposure factors, you can specify the exact nodes for each factor this way.

This method assumes that you select the nodes first and then assign the exposure value to them. However, you can select the exposure method and then assign that to nodes using a different assignment method if more convenient.
1. Select the nodes which will all use a specific exposure ratio.
2. In the **Load & Definition** dialog, select that **Exposure** entry within a wind load definition.
3. Select the **Assign to Selected Nodes** method for assignment.
4. Click **Assign**.
   A message prompts you to confirm this assignment.
5. Click **Yes**.

The exposure ratio is assigned to these joints. When an exposure is selected, the assigned nodes are highlighted red in the view window.

You must now apply the wind load to the structure within a load case.

### M. To apply a wind load

To apply a defined wind load to your structure, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The Add New Load Items dialog opens.

2. Select the **Wind Load > Wind Load** tab.

   **Note:** If you have not previously added a wind load definition to the model, this tab is inactive. Refer to **M. To add a wind load definition** (on page 835) for details.

3. In the **Select Type** drop-down list, select the wind load definition for this load case.
4. Select the **Exposed Surface and Direction** of the load and then type the load **Factor** value.
5. (Optional) If the wind load definition is for a SNI code, specify the additional SNI Parameters:
   a. Select the option to **Apply Wind Load at Corners** if required.
   b. Select the configuration from the drop-down list.
   c. Type the wind pressure coefficient.
6. Specify the range of values over which the load applies. Type the along the global axis of how the wind load acts.
7. (Optional) Check the **Open Structure** option for truss, lattice, or other open structure types.
   This will apply the load only to the projected area of the members and joints, not to the bounded area of members or surfaces.
8. Click **Add**.

The program will automatically calculate the joint loads for structure that lies within the specified range. Selecting the wind load item in the **Load & Definition** dialog will highlight the loading members. The calculated surface exposure and the tributary areas will also be displayed for closed structures.
M. To apply a dynamic wind load per SP 20.13330.2016

To apply a SP 20.13330.2016 wind definition as a dynamic load to your structure, use the following procedure.

A modal analysis and at least one static load cases are required in order to use a dynamic wind load case.

In order to perform dynamic wind load generation in STAAD.Pro you must previously define a static load case. The static load case could be any primary static load case which is defined before the Russian dynamic load case, including a static wind loading per the same code. This static load case will provide static load vector to the dynamic wind load module.

As the Russian dynamic wind load component requires modal masses and eigen vectors to calculate the dynamic wind load component at nodes, modal analysis must be performed before the dynamic wind load definition. Therefore, you must also include a separate load case for modal analysis with reference mass defined before the load case. See G.17.3.2 Mass Modeling (on page 2365) for details. Alternatively, if the mass loads are not needed for use with other load cases (that is, a reference load case is not needed for other loads), then you may define the mass loads within the dynamic load case prior to the WIND LOAD command.

1. Either:

On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.

Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the Load & Definition dialog, select a primary load case in the Load Cases Details list and then click Add. The Add New Load Items dialog opens.

2. Select the Wind Load > Wind Load - Dynamic tab.

Note: If you have not previously added a SP 20.13330.2016 wind load definition to the model, this tab is inactive. Refer to M. To add a SNiP wind load definition (on page 837) for details.

3. In the Select Type drop-down list, select the wind load definition for this load case.

Only SP 20.13330.2016 wind definitions are present in this list.

4. Type the Width of building along wind dir. and Width of building across wind dir. values.

These are the width parallel and perpendicular to the wind direction, respectively.

5. Type the load Factor value.

6. (Optional) Check the Internal option to adjust the direction so that the wind acts as an internal pressure (i.e., suction on the surface).

7. (Optional) Check the Allow All Mode Shapes to include all mode shapes from the modal analysis.

Otherwise, only the first mode shape will be used.

8. Select the Static Wind Case from the drop-down list of primary load cases that precede this load case in the model.

9. Select the direction in which the wind is applied from the graphical plan view.

10. Click Add.

M. Seismic Loads

This section describes how to add seismic loads to your STAAD.Pro model.

M. To add a seismic load definition

To add seismic load parameters per a building code, use the following procedure.

Static equivalent seismic loads are applied based on a set of parameters used to define the load. The parameters vary for each building code.

2. On the Seismic Parameters tab, select the building code from the Type drop-down list.
3. (Optional) Check the Include Accidental Load option to consider accidental torsion.
   
   Note: Not applicable for the Canadian NRC 1995 code.
4. (Optional) For the Indian IS 1893-2002/2005 code:
   a. (Optional) Check the Include IS 1893 Part 4 option for industrial or stack-like structures.
   b. Click Generate to open the IS 1893 Seismic Parameters dialog, which provides a simpler method for entering the parameters with additional context for IS 1893 Part 1.
   c. Click Generate.
5. Type the seismic parameters in the table as required for the selected building code.
   A contextual note is displayed below the table for each parameter. Refer to TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2544) for detailed descriptions of the parameters for each code.
6. Click Add.
   If you have not provided all the required parameters, a message opens to alert you of missing items. Once the minimum required parameters have been provided, the seismic definition is added to the Definitions > Seismic Definitions entry in the Load & Definition dialog. The Seismic Parameters tab is removed from the Add New: Seismic Parameters dialog.

You will need to add weight items to the load definition. You can do this through a series of loads, a reference load case, or a combination of both.

Related Links
- TR.31.2 Definitions for Static Force Procedures for Seismic Analysis (on page 2544)
- TR.31.2.5 Chinese Static Seismic per GB50011-2001 (on page 2563)
- Add New Seismic Definitions dialog (on page 3044)

M. To add weight items to a seismic load definition

To create structural weights for a seismic load definition, use the following procedure.

If you want to assign floor weights to a floor group, you must have at least one group of the type Floor previously defined to use this option.
Tip: If you want to use the same loads for both seismic weights and another load (e.g., the dead load case), you can use a Reference Load case instead of this procedure.

1. Select the tab in the **Add New: Seismic Definitions** dialog corresponding to the weight you want to add.

2. Specify the weight parameters:
   For the following weight types, enter the data as indicated:
   
   **Weight type** | **Data to enter**
   --- | ---
   Self | Type a **Self Weight Factor**
   Joint | Type a **Joint Weight**
   Member | Select the **Loading Type**. Type the **Weight** to use, the **Starting Distance**, and for uniform weights, the **Ending Distance**.
   Element | Type a uniform **Pressure**

   For Floor Weights, do the following:
   a. Type a uniform floor **Pressure**.
   b. Select if the load is applied over a **Range** or a floor **Group**.
   c. (Optional) Check the **One Way Distribution** option to use that load distribution to supporting members.
   
   You can select the default behavior or select a specific member towards which the load is directed.
   d. For the **Range** option, specify Y range limits and optionally X and Z range limits.
   e. For the **Group** option, select a named group of members.
   f. (Optional) For the **Group** option, select the **Inclined Floor** option if the group includes members forming a panel that is inclined from the global XZ plane.

   Refer to [TR.32.4.3 Floor Load Specification](on page 2672) for additional details on specifying floor loads.

3. Click **Add**.
4. Repeat steps 1 through 3 to add additional weights to your seismic load definition.
5. Click **Close**.

You must assign the weight items to the appropriate objects.

**M. To add weight by a reference load to a seismic load definition**

To use a previously defined reference load case for the weights in your seismic load definition, use the following procedure.

You must create a reference load case containing the load items to be used as weights in the seismic load. Refer to [M. To create a reference load](on page 873) for details.

This approach is preferable if you need to use the same weight tables for multiple loads or analysis.

1. Select the **Reference Load** tab in the **Add New: Seismic Definitions** dialog.
2. Either:
   
   select a reference load definition and then click **>** to add it to the Reference Load item
   
   or
   
   click **>>** to add all the available reference load definition to the Reference Load item.
3. (Optional) Type a **Factor** to apply to each reference load definition in the Reference Load item as needed.
4. Select the global direction along which the load is applied from the **Along** drop-down list.
5. Click Add.
6. Click Close.

Related Links
• TR.31.6 Defining Reference Load Types (on page 2642)

M. To add a seismic load

To add a seismic load to a primary load case, use the following procedure.

1. Either:
   On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.
   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   or
   In the Load & Definition dialog, select a primary load case in the Load Cases Details list and then click Add.
   The Add New Load Items dialog opens.
2. Select the Seismic Loads tab.
   **Note:** If you do not have a seismic load definition created, this tab is disabled.
3. Select the global Direction in which this seismic load acts.
4. (Optional) Type the scale Factor to apply to the load.
5. (Optional) Check the option to use Multiplying factor for Accidental Torsion Moment and type a Factor.
   This value is the ratio of the total building width and is taken from the center of mass for each level.
6. (Optional) Check the option to use Multiplying factor for Natural Torsion Moment and type a Factor.
   **Note:** This is only applicable for structures modeled with a rigid diaphragm.
7. Click Add.

M. Response Spectra

This section describes how to add response spectra to your STAAD.Pro model.

**Tip:** In STAAD.Pro, a response spectrum analysis is performed on the model when it contains response spectra load case. It is possible to use a linear, elastic analysis with a response spectrum load.
M. To add a generic response spectrum

To add a custom response spectrum (referred to as the “generic” method) to your model, use the following procedure.

**Note:** You must enter in spectra values using the dialog. To reference an external file containing spectra data, you must use the STAAD.Pro Editor.

1. Either:
   - On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.
     - **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   - or
     - In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.
     - The **Add New Load Items** dialog opens.

2. Select the **Response Spectrum** tab.

3. Select **Custom** from the **Code** drop-down list.

4. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   **Note:** For the ASCE method, there are two optional parameters, FF1 and FF2, which can be checked and specified.

5. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.
   - The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an .acc file extension.

6. Specify the spectrum data:
   a. Select if the **Spectrum Type** uses **Acceleration** or **Displacement** values.
      - The spectrum data table updates accordingly.
   b. Type in the period and spectra data pairs in the table.
      - As you add pairs of data, the response spectrum plot is generated to help review the input.

7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.
   - The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.

8. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.

9. Select the directions which spectrum is applied and, for each, type a factor (0-1.0).

10. (Optional) You can apply each of the following optional steps as needed:
    a. Select one of the **Signed Response Spectrum Results Options** if needed:
       - check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.
       - or
check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

**b.** To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

c. Type a **Scale** factor to apply to the spectra data.

d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.

**Related Links**
- TR.32.10.1.1 Response Spectrum Specification - Custom (on page 2688)
- Response Spectra tab (on page 3021)

**M. To add an IBC 2000 response spectrum**

To specify a response spectrum for seismic loading per the IBC 20005 code, use the following procedure.

The period and acceleration or displacement values for an IBC 2000 response spectrum can be generated by the program to use with a “custom” response spectrum load.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Response Spectrum** tab.

3. Select **Custom** in the **Code** list.

4. Generate the IBC 2000 values for the table:

   **Note:** In order to use the generated spectrum values, you must leave the **Spectrum Type** selection as **Acceleration**.

   a. Click **Generate IBC Spectrum - 2000**.

   The **Spectrum Parameters** dialog opens.

   b. Specify the mapped acceleration values by either:

      select the **Zip** code from the drop-down list, click **Find Lat / Long**, and then click **Calculate S1 / SS**

   or
enter the **Latitude** and **Longitude** and then click **Calculate S1 / SS**

or

**enter the S1 and SS values directly**

c. **Select a Site Class** for the location.
   The Fa and Fv values for the site location are displayed.

d. **Type the Start, End, and Interval values for the period.**

e. **Click Generate Spectrum.**
   The Generated Spectrum: IBC 2000 dialog opens. The values are tabulated and the spectrum is plotted. You can use the settings on this dialog to review the data.

f. **Click Close.**
   The response spectrum values and plot is generated.

**Note:** If you select

5. **Select the Combination Method** to use to combine the responses from each mode into a total response.

   **Note:** For the ASCE method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.

6. **(Optional)** Check the **Save** option to create a file containing the joint accelerations in ratios of gravity and in radians/sec².
   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an .acc file extension.

7. **Select if the Interpolation Type** is **Linear** or **Logarithmic**.
   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.

8. **Select the Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.

9. **Select the directions which spectrum is applied and for each, type a factor (0-1.0).**

10. **(Optional)** You can apply each of the following optional steps as needed:

    a. **Select one of the Signed Response Spectrum Results Options** if needed:
       check **Dominant** and type a **Mode No** to use for determining the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

       or

       check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

    b. **To generate individual modal response load cases,** check the **Generate load case[s] for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.
       If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

    c. **Type a Scale factor to apply to the spectra data.**

    d. **Check the Missing Mass option** to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

    e. **If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead,** check the **ZPA** option and type a frequency.
If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.

   The new response spectrum is added to the currently selected load case.

**Related Links**
- *G.17.3.4 Response Spectrum* (on page 2371)
- *TR.32.10.1.1 Response Spectrum Specification - Custom* (on page 2688)
- *Spectrum Parameters dialog* (on page 3027)
- *Generated Spectrum dialog* (on page 3027)

**M. To add an IS 1893 response spectrum**

To specify a response spectrum for seismic loading per the IS 1893 code, use the following procedure.

1. Either:

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.

   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.

   The **Add New Load Items** dialog opens.

2. Select the **Response Spectrum** tab.

3. Select **IS-1893** in the **Code** list.

4. Specify the IS 1893 specific parameters:

   a. Select a **Subsoil class** for the location.

<table>
<thead>
<tr>
<th>Subsoil option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom</td>
<td>You must enter Period and Acceleration or Displacement value pairs in the table, based on the <strong>Interpolation Type</strong> selected. You can also select the <strong>Interpolation Type</strong> for values between data points.</td>
</tr>
<tr>
<td>Hard, Medium, or Soft Soil</td>
<td>Average response acceleration coefficient is calculated. You will not need to select <strong>Spectrum Type</strong> or <strong>Interpolation Type</strong> for these options.</td>
</tr>
</tbody>
</table>

   b. (Optional) Select the **Ignore mode(s) with mass participation (IGN)** option and then enter a percentage value.

   Local and torsional modes whose mass participation is less than this percent value are then considered negligible and therefore will be excluded.

   c. (Optional) Select the **Use Torsion** option and then enter the **Dynamic Eccentricity (DEC)** and **Accidental Eccentricity (ECC)** factors.

   The dynamic eccentricity factor is multiplied by the static eccentricity (i.e., the distance between the center of mass and center of rigidity) to get the dynamic eccentricity. This value should typically be 1.0 or higher.
The accidental eccentricity is used to calculate the value of accidental eccentricity. This value is typically 0.05 but may be increased to 0.10 for highly irregular buildings. This value can be positive or negative to accommodate clockwise or counter-clockwise rotation.

The response spectrum plot is generated as these parameters are specified.

5. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   **Note:** For the ASCE method, there are two optional parameters, FF1 and FF2, which can be checked and specified.

6. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec².

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an .acc file extension.

7. Select if the **Interpolation Type** is **Linear** or **Logarithmic**.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.

8. Select the **Damping Type** to use and, if explicit Damping is selected, type the damping ratio to be used for all modes.

9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).

10. (Optional) You can apply each of the following optional steps as needed:

    a. Select one of the **Signed Response Spectrum Results Options** if needed:

       check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

       or

       check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

    b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

       If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

    c. Type a **Scale** factor to apply to the spectra data.

    d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

    e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

       If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.

    The new response spectrum is added to the currently selected load case.

**Related Links**

- [TR.32.10.1.6 Response Spectrum Specification per IS: 1893 (Part 1)-2002](#) (on page 2721)
M. To add an IBC 2006 response spectrum

To specify a response spectrum for seismic loading per the IBC 2006 / ASCE 7-05 codes, use the following procedure.

1. Either:

On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group.

Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the Load & Definition dialog, select a primary load case in the Load Cases Details list and then click Add. The Add New Load Items dialog opens.

2. Select the Response Spectrum tab.

3. Select IBC 2006/ASCE 7-05 in the Code list.

4. Specify the IBC 2006 / ASCE 7-05 specific parameters:
   a. Specify the mapped acceleration values by either:
      - typing the Zip code (location and values are populated)
      - delete the Zip code value and type Latitude and Longitude (values are populated)
      - delete the Latitude value and type the Ss and S1 values directly
   b. Type the Long Period (TL) value for the structure.
   c. Type the Fa and Fv values for the soil conditions at the location.
   d. Select a Site class (SCL) for the location.

The response spectrum plot is generated as these parameters are specified.

5. Select the Combination Method to use to combine the responses from each mode into a total response.

6. (Optional) Check the Save option to create a file contain the joint accelerations in ratios of gravity and in radians/sec^2.

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an .acc file extension.

7. Select if the Interpolation Type is Linear or Logarithmic.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.

8. Select the Damping Type to use and, if explicit Damping is selected, type the damping ratio to be used for all modes.

9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).

10. (Optional) You can apply each of the following optional steps as needed:
a. Select one of the **Signed Response Spectrum Results Options** if needed:

check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

or

check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

c. Type a **Scale** factor to apply to the spectra data.

d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.

The new response spectrum is added to the currently selected load case.

**Related Links**

- [TR.32.10.1.8 Response Spectrum Specification per IBC 2006](on page 2743)

**M. To add an EC8 response spectrum**

Floor height is determined by the program as a joint where one or more beams frame in a column.

Eurocode 8 requires the use of cracked section stiffness when considering concrete buildings, which however is lacking in the current analysis engine. This can be overcome by using a section reduction factor as suggested in the code. STAAD.Pro has a "section reduction factor" that can be used for this purpose (i.e., the **MEMBER CRACKED** command). Refer to [TR.20.10 Member Property Reduction Factors](on page 2485) for details on this command.

**Note:** Refer to [TR.32.10.1.5 Response Spectrum Specification per Eurocode 8 2004](on page 2715) for additional information on using the response spectrum specifications per Eurocode 8.

1. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

**Tip:** This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Response Spectrum** tab.

3. Select **EURO (EC8) - 2004** in the **Code** list.
4. Specify the EC8-2004 specific parameters:
   a. In the Spectrum table group, type the **Design Ground Acc(eleration) factor**.
   b. Type the **Behaviour Factor**.
   c. Select the **Subsoil Class** from the drop-down list.
   d. In the **Load Type** group, select if the load is in the **Elastic** or **Design** range and then select if the load is **Type I** or **Type II**.

   The response spectrum plot is generated as these parameters are specified.

5. Select the **Combination Method** to use to combine the responses from each mode into a total response.

   **Note:** For the **ASCE** method, there are two optional parameters, **FF1** and **FF2**, which can be checked and specified.

6. (Optional) Check the **Save** option to create a file contain the joint accelerations in ratios of gravity and in radians/sec².

   The file name is saved in the same location as the STAAD input file, will have the same root filename as the STAAD input file but with an .acc file extension.

7. Select if the **Interpolation Type** is Linear or Logarithmic.

   The logarithmic option is recommended when only a few spectra data points are entered, as spectra vs period curves are typically only linear on a log-log scale.

8. Select the **Damping Type** to use and, if explicit Damping is selected, type the damping ratio to be used for all modes.

9. Select the directions which spectrum is applied and for each, type a factor (0-1.0).

10. (Optional) You can apply each of the following optional steps as needed:

    a. Select one of the **Signed Response Spectrum Results Options** if needed:

        check **Dominant** and type a **Mode No** to use for determine the signs of all modes. You can alternatively type 0 for the Mode No to have the program select the mode with the greatest percent participation in the excitation direction for the dominant mode.

        or

        check **Sign** to create signed values for all results by comparing the sum of the squares of positive versus negative results.

    b. To generate individual modal response load cases, check the **Generate load case(s) for first** option and then type the number of load cases to generate. You can also type the Load Case number to use for the first of the generated load cases.

        If the number of load cases requested is larger than the number of modes extracted, then only the number of modes extracted is used.

    c. Type a **Scale** factor to apply to the spectra data.

    d. Check the **Missing Mass** option to include the static effect of masses not represented in the modes. Type an optional spectral acceleration for this missing mass mode.

    e. If the Missing Mass option is used and you want to specify an acceleration corresponding to a frequency instead, check the **ZPA** option and type a frequency.

        If neither the missing mass acceleration value or ZPA frequency is specified, then the spectral acceleration at 33Hz is used to calculate the missing mass mode.

11. Click **Add**.

    The new response spectrum is added to the currently selected load case.
This response spectrum may be used with a linear, elastic analysis, geometric nonlinear analysis, or a pushover analysis for review of Eurocode 8 seismic requirements in the Earthquake workflow (on page 2240).

M. Snow Loads

This section describes how to add snow loads to your STAAD.Pro model.

M. To add an ASCE 7-02 snow load

Loads and definitions are added from the Load & Definition dialog in the Loading page.

Snow load definitions are applied to floor groups. You must have at least group of the type Floor previously defined.

Tip: You may want to change your input units to make entering snow loads convenient.

1. In the Load & Definition dialog, select the Definitions > Snow Definition entry and click then Add.
   The Add New: Snow Definition dialog opens.
2. Enter the general snow parameters and click the Add button.
   The newly created snow load definition will appear in the Definitions > Snow Definition section in the Load & Definition dialog.
3. Either:
   Repeat step 2 to add a second snow load definition.
   or
   Click Close to stop adding snow load definitions.
4. (Optional) Create a new primary load case for use with the snow load.
5. In the Load & Definition dialog, select the primary load case which will include the snow load.
6. Click Add.
   The Add New: Load Items dialog opens.
7. Select the Snow Load tab.

   Note: If no floor groups have been defined, this page will be inactive and a warning message is displayed in the dialog.
8. Select the Floor Group and select the Snow Load parameters.
9. Click Add.
   The snow load is added to the primary load case.

Related Links
• Add New Snow Definition dialog (on page 3043)
• TR.31.5 Definition of Snow Load (on page 2641)
• G.16.4 Snow Load (on page 2345)

• TR.32.13 Generation of Snow Loads (on page 2785)
M. Notional Loads

Notional loads are nominal lateral loads used in a direct analysis, such as specified in AISC 360.

M. To define direct analysis parameters

To define the member parameters used in an AISC 360 direct analysis, use the following procedure.

1. On the Loading ribbon tab, select the Direct Analysis tool in the Define Load Systems group.
   The Create New Load Items dialog open.
2. Specify the initial $\tau_b$ value:
   Members whose flexural stiffness are considered to contribute to the lateral stiffness of the structure will have their flexural stiffness (EI) reduced by $0.8 \times \tau_b$.
   a. Select the FLEX Parameter tab.
   b. Type a FLEX value.
   c. Click Add.
3. Specify the yield strength value:
   a. Select the FYLD Parameter tab.
   b. Type a FYLD value.
   c. Click Add.
4. (Optional) Identify any axial members which contribute to the lateral stiffness of the structure:
   a. Select the AXIAL Parameter tab.
   b. Click Add.
5. Click Close.
6. In the Load & Definition dialog, expand the Definitions > Direct Analysis Definition group.
7. Assign each of the FLEX, FYLD, and AXIAL parameters listed to the corresponding members in the model.

You must add one or more load cases with notional loads to your model for a direct analysis.

Related Links

- G.17.2.1.4 AISC 360 Direct Analysis (on page 2352)
- TR.31.7 Definition of Direct Analysis Members (on page 2643)
- Add New Direct Analysis Definition dialog (on page 3047)

M. To add a notional load case

To add notional loads to a load case for use with direct analysis, use the following procedure.

Notional loads are lateral loads which are defined as a small percentage of gravity loads. Therefore, you must define your gravity loads in a separate reference load case (recommended) or primary load case before adding notional loads.

The notional loads are calculated as lateral loads applied to the joints in the selected global direct.

1. Either:

   On the Loading ribbon tab, select the Load Items tool in the Loading Specifications group
Tip: This will add the load item to the currently selected load group selected in the program status bar.

or

In the Load & Definition dialog, select a primary load case in the Load Cases Details list and then click Add. The Add New Load Items dialog opens.

2. Select the Repeat Load > Notional Load tab.

Two load lists are displayed. The first is a list of primary load cases which occur before the current primary load case and the second is a list of reference load definitions.

3. Either:

   select a load case or reference load case on the right and click > to add it to the notional load
   or
   click either >> to add either all of the load cases or reference loads to the notional load

4. Type a Factor to use for the ratio of lateral to gravity loads for each load case added to the notional load.

   Typically, codes recommend 0.2 to 0.3 % (0.002 to 0.003). The default value will be the Notional Load Factor specified in the Direct Analysis Definition.

5. Select the global Direction for each load case added to the notional load.

6. Click Add.

M. Moving Loads

This section describes how to generate basic moving loads to your STAAD.Pro model.

Moving loads generated by the moving load generator in STAAD.Pro are only applied to beams. Plates and surfaces cannot be loaded using these loads.

For bridge decks which are skewed with respect to the global axes, the load generation may not yield the most satisfactory results. In such cases, the M. Bridge Deck workflow (on page 883) is recommended is recommended. The Bridge Deck workflow works on the influence line/influence surface method, and is considerably superior to the moving load generator. It also has the advantage of being able to calculate the critical load positions on decks modeled using plate elements.

Related Links

- TR.31.1 Definition of Moving Load System (on page 2541)
- V. Moving Load Generator (on page 3546)

M. To define a vehicle for loading

In order to generate a set of static loads, due to the movement of the vehicle or load on the structure, there are multiple steps involved.

Note: This procedure is used to generate a set of static loads at intervals on a structure. The Bridge Deck workflow (on page 883) can also be used to automatically place loads at locations to achieve maximum or minimum actions on a bridge deck.
1. Either:
   - on the **Loading** ribbon tab, select the **Moving Loads** tool in the **Loading** group

   or

   Select **Vehicle Definitions** under **Definitions** in the **Load & Definition** dialog and then click **Add**.
   The **Add New Vehicle Definition** dialog opens.

2. Specify a **Vehicle Type Ref** number.
   This identification number is used to refer to this vehicle load definition in the moving load generator.

3. Either:
   - define a custom vehicle using the **Define load** tab
   - select a standard AASHTO vehicle definition using the **AASHTO Spec** tab
   - select an external file containing vehicle data using the **File Input** tab

4. Click **Add**.

**Related Links**
- *G.16.1 Moving Load Generator* (on page 2343)
- *Add New Vehicle Definitions dialog* (on page 3048)
- *TR.31.1 Definition of Moving Load System* (on page 2541)

**M. To generate moving load cases**

To create a generation of load cases, use the following procedure.

1. In the **Load & Definition** dialog, select the **Load Case Details** entry and then click **Add**.
   The **Add New: Load Cases** dialog opens.
2. Select the **Load Generation** tab.
3. Type the **No. of Loads** to be generated.
   This is the total number of load positions that will be generated. You will later define the starting location and the increment distance between each position.
4. (Optional) Select the **Predefined Loads to be Added** from the drop-down list.
5. Click **Add**.

The moving load generation case is added to the **Load Case Details** entry in the **Load & Definition** dialog. These cases are marked with a [G] to indicate that they are generations of load cases. The load case number range is given in the title.

**Related Links**
- *G.16.1 Moving Load Generator* (on page 2343)
- *Load Generation dialog* (on page 3031)
- *TR.32.12.1 Generation of Moving Loads* (on page 2771)
M. To add vehicles to the load generation

To add a vehicle definition to the moving load generation, use the following procedure.

1. Select a moving load generation case in the Load Case Details entry in the Load & Definition dialog and then click Add.
   The Add New: Load Cases dialog opens.
2. Select the vehicle definition in the Type drop-down list.
3. Type the coordinates for the Initial Position of the Load.
   This is where the reference load (i.e., the first specified concentrated load in the moving load system) is placed on the structure for the first load case in the generation.
4. Type the Load Increment values in the planar directions to move the load for each subsequent load case.
5. Click Add.
6. (Optional) Repeat steps 2 through 5 to add additional moving loads to the load generation case.
7. Click Close.

M. Time History Loads

This section describes how to add time history loads to your STAAD.Pro model.

M. To define a time history type from tabular data

To use a set of time value pairs to define a time history load, use the following procedure.

1. On the Loading ribbon tab, select the Time History > Forcing Function tool in the Dynamic Specifications group.

   The Add New: Time History Definitions dialog opens.
2. Type an Integration Time Step value in seconds.
3. (Optional) Select the Consider Missing Mass Mode option if necessary.
4. (Optional) Select the Save option to generate a file with time history data.
5. Select the Loading Type for your data:
   Acceleration
   or
   Force
   or
   Moment
6. Type the **Define Time vs** load data values in the table. As you add data pairs, the chart below is populated.

7. Click **Add**.

**Note:** You must define time history parameters to complete the time history load definition.

**Related Links**
- *G.17.3.5 Response Time History* (on page 2373)
- *TR.31.4 Definition of Time History Load* (on page 2630)
- *Add New Time History Definitions dialog* (on page 3056)

**M. To define a time history type from a function**

To use a parametric function to define a time history load, use the following procedure.

1. On the **Loading** ribbon tab, select the **Time History > Forcing Function** tool in the **Dynamic Specifications** group.

   The **Add New: Time History Definitions** dialog opens.

2. Type an **Integration Time Step** value in seconds.
3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.
4. (Optional) Select the **Save** option to generate a file with time history data.
5. Select the **Loading Type** for your data:
   - Acceleration
   - Force
   - Moment

6. Select the **Harmonic Function** option in the Function Options group.
7. Select the harmonic function to use: **SINE** or **COSINE**.
8. Select one of the options for specifying wave length:
   - select **Frequency** and enter a cyclic frequency in cycles/sec.
   - select **RPM** and enter the revolutions per minute
9. Specify the harmonic wave parameters:
   - **a.** Enter the **Amplitude** in the units indicated.
     These correspond to the current input units and the **Loading Type** selection.
   - **b.** (Optional) Enter the **Phase** angle in degrees.
   - **c.** Enter the number of **Cycles** of loading.
10. Specify the number of time steps per cycle by either:
    - select the **Step** option and enter the time step of the loading.
or

select the SubDiv option and enter a number of subdivisions per quarter cycle (i.e., from zero to peak amplitude along the sine or cosine wave).

11. Click Add.

**Note:** You must define time history parameters to complete the time history load definition.

**Related Links**
- G.17.3.5 Response Time History (on page 2373)
- TR.31.4 Definition of Time History Load (on page 2630)
- Add New Time History Definitions dialog (on page 3056)

### M. To define a time history type by spectrum

To define a time history type using spectral parameters, use the following procedure.

1. On the **Loading** ribbon tab, select the **Time History** > **Forcing Function** tool in the **Dynamic Specifications** group.

   The **Add New: Time History Definitions** dialog opens.

2. Type an **Integration Time Step** value in seconds.

3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.

4. (Optional) Select the **Save** option to generate a file with time history data.

5. Select the **Loading Type** for your data:
   - Acceleration
   - Force
   - Moment

6. Select the **Spectrum** option in the Function Options group.

7. Specify the time data:
   a. Enter the maximum time (in seconds) in the generated time history in the **Tmax** field.
   b. Enter the time step (in seconds) in the **DeltaT** field.
   c. Enter the time at the end of rising acceleration in the **T1** field.
   d. Enter the time at the end of the steady acceleration in the **T2** field.
   e. Enter the time at the end of the acceleration decay in the **T3** field.

8. Enter the damping ratio in the **Damp** field.

9. Specify the options:
   a. (Optional) Type a **Random Seed** value.

   Enter a positive integer (1 to 2147483647) to be used as a unique random number generation "seed." A unique time history will be produced for each seed value. Change this value when you want to produce a
“different (from the time history generated with the prior seed value)” but statistically equivalent time history.

b. Enter the No of digitized Freq.  
   This is the number of equally spaced frequencies at which the input shock spectrum is re-digitized (by interpolation).

c. Enter the No. of Iteration which will be used to perfect the computed time history.

10. Click Add.

For response spectra time history, there are some additional output parameters that must be input via the STAAD.Pro Editor if used.

**Note:** You must define time history parameters to complete the time history load definition.

**Related Links**
- [G.17.3.5 Response Time History](#)
- [TR.31.4 Definition of Time History Load](#)
- [Add New Time History Definitions dialog](#)

### M. To generate output for time history spectrum

To generate some additional output data for spectrum input for a time history definition, use the following procedure.

Create a structure with a time history definition using the Spectrum option.

These optional commands cannot be entered via the graphical user interface. They are required to be added using the STAAD.Pro Editor.

1. On the **Utilities** ribbon tab, select the **Command File Editor** tool in the **Utilities** group.

   The STAAD.Pro Editor window opens with the current STAAD input file.

2. (Optional) To output time history data: after the DEFINE TIME HISTORY command, in the SPECTRUM options, add the command THPRINT $f_{18}$.

   Where $f_{18}$ directs the program to output either the beginning and last 54 data points ($f_{18} = 1$) or the entire curve ($f_{18} = 2$) or a select number of beginning and last data points ($f_{18} \geq 10$).

   The spectrum input parameters will be included in the STAAD Output (.anl) file along with the Time History Output (limited to the $f_{18}$ value specified).

3. (Optional) To generate spectrum output for a time history: after the DEFINE TIME HISTORY command, in the SPECTRUM options, add the command SPRINT $f_{19}$.

   Where $f_{19}$ represents an integer value after the SPRINT command to instruct the program to only output the beginning and last number of values equal to this integer.

   A summary of the Spectrum input and the curve points will be included in the STAAD Output (.anl) file.

4. Save the command input file and then exit the STAAD.Pro Editor.

**Related Links**
- [TR.31.4 Definition of Time History Load](#)
M. To use frequency-spectra pairs in a time history load

To instruct the program to use frequency-spectra pairs in lieu of period-spectra pairs for the time history spectrum input, use the following procedure.

Create a structure with a time history definition using the Spectrum option.

These optional commands cannot be entered via the graphical user interface. They are required to be added using the STAAD.Pro Editor.

1. On the **Utilities** ribbon tab, select the **Command File Editor** tool in the **Utilities** group.

   ![Command File Editor](image)

   The STAAD.Pro Editor window opens with the current STAAD input file.

2. After the `DEFINE TIME HISTORY` command, in the `SPECTRUM` options, add the command `FREQ`.

3. Save the command input file and then exit the STAAD.Pro Editor.

**Related Links**

- *TR.31.4 Definition of Time History Load* (on page 2630)

M. To define a time history type by external file

To define a time history type using data in an external text file, use the following procedure.

You must have a separate text file containing pairs of times and values (acceleration, force, or moment). The file extension is not important, but the values must be in plain text.

1. On the **Loading** ribbon tab, select the **Time History > Forcing Function** tool in the **Dynamic Specifications** group.

   ![Time History Forcing Function](image)

   The **Add New: Time History Definitions** dialog opens.

2. Type an **Integration Time Step** value in seconds.

3. (Optional) Select the **Consider Missing Mass Mode** option if necessary.

4. (Optional) Select the **Save** option to generate a file with time history data.

5. Select the **Loading Type** for your data:

   - Acceleration
   - Force
   - Moment

6. Select the **From External File** option in the Function Options group.

7. Type the **File Name** (with or without file extension).

8. Click **Add**.
An example of an external data file:

<table>
<thead>
<tr>
<th>0.0</th>
<th>1.0</th>
<th>1.0</th>
<th>1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0</td>
<td>1.8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3.0</td>
<td>2.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4.0</td>
<td>2.6</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If you need to specify a delta time spacing used for the external file data, this must be done using the STAAD.Pro Editor.

**Note:** You must define time history parameters to complete the time history load definition.

### Related Links
- [G.17.3.5 Response Time History](#) (on page 2373)
- [TR.31.4 Definition of Time History Load](#) (on page 2630)
- [Add New Time History Definitions dialog](#) (on page 3056)

### M. To define time history parameters

To define arrival times and damping used for time history loads, use the following procedure.

You must first define a time history type by one of the previously described methods.

One set of time history parameters can be defined for your model for all time history load types.

1. On the **Loading ribbon** tab, select the **Time History > Parameters** tool in the **Dynamic Specifications** group.

   The **Define Param** dialog opens.

2. **(Optional) Check the Time Step option and type the time step value.**
   
   This is the solution time step used in step-by-step integration of the uncoupled equations. If not selected, the default value of 0.0013888 seconds is used.

3. Select the **Damping Type** to use and, if explicit **Damping** is selected, type the damping ratio to be used for all modes.

4. **Type in one or more Arrival Times for the dynamic loads.**
   
   Arrival time is the time at which a load type begins to act at a joint (forcing function) or at the base of the structure (ground motion).

5. **Click Add.**

The time history load parameters are added to the **Time History Definitions** in the **Load & Definition** dialog.

In order to use a time history load definition, you must add a time history load item to a primary load case.

### Related Links
- [G.17.3.5 Response Time History](#) (on page 2373)
- [Define (Time History) Parameters dialog](#) (on page 3058)
- [TR.31.4 Definition of Time History Load](#) (on page 2630)
M. To add a time history load

To add a time history load to the current primary load case, use the following procedure.

Select the current load case in the program status bar.

1. Either:
   - On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.
     
     **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   - or
     - In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

2. Select the **Time History** tab.
3. Select the **Load Type**:
   - **Time Load** for a forcing function that applies forces or moments to joints
   - or
   - **Ground Motion** is applied global to all supports as an acceleration type
4. Select Direction in which the load is applied.
   - Time Load types are applied in FX, FY, or FZ for forces and MX, MY, or MZ for moments. Ground motion types are applied in one of the three global directions.
5. Select the arrival time for this load from the arrival times in the time history definition parameters.
6. Select the load definition type from the Defined Types drop-down list.
   - The list includes the definition number and function type.
7. (Optional) Select the results type from the Response Types drop-down list.
8. (Optional) Type a Force Amplitude Factor to multiply for the forces, moments, or accelerations at the joints.
9. Click **Add**.

You must assign the time history load to the joints to which it applies.

M. Pushover Loads

This section details create a pushover loads for use with a pushover analysis in STAAD.Pro.

**Note:** An advanced analysis module license is required to use a pushover analysis.

**Related Links**
- **Perform Pushover Analysis tab** (on page 3075)
- **A. To specify a pushover analysis** (on page 933)
M. To define general pushover data

1. On the Loading ribbon tab, select the Pushover tool in the Define Loading Systems group. The Create New Definitions / Load Cases / Load Items dialog opens with only the Pushover tab displayed.
2. On the Define Input tab (on page 3049), select the General Input Parameters option.
3. (Optional) Select the Type of Frame
4. (Optional) Select Include Effect Geometric Non-Linearity Effect

Related Links
- Define Input tab (on page 3049)

- TR.37.7.7 End Pushover Data (on page 2828)

M. To define member specific pushover data

Use the following optional procedure to specify parameters for individual members.

1. On the Loading ribbon tab, select the Pushover tool in the Define Loading Systems group. The Create New Definitions / Load Cases / Load Items dialog opens with only the Pushover tab displayed.
2. On the Define Input tab, select the Member Specific Parameters option.
3. (Optional) Set the Expected Yield Stress
4. (Optional) Set the Effective Length Factor for Member (Y/Z)
5. Click Add.
6. Once any other parameters have been added, click Close. Entries for the member parameters are added in the Loads & Definitions dialog in the Definitions > Pushover Definitions section.
7. Select one of the member parameters and click Assign.

Note: Refer to Graphical Environment help for using the various assignment methods in the Loads & Definitions dialog.

Related Links
- Define Input tab (on page 3049)
- TR.37.7.2.2 Expected Yield Stress (on page 2819)
M. To manually define and assign hinges

Use the following optional procedure to define parameters and assign hinges manually.

**Note:** If the pushover analysis will make use of the built-in FEMA hinge properties for all members,

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group. The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. Select the **Define Hinge Property** tab.
3. Select the **Hinge Type**.
   Types **FEMA** or **Ignore** do not require any additional parameters.
4. (Optional) For user-defined hinge types only:
   a. Select an existing **Type ID** or select **New Type** to define a new hinge type.
   b. Specify a unique integer for the **Type Identifier**.
   c. Specify coordinate values for points C, D, and E in the **Load Deformation Curve Points** and IO, LS, and CP values in the **Acceptance Criteria**.
      These values are can be determined using Tables 5-6 and 5-7 in FEMA 356.
   d. Specify values for **Yield Moment (YR)** and **Yield Rotation (YR)**.
      These values are calculated per Section 5.5.2.2.2 of FEMA 365 ([See “Frame element hinge properties”](on page 2382)).
5. Click **Add**.
6. Once any other parameters have been added, click **Close**.
   Entries for the hinge types are added in the **Loads & Definitions** dialog in the **Definitions > Pushover Definitions** section.
7. Select one of the hinge types and click **Assign**.

**Note:** Refer to Graphical Environment help for using the various assignment methods in the Loads & Definitions dialog.

**Related Links**

- **Define Hinge Property tab** (on page 3053)

M. To define pushover spectral data

Use the following procedure to define the seismic hazard per FEMA 356.

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group. The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. Select the **Define Spectral Details** tab.
3. Specify up to four **Critical Damping** values for the 1st through 4th spectra. At least one is required, which has a default value of 5.0%.
4. (Optional) Select the **Site Category**
   Site Class D is used by default.
5. Specify the Mapped Spectral Acceleration **At Short Period**, $S_s$, to be used per Table 1-4 of FEMA 356.
6. Specify the Mapped Spectral Acceleration **At One-Second Period**, $S_1$, to be used per Table 1-5 of FEMA 356.
7. Click **Add**.

**Related Links**

M. To add a pushover loading

Use the following procedure to define the pushover loading to be used in the pushover analysis.

1. On the **Loading** ribbon tab, select the **Pushover** tool in the **Define Loading Systems** group. The **Create New Definitions / Load Cases / Load Items** dialog opens with only the Pushover tab displayed.
2. Select the **Define Loading Pattern** tab.
3. (Optional) Select **User Defined**
   If the default Auto load pattern is used, the program will internally compute the gravity loads.
4. (Optional) Set the **Method for Lateral Load Calculation**
   See "Program Defined Push Load Distribution Pattern" (on page 2823) for additional information on each method.
5. (Optional) Set the **Total Base Shear to be Distributed Direction Total Base Shear**
6. (Optional) Specify a **Number of Push Load Steps**
7. Click **Add**.

**Tip:** Only one pushover loading definition may be used for a model. If a different pushover loading definition is required, either change the individual parameters or delete them and create a new definition.

**Related Links**

- [Define Loading Pattern tab](on page 3051)
M. To define solution control

Use the following procedure to define at least one solution control method for the pushover analysis.

1. On the Loading ribbon tab, select the Pushover tool in the Define Loading Systems group. The Create New Definitions / Load Cases / Load Items dialog opens with only the Pushover tab displayed.
2. Select the Define Solution Control tab.
3. (Optional) Set the Push Up to Defined Base Shear Direction Defined Base Shear
4. (Optional) Set the Push Up to Defined Displacement at Control Joint Direction Joint Displacement Value Joint Number
5. Click Add.

Related Links
- G.17.4.2.1.6 Define Pushover Analysis Solution Control (on page 2390)
- TR.37.7.4 Define Solution Control (on page 2825)
- Define Solution Control tab (on page 3055)

M. To use starting vectors with load-dependant Ritz vectors

You must set the eigen method to use load-dependant Ritz (LDR) vectors in order to specify the starting vectors for that method. On the Analysis and Design ribbon tab, select the Miscellaneous Commands > Set Eigen Method tool in the Analysis Data group. Then select the Load Dependant Ritz Vectors (LDR) option and click OK.

Note: This method is used to specify starting mass loads only. In order to specify starting load from reference load cases, you must directly edit the STAAD input file.

1. Select the Loading page in the Analytical Model workflow.
2. Select Starting Load Definition under Definitions in the Load & Definition dialog and then click Add. The Add New Define Starting Mass Load dialog opens.
3. Select the directions you want to use for the starting mass load vectors.
4. (Optional) For each direction selected, enter the number of vectors to be extracted corresponding to that load.
5. Click OK.

Related Links
- TR.31.9 Defining Starting Load (on page 2648)

- TR.31.9 Defining Starting Load (on page 2648)

M. Load Combinations

This section describes how to add load combinations to your STAAD.Pro results.
Note: Load combinations of primary load cases are algebraic combination of analysis results. Therefore, they are not applicable to nonlinear analyses.

Load Combinations with Loads from STAAD.Pro Physical Modeler

When you are creating load combinations using loads from STAAD.Pro Physical Modeler, there are two approaches:

1. Creating primary loads for each reference load generated from STAAD.Pro Physical Modeler. This will combine the analysis results of primary load cases and allow you to include the STAAD.Pro Physical Modeler loads in those results.
2. Using repeat load combinations. These load combinations will use the reference load cases generated by STAAD.Pro Physical Modeler (with any necessary load factors).

Note: Do not use primary load cases with STAAD.Pro Physical Modeler reference loads and repeat style load combinations, or the results of those load cases will be included twice.

M. To define a new load combination

To manually define a load combination for post-processing, use the following procedure.

One or more primary load cases or load combinations must be defined in order to create a combination.

Note: Load combinations are not directly processed by the analysis engine. Instead, their results are combined as specified by the combination method. In order to process combinations of load cases use either a Repeat Load or a Reference Load in a new Primary Load case.

1. On the Loading ribbon tab, select the Combinations tool in the Loading group.

   The Define Load Combinations dialog opens.

2. Type the Load No and load combination Name.

3. Select the combination Type to use:
   - Normal - a linear combination of a factor multiplied by a load result value
   - SRSS - a linear combination of either a Normal type or a square root of the sums squared (SRSS) combination. The factors for each control how each load component is added to the resulting combination
   - ABS - a linear combination of a factor multiplied by the absolute value of a load result

4. Select a Primary load case or existing load combination from the Available Load Cases list and then click > to add the load combination definition.

   The selected load case is added with the default type factors defined above. You can change the factors for an individual load combination component as needed.

Moving Loads: In order to include the individual load cases from a moving load generator, you must add these using the STAAD.Pro Editor. They cannot be entered using the dialog as they are not generated until the STAAD engine processes the input file.

5. Repeat step 4 for all load components to be added to this load combination.
Tip: Click >> to include all Available Load Cases, which will be use the default factors.

6. (Optional) To remove a load component from the Load Combination Definition, select the component in and then click <. To remove all load components, click <<.

7. Click Add.

Related Links
• TR.35 Load Combination Specification (on page 2791)
• Define Load Combinations dialog (on page 3003)

M. To define primary load type

To define or change the load type specified for a primary load case, use the following procedure.

You can define or change the load type for any previously added primary load case.

The load type is used for automatic load combinations.

1. On the Loading ribbon tab, select the Primary Load Type tool in the Load Generation group.

2. For each primary load case, select the Type from the drop-down list in the cell.

3. (Optional) For Life or Roof Life load types, check the Reducible-IBC 2003 if this particular load is considered a reducible live load per IBC.

4. Repeat steps 2 and 3 for all primary load cases.

5. Click OK.

Related Links
• Define Load Type dialog (on page 3032)
• TR.32 Loading Specifications (on page 2650)

M. To define automatic load combination rules

To define new or to edit existing rules for generating automatic load combinations, use the following procedure.

Note: In order to properly generate load combinations for Eurocode (unofficially referred to as EC0), the program contains a macro which allows for gamma inputs. For that code, refer to “M. To generate load combinations per Eurocode (on page 870).”

1. On the Loading ribbon tab, select the Automatic Combinations > Edit Auto Combination Rules tool in the Load Generation group.

The Edit Loading Rules for Auto Load Combination Generation dialog opens.

2. (Optional) To create a new Code and Category of load combinations:
a. Click **New Code**. The *Add New Code* dialog opens.

![Add New Code](image)

b. Type a **Code Name** and then click **OK**. A new, empty table is loaded.

c. Click **New Category**. The *Add New Category* dialog opens.

![Add New Category](image)

d. Type the **Category Name** and the **No. of Rules** to initially create in the table. You can add or remove table rows after you create the table.

e. Click **OK**. The specified rows are added for the new table.

3. For each load type (i.e., column):

    a. Set the **Include Notional Loads?** check box to include notional loads in this type for direct analysis. Notional loads are included by default only in dead, live, roof life, snow, and ice load types.

    b. Select the appropriate **Combination Rule** option for this load type:

        • **Combine all cases together** - For each rule, a single combination will be created which will include all the load cases of that load category multiplied by the factor in the table.

        • **Separate combination for each case** - For each rule, multiple combinations will be created, each will include one of the load cases of that load category multiplied by the factor in the table.

        • **All possible combinations** - For each rule, multiple combinations will be created which will include each of the load cases of that load category on their own and with each and every other load case of that category multiplied by the factor in the table.

4. For each combination (i.e., row) in the table, specify the load multiplier for the load types present in that load combination.

**Tip:** To add a new road, click **Add Row**. To remove a row, click the row number to highlight the entire row and then press `<Delete>`.
5. To save the changes to a table, click **Update Table**.
6. Repeat steps 3, 4, and 5 individually as needed to specify the load combinations for the code category.
7. Click **Close**.

You can now generate load combinations using this rule set.

**Related Links**
- [Edit Load Rules for Auto Load Combination Generator dialog](#)
- [Edit Load Rules for Auto Load Combination Generator dialog](#)

M. To automatically generate load combinations

To automatically generate load combinations based on predefined rules for load types, use the following procedure.

In order to use this feature, one or more primary load cases must be created with a load type defined. A load type can be assigned to a primary load case either at the time when the load is being created or later.

If you want to customize the load combination rules or create your own for your organization, you must do this before creating the automatic load combinations.

**Note:** In order to properly generate load combinations for Eurocode (unofficially referred to as EC0), the program contains a macro which allows for gamma inputs. For that code, refer to “M. To generate load combinations per Eurocode” (on page 870).

1. On the **Loading** ribbon tab, select the **Automatic Combinations** > **Automatic Load Combinations** tool in the **Load Generation** group.

   The **Auto Load Combination** dialog opens.

   **Note:** If no load cases have yet been defined for the model, a warning message is displayed over the dialog and the parameters are inactive. Primary load cases are defined using the **Create Primary Load Case** dialog.

2. Choose the code to use from the **Select Load Combination Code** drop-down list.
3. Chose the code-specific load combination table to use from the **Select Load Combination Category** drop-down list.
4. (Optional) Type the **Select Starting Combination No** to use for the first generated load combination.
5. (Optional) Check the **Create Repeat Load Cases** option to generate repeat load cases in place of results load combinations.
   Standard load combinations are algebraic combinations of results and therefore are not appropriate for second order effects. A repeat load case is a new primary load case which will re-use the loads from previously defined primary load cases in the analysis engine.
6. (Optional) Check the **Include Notional Load?** option to include notional loads (when notional loads have been specified) in the Repeat Load Cases.
7. Click **Generate Loads**.
   The load combinations based on the selected code and category are displayed in the **Selected Load Combinations** list.
8. Select any loads you do not want included in the load combinations and then click < to place them in the **Discarded Load Combinations** list.
9. Click Add.

Related Links
• Auto Load Combination dialog (on page 3033)
• TR.35 Load Combination Specification (on page 2791)

M. To generate load combinations per Eurocode

To generate load combinations for the Strength limit state per Eurocode - Basis of structural design, BS EN 1990:2002+A1:2005 (sometimes referred to as “Eurocode 0”).

The load combination generator is capable of creating load combinations per equations 6.10, 6.10a, or 6.10b found in Cl. 6.4.3.2.

These equations specify the following combinations of loads:

\[ \sum_{j \geq 1} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,1} Q_{k,1} + \sum_{i > 1} \gamma_{Q,1} \psi_{0,1} Q_{k,1} \]

Alternatively, for the strength limit state, the less favorable of equations 6.10a and 6.10b may be used:

\[ \sum_{j \geq 1} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,1} \psi_{0,1} Q_{k,1} + \sum_{i > 1} \gamma_{Q,1} \psi_{0,1} Q_{k,1} \]

(6.10a)

\[ \sum_{j \geq 1} \xi_{j} \gamma_{G,j} G_{k,j} + \gamma_p P + \gamma_{Q,1} Q_{k,1} + \sum_{i > 1} \gamma_{Q,1} \psi_{0,1} Q_{k,1} \]

(6.10b)

where

\[ G_k = \text{Permanent actions} \]

\[ P = \text{Prestress actions} \]

\[ Q_k = \text{Variable actions} \]

Note: The effects in each of the above equations are always additive. If any effect is negative (that is, would reduce the final sum), its effect is taken as zero.

1. On the Utilities ribbon tab, select the User Tools > Euro Code Load Combination Generator tool in the User Tools group.

The Eurocode Combination Generator dialog opens.
2. Select the **Equation Number** to use for the generation of load combinations.

3. (Optional) Specify a **Start Combination Number**.

4. Select the **Method** as either:
   - **Combination** to use post-analysis combination of results, which appropriate for linear elastic analysis
   - **Repeat Load** to generate repeat load cases from the primary load cases, which is appropriate for second order effects and dynamic analysis

5. (Optional) Specify load Factors for use in the combination equations.

<table>
<thead>
<tr>
<th>Factor title</th>
<th>Equation notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permanent Actions, Gamma G</td>
<td>( \gamma_G )</td>
</tr>
<tr>
<td>Pre Stress Actions, Gamma P</td>
<td>( \gamma_P )</td>
</tr>
<tr>
<td>Variable Actions, Gamma Q</td>
<td>( \gamma_Q )</td>
</tr>
<tr>
<td>Permanent Action Reduction Factor, ( \bar{X} )</td>
<td>( \xi )</td>
</tr>
</tbody>
</table>
### Factor title | Equation notation
---|---
Variable Action Combination Factor, Psi 0 | $\psi_0$

**Note:** The default values are taken from those provided in EC0.

6. **(Optional)** Click Table A1.1 to select one of the recommended values for the Permanent Action Reduction Factor, Psi ($\psi_0$).

7. Click **Categories** to specify in which load action classification each STAAD.Pro load category is to be assigned.

<table>
<thead>
<tr>
<th>Action</th>
<th>Included Loads</th>
</tr>
</thead>
<tbody>
<tr>
<td>(None)</td>
<td>Loads of this type will not be included in generated load combinations.</td>

</tr>
<tr>
<td></td>
<td><strong>Tip:</strong> You may also want to include Mass or Gravity load.</td>
</tr>
<tr>
<td>Variable</td>
<td>Q (variable) By default, Live, Roof Live, Wind, and Snow are included.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip:</strong> You may also want to include loads such as Seismic, Temperature, etc.</td>
</tr>
<tr>
<td>Pre Stress</td>
<td>P (prestress) No loads are included by default in this category.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip:</strong> As STAAD.Pro does not use a load category for prestressing forces, a less-common load category such as Imperfection can be used for this action.</td>
</tr>
</tbody>
</table>

8. Click **Generate Combinations**.
A confirmation dialog box opens with the status of the export. Load cases are generated with the selection equation and load case number in the title.

**M. To add a repeat load case**

To create a primary load case using combinations of previously defined primary load cases, use the following procedure.

A repeat load case is treated as a new primary load. That is, it is processed by the analysis engine rather than being a combination of results. It is therefore applicable for P-Delta analysis.

A repeat load is added similar to a load item within a primary load case.

1. **Either:**

   On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group

   **Tip:** This will add the load item to the currently selected load group selected in the program status bar.
   
   or

   In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**.
The Add New Load Items dialog opens.

2. Select the Repeat Load tab.
   A list of the primary load cases which occur before the current primary load case is displayed.

3. Either:
   - select a load case on the left and then click \( > \) to add it to the repeat load definition
   - or
   - click \( >> \) to add all the primary load cases to the repeat load definition

4. (Optional) Type a load Factor to use for each primary load case included in the repeat load definition.

   **Note:** The primary load case data is factored rather than results.

5. Click Add.

6. Click Close.

**Related Links**
- TR.32.11 Repeat Load Specification (on page 2770)
- Repeat Load tab (on page 3028)

### M. To create a reference load

To define a reference load and add it to a reference load item, use the following procedure.

A reference load case allows you to construct a load case with load items but it will not be directly solved by the analysis engine. It is only solved when it is called by another load case. This allows you to limit the number of load cases analyzed.

**Tip:** A reference load of type Mass is especially useful to define the structure masses used for dynamic analyses. One reference load case can be used by each of those analysis commands.

1. In the Load & Definition dialog, select the Definitions > Reference Load Definitions entry and then click Add.
   The Add New Reference Load Definitions dialog opens.

2. (Optional) Type a Number for the load case.
   The program will increment the load case number based on existing load case numbers.

3. (Optional) Select the Loading Type.
   This selection is used when automatically generating load combinations. If you select a live load type, you may also indicated if the load is Reducible per UBC/IBC.

4. Type a Title used to easily identify this load case.

5. Click Add.
   The reference load definition is added to the Definitions > Reference Load Definitions entry in the Load & Definition dialog.

6. Add load items to the reference load definition.
   This is done similar to how you would add load items to a primary load case. Reference load definitions can contain:
   - selfweight loads
   - nodal loads
   - member loads
7. Either:

On the **Loading** ribbon tab, select the **Load Items** tool in the **Loading Specifications** group.

**Tip:** This will add the load item to the currently selected load group selected in the program status bar.

or

In the **Load & Definition** dialog, select a primary load case in the **Load Cases Details** list and then click **Add**. The **Add New Load Items** dialog opens.

8. Select the **Repeat Load > Reference Load** tab.

A list of the reference load definitions is in the **Available Load Cases** list.

9. Either:

select a reference load definition and then click > to add it to the Reference Load item

or

click >> to add all the available reference load definition to the Reference Load item.

10. Repeat Step 9 to add additional reference load definitions to the Reference Load item.

11. (Optional) Type a Factor to apply to each reference load definition in the Reference Load item as needed.

12. Click **Add**.

**Related Links**
- **Repeat Load tab** (on page 3028)
- **TR.31.6 Defining Reference Load Types** (on page 2642)

### M. Damping Modeling

In STAAD.Pro, you can specify damping for the entire structure, composite damping for each material in the structure, or damping for each mode. Modal damping can be explicitly defined for each mode or calculated by the program based on the first two frequencies.

#### M. To assign a composite damping ratio

To assign a damping ratio to a model selection, use the following procedure.

This method assigns a composite damping ratio by a material constant.

**Note:** If you assign a material definition (on page 792) to members, elements, or solids, then the critical damping ratio for that material will be used.

1. On the **Specifications** ribbon tab, select the **Constants > Damping Ratio** tool in the **Materials** group.
The **Material Constant - Damping Ratio** dialog opens.

2. Select either:

   - the **Enter Value** option and then type the composite damping ratio value (must be between 0.001 and 0.99)
   - or

   one of the three predefined materials: **Aluminum**, **Concrete**, or **Steel**

<table>
<thead>
<tr>
<th>Material name</th>
<th>Composite damping ratio value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aluminum</td>
<td>0.03</td>
</tr>
<tr>
<td>Concrete</td>
<td>0.05</td>
</tr>
<tr>
<td>Steel</td>
<td>0.03</td>
</tr>
</tbody>
</table>

3. Select the **To Selection** option to limit the assignment to the selection set.

4. Click **OK**.

**Related Links**
- [G.17.3.3.1 Composite Damping](#)
- [Material Constant dialog](#)
- [TR.26.2 Specifying Constants for Members and Elements](#)

**M. To explicitly define damping values for modes**

To define damping values for modes for use with dynamic analysis, use the following procedure.

1. On the **Loading** ribbon tab, select the **Modal Damping** tool in the **Dynamic Specifications** group.

   The **Modal Damping** dialog opens.

2. Select the **Explicit** option.

3. Type a **Damping** ratio to use for each mode number.

4. Click **OK**.

**Related Links**
- [G.17.3.3.2 Modal Damping](#)
- [Modal Damping dialog](#)
- [TR.26.4 Modal Damping Information](#)

**M. To evaluate damping for modes**

To instruct the program to evaluate the modal damping values from the first two...
STAAD.Pro also has a similar method available for calculating the modal damping when provided the mass-proportional damping coefficient, \( \alpha \) and the stiffness-proportional damping coefficient, \( \beta \). This method must be input using the STAAD.Pro Editor.

1. On the **Loading** ribbon tab, select the **Modal Damping** tool in the **Dynamic Specifications** group.

   ![Modal Damping dialog](image)

   The **Modal Damping** dialog opens.

2. Select the **Evaluate** option.

3. Type **Min** and **Max** values to evaluate damping values for each mode.

   The minimum damping value is used for the first two modes. This is also used to evaluate the damping coefficients for subsequent modes based on the first two modal frequencies. If any evaluated damping is greater than the specified maximum value, then the maximum damping is used instead. Refer to **Evaluate Damping** (on page 2370) for additional details.

4. Click **OK**.

### M. Mass Modeling

#### M. To add a mass model reference load

A mass model reference load is added in the same way as any other reference load, but with the Loading Type set to Mass.

1. Either:

   - on the **Loading** ribbon tab, select the **Reference Load Case** tool in the **Loading Specifications** group

   ![Reference Load Case tool](image)

   or

   - select the **Definitions > Reference Load Definitions** section of the **Load & Definition** dialog box and then click **Add**.

   ![Add reference load definition](image)

   or

   - (Optional) Type a reference load identification number in the Number field.
Tip: This number is incremented by one from any previously defined reference loads and typically does not need to be changed.

3. Select Mass as the Loading Type.
4. (Optional) Type a label in the Title
   For example, you may want to label the reference by typing Mass Model.
5. Click Add.
   The dialog box closes and a new reference load definition is added to the input file.

Related Links
• TR.31.6 Defining Reference Load Types (on page 2642)

M. To add mass loads to the mass model reference load

1. Select the mass Reference Load Case in the Load & Definition dialog box.
2. Click Add.
   The Add New: Reference Load Items dialog box opens.
3. Select the type of load you want to add from the tree.
4. Specify load parameters (e.g., magnitude, direction, etc.).
5. Click Add.
6. (Optional) Repeat steps 3 through 5 to add additional loads.
7. Click Close.

Related Links
• TR.31.6 Defining Reference Load Types (on page 2642)

M. To create a load envelope

To create a load envelope for grouping loads together in the analytical workflow, use the following procedure.

1. Select the Load Envelopes list on the Load & Definition dialog and then click Add.
   The Add New Load Envelopes dialog opens.
2. (Optional) Select an envelope Type from the drop-down list.

   Note: In the case of designing steel members for strength and serviceability, it is important to select the applicable load type.

3. Either:
   select a load case or load combination in the Available list and then click > to add that item to the envelope
   or
   click >> to add all the Available load cases and load combinations to the envelope
4. Repeat step 3 to add additional load cases or combinations to the envelope.
5. Click Add.
   The load envelope is added to the input file.
6. Repeat steps 2 through 5 to create additional load envelopes.
7. Click Close.

The STAAD.Pro Piping workflow is used to import piping support geometry and reactions from Bentley AutoPIPE.

The piping system in a plant model is supported by a number of structural components – such as pipe racks, cradles or shoes – constructed exclusively for that purpose or from the existing beams, columns and slabs of the structure. To facilitate the design of structures to sustain the loading imparted by the piping system, STAAD.Pro includes a seamless transfer of support reactions calculated from an AutoPIPE analysis to the structure modeled in STAAD.Pro.

**M. Using the Piping Workflow**

**General Workflow**

1. Import a piping model via the PipeLink utility.
2. Use the Support Connection Wizard to automatically assign connections between pipe nodes and structural entities.
3. Modify or add connections as necessary either graphically or via the Pipe Support table.
4. Transfer loads from the pipe stress model to the STAAD.Pro model.
5. Analyze the STAAD.Pro model for the new loads.
6. Export any changed or updated model data back to AutoPIPE via the PipeLink utility or the Export Macro.

**M. To import a piping model**

**Tip:** The scale, orientation, and origin of both the piping model and structural model should be the same.

1. From within Bentley AutoPIPE, export the pipe stress model using the PipeLink utility.

   **Note:** Refer to the AutoPIPE documentation for additional assistance on using this product.

2. Open a corresponding model in STAAD.Pro.
3. Select the **Piping** workflow.
   The Piping ribbon tab and pages open.
4. Either:
   - on the **Piping** ribbon tab, select **Interop > Import** in the **Models** group
   - click **Import** on the **Pipe Model dialog** (on page 3111).
   An **Open** dialog opens with the **Files of type** filter set for PipeLink files.
5. Select the **PipeLink file created from AutoPIPE** in the Files list box.

6. Click **Open**.

   A message dialog displays the status of the file import process.

   **Note:** If clashes are detected when importing, then the **Merging Support Connection dialog** (on page 3120) opens. This is used to specify if either the imported or local data should be used.

7. Click **OK** to dismiss the dialog.

   The **Support Connection Wizard** opens.

   **Tip:** Multiple models can be imported to a single STAAD.Pro project. Any actions are performed on the current active model as selected in the **Pipe Model** dialog.

   **Tip:** Imported data is saved with the structure upon exiting the Piping mode for later use.

**Related Links**
- **Pipe Model dialog** (on page 3111)
- **Merging Support Connection dialog** (on page 3120)
- **Support Connection Wizard** (on page 3113)

**M. To use the Support Connection Wizard**

1. Either:

   on the **Piping** ribbon tab, select the **Support Connection Wizard** tool in the **Connection** group

   or

   import a piping model (on page 878) as described above.

   The **Move Pipe Model** dialog opens.

2. Enter the offset distance between pipe and structural models and the click the **Next >** button.

   The **Pipe Nodes** dialog opens.

   The filtering options are All, Connected, Unconnected, V-Stop, or Anchor (relating to whether a connection to the STAAD.Pro model has been defined). When support type information is available the filter will be expanded to include these as well.

3. Select which nodes will be used by adding them to the Selected list and click the **Next >** button.

   The **Structure Beams** dialog opens.

   The filtering options are implemented with two combo boxes, one for the category and one to identify the subset within that category. Available filtering options are All, Group, View and Property.

4. Select which structure elements will be used by adding them to the Selected list and click the **Next >** button.

   The **Structure Node** dialog opens.

   The filtering options are implemented with two combo boxes, one for the category and one to identify the subset within that category. Available filtering options are All, Group and View.

5. Select which structure nodes will be used by adding them to the Selected list and click the **Next >** button.
The Parameters dialog opens.

6. Here you will set some parameters so the wizard can establish pipe connections and click the Next button.

The results of the Wizard will be displayed in the final dialog.

See "Parameter Page / Connection Finder" for additional details on these settings.

7. Review these results and if changes are necessary, you may click the Back button. Otherwise, click the Finish button to accept.

The results will be presented in a table with columns for pipe node id and for the structural item it is to be connected to. This second column will provide a drop list allowing the user to choose either “No connection” or one of up to 5 closest items. The items will be listed with the closest at the top. The initial state will be the closest item or ‘Ground’, if no good matches were found.

**Tip:** Manual connections can be generated using the following procedures.

**Related Links**
- Support Connection Wizard (on page 3113)

**M. To draw connections between piping supports and the structure**

1. On the Piping ribbon tab, select the Connection Support tool in the Connection group.

   ![Connection Support Tool](image)

   The mouse pointer changes appearance to the Support Connection cursor ( ).

2. Click a piping model support.

   A dynamic line is now attaches this support to the cursor.

3. Click either a node or a beam element in the structural model.

   The support association is shown as a dashed, red line in the view window. The Pipe Supports table (on page 3117) is updated to reflect the Connect To structural entity.

   **Note:** You may wish to edit the Dist. Along Beam value in the Pipe Supports table to control the exact connection location.

4. Repeat steps 3 and 4 to connect as many supports as needed.

5. Press the <ESC> key to exit the Support Connection cursor.

**Related Links**
- Pipe Supports table (on page 3117)

**M. To manually specify connections between piping supports and the structure**

1. Select the Supports page in the Piping workflow.

   The Pipe Supports table (on page 3117) opens.

2. Select the row of the Pipe Support Node you wish to connect to the structure.

3. Select if the support is Connected To either a Node or Beam.
**Note:** Ground supports are the default and are assumed to *not* be supported by the structural model.

4. Press <Tab>.
5. Type the connecting Beam or Node number in the **Structure Entity** cell for the Pipe Node.
   The connection association is shown as a dashed, red line in the view window.
6. Press <Tab> to update the model.
7. (Optional) (For Beam supports) Specify a distance along the beam, from the start node, to the connection point and then press <Tab>.
8. Repeat Steps 2 through 7 to connect as many supports as needed.

**Related Links**

- *Pipe Supports table* (on page 3117)

---

**M. To transfer load data for structural analysis**

1. On the **Piping** ribbon tab, select the **Transfer Loadings** tool in the **Loading** group.

   ![Transfer Loadings](image)

   The **Transfer Pipe Reactions to Structure Model** dialog (on page 3119) opens.

2. Make any changes to the load data as needed.
3. Click **OK**
   A Transfer Loads summary dialog opens to inform you of the status of the load data transfer.
4. Click the **OK** button to dismiss the dialog.
   The loads from the pipe stress supports are now added to the **Load & Definition** dialog in the model.

   **Note:** The structure is now ready to be analyzed for the imported pipe support loads.

**Related Links**

- **Transfer Pipe Reactions to Structure Model dialog** (on page 3119)

---

**M. To export model data for use in AutoPIPE**

Before you export the model data, you should analyze the structural model. Select the **Analytical Modeling** workflow and then on the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group. Return to the **Piping** workflow once the analysis is sucessfully completed.

1. On the **Piping** ribbon tab, select **Interop > Export** in the **Models** group.

   ![Interop Export](image)

   The **Export Revised Model** dialog (on page 3110) opens.

2. (Optional) Edit **User Name**
3. Click **OK**
   The **PipeLink for STAAD.Pro V8i** utility program opens.
4. Either:
Select an existing data exchanger file (file extension .pipelink) by clicking [...] or Create a new file by clicking Use Blank.

5. Either:
   - Select Export > Start Run.
   - or
   - Select the Run tool.

   The progress of the export process is displayed in the Output window. A message dialog opens to provide you with the status of the export.

6. Click OK.
7. Review any error or warning messages as needed.
8. Select File > Exit to close the utility program.

**Note:** Refer to the documentation included with the PipeLink plug-in for additional help in using this utility.

**Related Links**
- Export Revised Model dialog (on page 3110)

---

**M. To export STAAD.Pro model data into AutoPIPE**

**Tip:** The macro ToAutoPipePub.vbs is included with STAAD.Pro for the purpose of creating structural support data in AutoPIPE from a STAAD.Pro model. The resulting file contains only the support frame data for the current STAAD input file.

1. On the Utilities ribbon tab, select User Tools > Export Model to AutoPIPE in the User Tools group.

   The Export STAAD Model to AutoPIPE dialog (on page 3107) opens.
2. Select the AutoPIPE Neutral file (file extension .NTL) you wish to create or to which you wish to add data.

   **Tip:** Click [...] to select an existing AutoPIPE Neutral file.
3. Specify Job Information and Header data as necessary.
4. Select the appropriate system of Units.
5. Select an option for how the Member Properties are displayed in AutoPIPE.
6. Click OK.

   **Note:** If any invalid structural properties or specifications are found, a warning dialog opens to display these issues. Otherwise, a dialog opens to confirm the AutoPIPE Neutral file has been created.

**Related Links**

</table>

M. Bridge Deck workflow

STAAD.beava (Bridge Engineering Automated Vehicle Application) mode is integrated into the Bridge Deck workflow. This facility is used for generating loads for use in the analysis of bridge structures.

Overview

The general philosophy governing the design of bridges is that, subject to a set of loading rules and constraints, the worst effects due to load application should be established and designed against. The process of load application can be complex as governing rules can impose interdependent parameters such as loaded length on a lane, lane factors, and load intensity. To obtain the maximum design effects, engineers have to try many loading situations on a trial and error basis.

This leads to the generation of many live load application instances (and a large volume of output data) that then must be combined with dead load and other effects, as well. Bridge Deck is used to minimize the load application process while complying with national code requirements.

The program is based on the use of influence surfaces, which are generated by STAAD.Pro as part of the loading process. An influence surface for a given effect on a bridge deck relates its value to movement of a unit load over the point of interest. The influence surface is a three-dimensional form of an influence line for a single member (or, in other words, it is a 2D influence function).

STAAD.Pro will automatically generate influence surfaces for effects such as bending moments for elements, deflection in all the degrees of freedom of nodes, and support reactions. You then instruct the program to utilize the relevant influence surfaces and, with due regards to code requirements, optimize load positions to obtain the maximum desired effects.

Once the influence surfaces have been generated, they are saved and can be reused for any further investigation that may be required. These remain valid as long as the you do not altered the structural model. Changes to the structural model can alter the pattern of the influence surfaces and you must ensure that a further analysis takes place before any further processing.

Your engineering knowledge and judgement is critical in deciding which effects are required and at what position to obtain them. This is where you can save a lot of processing time and also can ensure critical positions are not missed.
**Bridge Standards**

The Bridge Deck mode supports the following standards:

- **UK**: BS 5400 Part 2 (on page 3132)
- **UK**: BD21/01 Chapter 5 (on page 3133) and Annex D (on page 3133)
- **American**: AASHTO ASD/LFD (on page 3134)
- **American**: AASHTO LRFD (on page 3135)
- **Indian**: IRC Chapter 6 (on page 3135)

All the relevant code instructions for loading definitions and traffic lane calculations are incorporated in BEAVA and, in cases where vehicle axle arrangements are not standard, it is possible to define a vehicle and save it in the library for use it in the analysis.

**Note**: It is not uncommon for local authorities to have superseding documents or amendments to national documents. It is the responsibility of the engineer to be familiar with these codes and input the appropriate parameters for loads.

BEAVA is fully integrated in STAAD.Pro and utilizes the same GUI for all input and output data.

**Roadway and Load Modeling**

You must define the width of the Roadway as straight or curved parallel lines. BEAVA then automatically calculates the following in accordance with the selected code:

- Number of Notional Lanes (Traffic Lanes)
- Influence lines along the center line of notional lanes
- Loaded length along the Lanes
- Critical location of uniformly distributed load
- Critical location of knife edge load
- Critical location of vehicle load
- Maximum effect value
- Associates effects values

Once the program has completed calculating the above, a text file containing the results is displayed on the screen. You can also then examine the results graphically.

Loading arrangements for the effects requested can be displayed on the model and, for every loading arrangement produced, you can instruct the program to generate a STAAD.Pro load case. The added live load cases can be combined with dead loads using the normal STAAD.Pro load combination generation. The final model can then be analyzed in STAAD.Pro and then post-processed.

**M. Using BEAVA**

There are a number of distinct stages in the use of the program. It is strongly advised to follow this order when using the program.
Tip: It is recommended that you work through the EX. Bride Deck Loading Example (on page 5033) to familiarize yourself with this process.

M. To open a model in the bridge deck workflow

1. Create a structural model—including member properties and support conditions— in STAAD.Pro.
2. Run an analysis on the structure.
3. Select Bridge Deck in the Workflows panel.

   Note: If you do not have a license for this module, you will not be able to proceed.

   The Bridge Deck ribbon tab opens.

M. To define a bridge deck

1. (Optional) If the mouse pointer is not already displayed as the Plate Cursor, in the Analytical Modeling workflow on the Geometry ribbon tab, select the Plates Cursor tool in the Selection group.

2. Select the elements and/or members that will be used to define the bridge deck area of the models.
3. In the Bridge Deck workflow on the Bridge Deck ribbon tab, select the Create Deck tool in the Deck group.

   The Save Deck as dialog opens.
4. (Optional) Type a Name for the deck.
5. Click OK.

M. To generate influence surfaces

To generate influence surfaces for the currently selected deck, do the following.

1. On the Bridge Deck ribbon tab, select the Loading > Influence Surface Generator tool in the Loading group.

A temporary STAAD input file (filename_deck.std) is sent to the STAAD analysis engine for processing. The STAAD Analysis and Design dialog opens to display the progress. When the analysis is complete, the dialog closes automatically.

M. To define a roadway

To define a roadway (i.e., carriageway in some regions), do the following.
1. Either:
   Select a deck from the View window.
   or
   On the Bridge Deck ribbon tab, select the Select Deck tool in the Deck group and then select one of the defined decks from this list.

2. On the Bridge Deck ribbon tab, select the Define Roadway tool in the Deck group.

   The Roadways dialog (on page 3123) opens.

3. Click New.
   The Define Roadway dialog (on page 3125) opens.

4. Specify the distances from the origin to each curb edge.
   The preview updates to display the roadway on the currently selected deck.

5. Click OK.
   A new roadway is now added to the Roadways list in the Roadways dialog and is outlined in blue on the deck in the active view window.

6. Click Close.

M. To generate loads on the roadway

1. On the Bridge Deck ribbon tab, select the Loading > Run Load Generator tool in the Loading group.
   The Load Generator Parameters dialog (on page 3130) opens.

2. On the General tab, select the appropriate Design Code.
   The <code> tab updates to reflect this selection.

3. Select the appropriate Limit State.

4. Select the <code> tab.

5. Make the code-specific selections for vehicles, road conditions, multiple presence factors, and impact factors.

6. Select the Node Displacements, Support Reactions, Beam End Forces, or Plate Center Stress tab.

   Note: An action must be defined for which the maximum results determine the placement of the moving loads.

7. Specify a structural object number, direction of action, and sign of effect.

8. Repeat steps 6 and 7 as many times as needed.

9. Click OK.
   The program analyzes the deck to obtain the critical load positions for the specified action.

A summary of the analysis is opened in your default text editor (e.g., Notepad). The file (named filename_deckx.out) is saved in the same location as the input file. Close the text editor once you have completed reviewing this file.

The placement of the loads for each effect requested may be reviewed.
M. To transfer the loads to STAAD.Pro

To transfer the generated load cases to STAAD.Pro for analysis and design, do the following.

1. On the Bridge Deck ribbon tab, select the Loading > Create Loading in STAAD Model tool in the Loading group.
   A message dialog opens to confirm the load was successfully added in the STAAD input file.
2. Select the Analytical Modeling workflow.
3. On the Loading page, review the loads added to the input file in the Load & Definitions dialog.

   **Note:** One load was added for each action requested in the Load Generators Parameters dialog.

4. (Optional) Specify additional analysis commands or design parameters as needed.
5. On the Analysis and Design ribbon tab, select the Run Analysis tool in the Analysis group.

M. Checking Your Model

STAAD.Pro comes with a number of tools used to check your structure and model objects.

M. To check for multiple structures

To check for multiple, independently defined set of entities in your model, use the following procedure.

The STAAD.Pro analysis engine can accommodate multiple structures in a single model. However, this check allows you to confirm the number of detected structures to prevent an unintentionally defined model.

1. On the Utilities ribbon tab, select the Structure Tools > Multiple Structures tool in the Geometry Tools group.

   The List of Structures dialog opens.

2. (Optional) Select a structure name in the list.
   The entities detected in this structure are selected in the view window.

M. To check for warped plates

A warped plate is defined as a four-noded plate whose nodes do not lie on the same plane. This tool detects such plates.

You can set the tolerance for warped plates by first setting the Tolerance for Warped Plate Element Detection value on the Options dialog Tolerance tab. Only plates whose angular deviation exceeds this tolerance value will be displayed.

For this check, warping is defined as excessive angular deviation between all vertex normals.

1. Select one or more plates in the model.
2. Select the **Plate Tools > Check for Warped Plates** tool in the **Geometry Tools** group on the **Utilities** ribbon tab.

If any warped plates are detected, the **Detect Warp Plates** dialog opens. A list of all selected plates and their maximum angular deviation is displayed. The global coordinates for a selected plate are displayed below.

![Detect Warp Plates dialog]

3. (Optional) Click **Highlight**
4. (Optional) Click **Delete**

**Tip:** You can undo this action through the **Undo** tool in the main interface.

5. Click **Close** when you have completed reviewing warped plates.

An example of such an element is demonstrated in the following STAAD input.

```
STAAD SPACE
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0; 3 10 10 0; 4 10 0 2
ELEMENT INCIDENCES SHELL
21 1 2 3 4
FINISH
```

Nodes 1, 2, and 3 lie in the XY plane at Z = 0, but node 4 has a Z coordinate of 2, thereby causing the plate to become non-planar.

The warped plate check sub-divides the quad element into two sets of triangles: one with a diagonal from point 1 to point 3 and another diagonal from point 2 to point 4. These triangles do not lie in the same plane so an angle is formed between them at their shared edge. The largest angle between adjacent triangles in the warped quad element is compared against the tolerance threshold. If this tolerance angle is exceeded, then the plate is reported as excessively warped.
M. To check for and remove duplicate entities

To detect the presence of and remove instances of nodes, beams, plates, etc. which are duplicates, use the following procedure.

One definition of duplicate nodes is that they are 2 or more nodes, having distinct node numbers, but the same X, Y, Z coordinates. For example, if node number 5 has coordinates of (7, 10, 0), and node 83 also has coordinates of (7, 10, 0), node 5 and 83 are considered duplicate. However, STAAD allows you to expand the definition of this term to include nodes separated by any distance. When this menu is selected, the following message box pops up, asking the user to specify a tolerance.

Duplicate members are 2 or more members, having distinct member numbers, but connected between the same 2 nodes. For example, if there are 3 members, say, 17, 46 and 75, all connected between the nodes 105 and 117, those 3 members are considered duplicate. The order of the node incidence is disregarded during this check. For example, if member 17 has 105 as its first node, 117 as its second, and member 46 has 117 as its first node, 105 as its second, they are still treated as duplicate.
A similar definition is applicable for duplicate triangular or quadrilateral plates. Plates are considered duplicates if they share the same vertex nodes, regardless of order.

1. Depending on the entity type you are checking, select one of the following tools from the Utilities ribbon tab in the Geometry Tools group:

   - **Nodes**
     - Node Tools > Check Duplicate Nodes
   - **Beams**
     - Beam Tools > Check Duplicate Beams
   - **Plates**
     - Plate Tools > Check Duplicate Plates

   (Nodes only) The **Remove Duplicate Nodes** dialog opens.

2. (Nodes only) Type a distance in the **Enter Tolerance** field and click the **OK**.

   The tolerance is the value used to define the distance at which nodes are to be considered separate or a duplicate. In some cases, the process of creating the model can result in nodes that are a minuscule distance apart. Specifying a tolerance greater than zero allows the program to consider those nodes as duplicates and allows you to process them as needed.

   The program reviews the model for any duplicates of the selected model element type (using the tolerance for Nodes).

   - If no duplicates are found, a message is displayed.
   - If duplicates are detected, the List of Duplicate Nodes / Members / Plates dialog opens. Each entry in the list contains two or more entities that the program has detected to be duplicates.

3. Select a duplicate set in the list and then click **Merge >>** to remove the duplicate from the model.

4. Select one of the items detected as a duplicate in the **Node / Member / Plate To Keep** drop-down list and then click **OK**.

   The remaining duplicates are removed and other model entities which refer to those duplicates now reference the selected (merged) entity.

5. Repeat steps 3 and 4 as necessary to review all duplicates of the entity type selected.

6. Click **Close**.

**M. To detect and remove zero length members**

A zero length member is one of the undesirable consequences of having duplicate nodes in the structure. A member connected between duplicate nodes, which have the same (X,Y,Z) coordinates, will have a length of zero (or nearly zero).

1. On the Utilities ribbon tab, select the Beam Tools > Check Zero Length Members tool in the Geometry Tools group.
   
   The **Zero length beams** dialog opens.

2. (Optional) Type a different tolerance in the **Enter Tolerance** field.

   Since duplicate nodes can be two or more nodes separated by any user-defined distance, zero length members too can be defined as members of any user-defined length. This distance is the tolerance used in the process of detection.

3. Click **OK**.

   If no members of zero length are detected a message is displayed.
If one or more zero length members are detected, the Detect Zero Length Member dialog opens.

4. Select a zero length member in the list and then click Delete to remove the beam.

**Tip:** You can click Highlight to select the member in the View window (though most zero length members are difficult to see unless at a very high magnification). Then select the Properties tool on the Beam ribbon tab to open the Beam dialog for the zero length member.

5. Repeat Step four as necessary until all zero length members are removed.
6. Click Close.

### M. To check for overlapping collinear members

1. On the Utilities ribbon tab, select the Beam Tools > Check Overlapping Colinear Members tool in the Geometry Tools group.

   If no overlapping collinear members are detected, then a message dialog opens with that message.

   If one or more overlapping collinear members are detected, the Overlapping Collinear Beams dialog opens.

2. Select the overlapping members pair and the Highlight option to select the beam(s) in the Active View window.

3. The members in the Active View window can be manipulated or deleted as necessary while the Overlapping Collinear Beams dialog is open.

```
An example of 2 members which would qualify as overlapping collinear are:

STAAD SPACE
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0; 3 10 10 0; 4 10 0 0; 5 13 10 0; 6 -4 10 0;
MEMBER INCIDENCES
1 1 2; 2 2 3; 3 3 4;
101 5 6
FINISH

Here, members 2 and 101 are overlapping collinear. Member 2 is entirely confined within the span of member 101, and collinear, but they are not attached to each other.

Another example is:

STAAD SPACE
UNIT FEET KIP
JOINT COORDINATES
1 0 0 0; 2 0 10 0; 3 10 10 0; 4 10 0 0; 5 13 10 0; 6 -4 10 0;
MEMBER INCIDENCES

101 2 5
FINISH

Here, again, members 2 and 101 are overlapping collinear. But even though they are connected to each other at node 2, again member 2 is entirely confined within the span of member 101, and collinear.
```
M. To change a beam incidence

To change the incidences of a selected set of beams, use the following procedure.

1. Select one or more members in the view window.
2. On the Utilities ribbon tab, select the Beam Tools > Beam Incidence tool in the Geometry Tools group.

The Redefine Incidence dialog opens.
3. Select an incidence definition to use:
   - Switch incidences of selected beams
   - Set the incidence order of the selected beams so that the start node is close to the origin than end node
   - Set the incidence order of the selected beams so that the start node is farther from the origin than end node
4. Click OK.

- M. Member Orientation (on page 794)

M. To detect and remove orphan nodes

To detect and then remove nodes which are not connected to any other model entity (i.e., “orphan nodes”), use the following procedure.

In the process of modeling, disconnected nodes can be created in your model.

1. On the Utilities ribbon tab, select the Node Tools > Orphan Nodes tool in the Geometry Tools group. Any detected orphan nodes are selected in the view window.
2. To remove these orphan nodes, on the Utilities ribbon tab, select the Node Tools > Remove Orphan Nodes tool in the Geometry Tools group. The detected orphan nodes are deleted.

M. To display the distance between two nodes

To temporarily display the dimension between two nodes in the active View window, use the following procedure.

1. On the Utilities ribbon tab, select the Node Tools > Node to Node Distance tool in the Geometry Tools group.
The mouse pointer changes to the Node to Node Distance cursor.

2. Click on any two nodes in succession in the active View window.
   A dimension call out is added between these two nodes.

3. Repeat step 2 to dimension as many distances as needed.

4. Either:
   
   Press the <Esc> key

   or

   Select the **Node to Node Distance** tool again
   The mouse pointer returns to the normal selection mode.

M. To display beam lengths

To display the lengths of each analytical member, use the following procedure.

To dimension only the members in a selection, select those members before starting this procedure.

1. On the **Utilities** ribbon tab, select the **Beam Tools > Dimension Beams** tool in the **Geometry Tools** group.

   The **Display/Remove Dimensions** dialog opens.

2. Select the option for which beams to be dimensioned:

   **To...**                                           **Select...**
   dimension all the beams in the current view window  Dimension to View
   dimension only the beams you selected before step 1  Dimension to Selected Beams
   dimension a comma separated list or range of beams   Dimension to List

3. Click **Display**.

4. (Optional) To remove the dimensions, select the **Remove** option and then click **Remove**.

5. Click **Close**.

Any new members will not be dimensioned. You must repeat this procedure to display their dimensions.

**Related Links**

- **Display/Remove Dimensions dialog** (on page 3097)

M. To check for negative volume solids

To check for solids that would result in a negative volume in the analysis, do the following.

This check uses the Jacobian matrix determinate to determine if any of the solids have a negative or indeterminate volume, which would result in an analysis error.

1. On the **Utilities** ribbon tab, select the **Solid Tools > Negative Volume** tool in the **Geometry Tools** group.
The List of Solids dialog opens.

2. Select any solid number in the list to select it in the view window.
3. Click Close.

**M. Physical Modeling workflow**

You can use STAAD.Pro Physical Modeler to model a “physical” structure and then re-import that data back into the STAAD.Pro environment for loading, analysis, and design.

**M. Using the Physical Modeler**

You can model structure geometry, specifications, and many loads with the STAAD.Pro Physical Modeler.

You must be a physical model with an empty STAAD project. Existing analytical models cannot be opened in the physical modeler.

When you open a model that was created using the physical modeler, you will be prompted if you want to open the model in the physical modeler environment.

1. Select the **Physical Modeling** workflow.

The STAAD.Pro Physical Modeler window opens.

Refer to the **STAAD.Pro Physical Modeler help** for details on how to use that module to model your structure.

**M. To drop the associated physical model**

To remove the associated physical model from the current STAAD input file, use the following procedure.

**Caution:** This procedure cannot be undone. Once a physical model has been dropped, that model can no longer be opened within the **Physical Modeling** workflow.

When a physical model is associated with a STAAD input file, many tools in the **Analytical Modeling** workflow as well as portions of the input file in the STAAD.Pro Editor are disabled. This is intended to prevent making changes which would potentially corrupt the association between the physical and analytical models. However, there are times when you may need to drop this association to make changes to the analytical model.

1. Select the **Analytical Modeling** workflow in STAAD.Pro.
2. On the **Utilities** ribbon tab, select the **Drop Physical Model** tool in the **Physical Model** group.
A warning dialog opens asking you to confirm you want to break this link.

3. Click Yes.

The input file is re-opened in STAAD.Pro as an analytical model only.

M. Building Planner workflow

The Building Planner workflow integrates STAAD Building Planner into STAAD.Pro. This is used to generate concrete building models which can then be analyzed in STAAD.Pro and detailed using the Advanced Concrete Design workflow.

M. To start a STAAD Model in the Building Planner workflow

   The New page opens to the Model Info tab.
2. Specify the File Name, Location, and Units as necessary.
3. Select the Building option for the Type of model.
4. (Optional) Select the Job Info tab to add project member names, dates, project description data, etc.
   You can also associate your STAAD project with a ProjectWise Project here.
5. Click Create.

The STAAD.Pro window closes and the STAAD Building Planner application opens. The Start dialog opens.

6. Enter the project details, including No of Levels and Founding Depth.
7. Click Create Project.
   The New Plan dialog opens.

You are now ready to start adding details for the first floor plan and modeling your building structure.

• GS. Start Page (on page 50)

M. Plans

Plans are building floor layouts (slabs, columns, and beams) which can be used for one or more floors in your building model. This allows you to rapidly model a building in which multiple floors have the same geometry, structure, and loads.

M. To Create a New Building Plan

   The New Plan dialog opens.
2. Specify the general details:
   a. Type a **Plan** name.
   b. (Optional) Select a **Floor type**
   c. Type the **Height of Level Above** (floor-to-floor height).
   d. Click the **Assign Levels** drop-down to assign plan names to each level of the building.

   **Note:** The number of levels is specified in the **Start** dialog.

3. Select the **Create Plan Graphically (Do not import)** option to create a new plan.
   Optionally, you may import the plan from a drawing (on page 897), a PlanWin file, or from another plan in this project (if there is another).

4. Specify the plan details and source (i.e., CAD file, drawing an plan in STAAD, or PlanWin plan).

5. Specify the loads on this plan:
   a. Enter the Slab Loading Parameters.
   b. Enter the Beam Loading Parameters.

6. Select the **Concrete Grade** and **Steel Grade** used in this plan.

7. Click **Create Plan**.
   If the plan was not assigned to any levels in Step 2d, then a warning message displays. Click **Yes** to proceed. Otherwise, the **Slab Details (Rectangle)** dialog opens.
8. Specify the slab details:
   a. Type coordinates for the Position
      
      **Tip:** Leave default to accept origin.
   b. Type material, geometry, and loading parameters.
   c. Specify the direction the slab spans: Two Way, One Way, or Distribute on Selected Edges.

   **Tip:** The Length and Breadth values specified determine the recommended default direction.

9. Click **OK**.
   The slab is drawing in the graphical view.

**M. To Import a Building Plan**

The Building Planner can import plan data from other sources, such as PlanWin files or CAD drawings.

**Note:** The plan data must be in the correct format in a CAD drawing (.dxf file format). The correct units and scale must used in the drawing.
Modeling
M. Building Planner workflow

- Slab data must be in a layer named “Slab”. Only closed polylines or light weight polylines can be imported.
- Column data must be in a layer named “Column”. Use circles of any appropriate radius to mark the columns.
- Beam data must be in a layer named “Beam”. Use lines to mark the beam centerlines.

   If you have not yet specified project details, the Start dialog opens. Otherwise, the New Plan dialog opens.

   **Note:** Alternately, you can select Edit > Import Plan File to replace the current plan with imported plan data using the Import Plan File dialog.

2. Specify the general details:
   a. Type a Plan name.
   b. (Optional) Select a Floor type
   c. Type the Height of Level Above (floor-to-floor height).
   d. Click the Assign Levels drop-down to assign plan names to each level of the building.

   **Note:** The number of levels is specified in the Start dialog.

3. Select either:
   CAD Center line Input (DXF)
   or
   Plan from PlanWin file
   or
   Existing plan from current project

4. Navigate to and select the file you want to use for either CAD or PlanWin file options and click Open.
5. If the selected PlanWin file has multiple plans, select the plan name you want to import.
6. Click OK.

M. To Edit Plan Properties

1. Select View > Plan Properties.
   The Plan Properties dialog opens.
2. Type a new Plan Name or Height of Floor Above value.
3. Click OK.

M. Slabs

Parametric slabs are used to model portions of physical slabs in a building floor. This allows you to model thickened slabs or other complex layout geometry easily.

M. To Add a Rectangular Slab

To add a rectangular slab to the current plan, use the following steps.

1. In a plan workspace, select Slab > Create Slab Rectangle.
2. Click a start and end corner for the slab in the graphics window.
   The start corner “snaps” to the nearest existing slab corner. You can input any corner using the X and Y offsets in t.
   A gray rectangle connects the initial point to your mouse pointer to indicate the general direction of the slab. Exact slab dimensions are specified in the next steps, though.
   The Slab Details (Rectangle) dialog opens.
3. Specify the slab details:
   a. (Optional) Type X Offset Y Offset
      Tip: You may use negative numbers here.
   b. Type material, geometry, and loading parameters.
   c. Specify the direction the slab spans: Two Way, One Way, or Distribute on Selected Edges.
      Tip: The Length and Breadth values specified determine the recommended default direction.

   Tip: Cantilevered slabs can be specified using the Distribute on Selected Edges option and clicking a single, supporting edge.
4. Click OK.
The slab is drawn in the Plan | Slab page graphical view.

**Tip:** If the slab has been drawn beyond the extents of the window, right-click anywhere *not* on a slab and select **Zoom Extend** from the pop-up menu.

Describe the results of the action.

5. Repeat Steps 2 through 4 as necessary to continue drawing slabs.

**Tip:** Press `<Esc>` to quit using this tool.

---

**M. To Add an Irregular Shape Slab**

To add an irregularly shaped slab to the current plan, use the following steps.

1. In a plan workspace, select **Slab > Create Irregular.**
2. Click an initial corner for the slab.
3. Click another corner in either a clockwise or counterclockwise progression from the previous corner.
   The **Point Select** dialog opens.

   **Tip:** The **Point Selection** dialog will not open if the program detects you have indicated an existing slab corner.

4. (Optional) Specify an X Offset and Y Offset value (relative to the point highlighted in a red circle), Distance, and Angle value to place the point at another location.
5. Click **OK.**
6. Repeat steps 3 through 5 to select each additional vertex point on the slab.
7. Right-click to stop adding corners.
   The **Slab Details (Irregular)** dialog opens.
8. Specify the slab details:
   a. Type label, material, geometry, and load parameters.
   b. Specify the direction the slab spans: **Two Way**, **One Way**, or **Distribute on Selected Edges**.

   **Tip**: The resulting dimensions determine the recommended default direction. If one or more slab spanning directions is determined to be unsuitable based on the dimensions, it is disabled.

   **Tip**: Cantilevered slabs can be specified using the **Distribute on Selected Edges** option and clicking a single, supporting edge.

9. Click **OK**.
   The slab is drawn in the Plan | Slab page graphical view.

10. Repeat Steps 2 through 9 to continue drawing irregularly shaped slabs.

   **Tip**: Press `<Esc>` to quit using this tool.

M. To Edit Slab Properties

   To edit the parameters of an existing slab, use the following steps.
**Note:** The label or material and load parameters of a slab may be edited. To edit they geometry, you must deleted and redraw a slab.

1. In a plan workspace, select **Slab > Select/Unselect**.
   
   **Tip:** You can use some of the other selection tools to refine your selection of slabs as necessary.

2. Select a slab in the graphical view.
   
   **Tip:** Hold <Ctrl> to select multiple slabs.

3. Either:
   
   Select **Slab > Set Property and Loads for Selected Slab/s**
   
   or
   
   Right-click and select **Set Property and Loads for Selected Slab/s** from the pop-up menu.

   The **Set Slab Property and Loading** dialog opens.

   ![Set Slab Property And Loading](image)

   4. Check the options for each parameter you want to edit for all selected slabs and then type or select the value.

   5. Click **OK**.

**M. Columns**

**M. To Add a Column**

To add a single column, use the following steps.

1. In a plan workspace, select **Column > Create Column**.

2. Click the nearest slab corner or edge where you want to place a column.

   The nearest slab corner is highlighted with a red circle. The **Column Details** dialog opens.
3. Type column details:
   a. (Optional) Type a custom **Mark**
      
      **Note:** This must be unique to the plan.
   
   b. Type a face **Size** (square column).
      
      All initial column sizes are assumed to be square. Columns can later be resized manually or designed.
   
   c. (Optional) Type an **X Offset Y Offset**
      
      The coordinates of the column are displayed for reference.
   
   d. (Optional) Type an **Angle Distance**

4. Click **OK**.
   
   The column is drawn in dark blue on the graphical view.

5. Repeat Steps 2 through 4 to continue placing columns.

### M. To Add Columns Automatically to the Entire Plan

To place columns automatically at detected points on the entire plan, use the following steps.

1. In a plan workspace, either:
   
   select Column > **Auto Column**, or
   
   or
   
   select Column > **Locate Column**.

   Columns are added at all slab corners on the floor, unless you selected the Locate Column option. In that case, the first detected column location is selected and the Locate Column dialog opens.
2. (Optional) If you selected the Locate Column feature, either:
   Specify the current column mark, offset, and orientation, or
   or
   click **Skip** to skip to the next detected column location, or
   or
   click **Skip Line** to skip all the detected locations in the current column line, or
   or
   click **End** to stop adding columns.

3. Repeat Step 2 as needed until you have reached the end of the detected column locations.

If you used the auto column feature or if you neglected to skip a location, you may need to delete any unwanted columns (e.g., those added at the end of a slab intended to cantilever), move columns, or edit the parameters of columns which are different than the default values for the plan.

M. Beams

M. To Create a Beam

To add a single beam, use the following steps.

**Note:** The **Auto Beam** tool will delete any existing beams on the plan. You may want to use the Auto Beam feature prior to drawing individual beams.

1. In a plan workspace, select **Beam > Create Beam**.
2. Select the start and end support points for the beam.
If beams are drawing over columns or existing beams, the new beam will be broken into separate objects once placed.
The nearest slab corners are highlighted with red circles. The **Beam Details** dialog opens.

3. Type the beam details:
   a. (Optional) Type a custom **Mark**
      
      **Note:** This must be unique to the plan. If you are drawing multiple beams over columns or existing beams, the mark will be incremented for the additionally created beams.
   
   b. Type a **Breadth** and **Depth** for the beam size.
   c. Select the **Grade** of material.
   d. (Optional) To include the uniform dead load for the beam, type a value or click **Compute Beam Load**
      
      **Note:** If Compute is used, the Beam Load dialog opens with the specified beam dimensions. You can specify a material Density and include options for walls supported by the beam.
4. Click **OK**.
   The beam is drawn in green on the graphical view.

5. Repeat Steps 2 through 4 to continue placing beams.

### M. To Add Beams Automatically to an Entire Plan

To place beams automatically at detected points on the entire plan, use the following steps.

1. In a plan workspace, select **Beam > Auto Beam**.
   If there are any existing beams, a warning message that they will be deleted opens.

2. Click **OK**.
   The **Auto Beam Details** dialog opens.
3. Type the beam details:

**Note:** The internal and external (exterior slab edge) beams can be specified separately.

a. Type a **Breadth** and **Depth** for the beam sizes.

b. (Optional) To include the uniform dead load for the beam, type a value or click **Compute Beam Load**

**Note:** If Compute is used, the Beam Load dialog opens with the specified beam dimensions. You can specify a material Density and include options for walls supported by the beam.
c. Select the **Grade** of material.

d. Type the **Cover to Rebars** and **Flange Dimensions** used for design.

4. Click **OK**.

Beams are added at all slab edges on the floor.

---

**M. To Specify Beam Continuity**

To specify continuous beams over supports, use the following steps.

Building Planner uses a window to specify continuous beams for the entire plan. It is typically best practice to draw all beams for the plan before performing this procedure.

1. Select **Beam > Modify Beam Continuity**.
   The **Continuous Beam** window opens.

2. You can specify continuous beams individual for finer control or allow the program to autodetect all continuous beams:
To... | Select...
---|---
select individual beam segments to create continuous beams manually | Modify Data > Mark/Unmark
allow the program to detect all continuous beams automatically | Modify Data > Auto Mark Continuous Beam

If you used the auto mark option, then all beams that the program detects as having possible continuity over supports are marked in light purple. Proceed to Step 5.

3. Click a series of beams you want to mark as continuous. Each beam selected is highlighted in light red. You can click a beam segment again to unmark it.
4. Select Modify Data > Create. The selected beam segments are marked in light purple.
5. Repeat Steps 2 through 4 as necessary to continue to mark individual beam lines as continuous.
6. When you are finished marking continuous beams, either:
   - click the X in the top, right-corner of the Continuous Beam window, or
   - press <Alt+F4>

If you have marked beams as continuous, you must finalize the plan including continuity.

### M. To Edit Beam Properties

To change beam properties, use the following steps.

**Tip:** If the Beam Loading Errors window indicates that beams intended to be cantilevered are not supported, simply right-click on the beam and select Cantilever from the pop-up menu.

   **Tip:** You can use some of the other selection tools to refine your selection of beams as necessary.
2. Select a beam in the graphical view.
   **Tip:** Hold <Ctrl> to select multiple beams.
3. Either:
   - select Beam > Set Property and Loads for Selected Beam/s, or
   - right-click and select Set Property and Loads for Selected Beam/s from the pop-up menu

The Set Beam Property and Loading dialog opens.
4. Check the options for each parameter you want to edit for all selected beams and then type or select the value.

5. Click OK.

M. To Specify Beam Design Parameters

To control some of the various design parameters, use the following procedure.

1. In a plan workspace, select Analysis > Design Parameters.

   The Design Parameters dialog opens.

2. Make changes to the design parameters as necessary.
3. Click OK.

**M. Frames**

**M. To Finalize a Plan**

To finalize a plan for use in a building frame, use the following steps.

In order to complete a 3D frame model using the plan data, you must first finalize the layout of a plan. If you select the Frame page without having finalized plans, a warning message is displayed.

1. In the plan workspace, either:
   - select **Analysis > Finalize Plan (with Continuity)**, or
   - select **Analysis > Finalize Plan (without Continuity)** to ignore continuity between beams, or
   - A message dialog opens to indicate the plan was finalized. If any errors are detected, they will be highlighted in a pop-up window.

If any changes are made to the plan, you must repeat this procedure.

**M. To Create a 3D Frame**

In order to create or edit 3D frames, any changes to plans must first be finalized.

1. In the 3D Frame workspace, select **Assign > Level Properties**.
   - The **Level Information** dialog opens.
2. Click Add Level to add another level and then click OK to confirm.
3. For each level, click in the Plan column to select a plan name from the drop-down list.

   **Tip:** Use the autofill arrows below the table to copy the plan name to rows above or below a selected row, or to all rows above or below.

4. Click OK. The 3D Frame is created.
5. (Optional) Select View > 3D View.

**M. To Create a Shear Wall**

Shear walls created by the Building Planner are analytically columns with the dimensions of the wall they represent.

1. Select Assign > Define Shear Wall.
2. Click the columns or slab corners to define the start and end of the shear wall in plan.

   The points are highlighted with gray-filled, red circles in the view window. The Define Shear Wall dialog opens.
3. Specify the shear wall parameters: as necessary
   a. Type a Mark to label the wall.
   b. If a shear wall is not continuous from base to roof, clear the check mark in the Create column for that level.
   c. Type an X Offset and Y Offset value to move the wall with respect to the selected start point.
   d. Type B and D dimensions to specify a wall size.

4. Click **OK**.
   The shear wall is drawn in dark red in the plan.

5. Repeat Steps 2 through 4 as necessary to continue adding shear walls.

   **Tip:** Press `<Esc>` to quit using this tool.

## M. To Change Supports

To change boundary conditions for the 3D frame, use the following steps.

The supports are at each column or wall base at the first (lowest) level in the building frame. Initially, all supports are assumed as Fixed.

1. Select **Assign > Support Specification**
The **Support Specification** dialog opens.

2. Select the one or more columns or walls.

   **Tip:** Use the Selection drop-down list to change the selection method.

3. Right-click on a column or wall and select **Support Condition - mark** from the pop-up menu.

   The **Support Information** dialog opens.
4. Select the **Support Options** to use.
5. For **Fixed But** option, either:
   - specify the **Release-Spec**
   - or
   - **Spring-Spec** and spring constant for each degree of freedom as necessary.
6. Click **OK**.
7. Repeat Steps 3 through 6 for each support you want to change.
   - **Tip:** The support type is color-coded in the **Support Specification** dialog.
8. Click the **X** in the top, right-hand corner of the **Support Specification** dialog when you are finished making changes to the supports.
   - The **Support Details** table updates with the changes.

**M. To Specify Member Releases**

To change member end release details for the 3D frame, use the following steps.

All beams are initially assumed as fully fixed at both ends.

1. Select **Assign > Member Release (Beams)**.
   - The **Member Release** dialog opens.
2. (Optional) Select the level from the drop-down list of level numbers in the tool bar.

**Tip:** The current level and plan name are displayed in the status bar.

3. Right-click on a beam and select **Release Details-mark** from the pop-up menu.

**Tip:** The **Member Release** dialog contains some tools to select and make release changes to multiple members, such as all primary or secondary beams or all beams along a column line. These tools allow you to select the levels to which you want to apply these release specifications as well.

The **Beam Release Information** dialog opens.
4. Check the boxes for each degree of freedom to release at either end of the member and type a percent release value for each release direction.

Tip: The default release of 99% is intended to represent a full member release.

5. Click OK.

6. Repeat Steps 2 through 6 for each member you want to edit release specifications.

Tip: The member release specifications are color-coded in the Member Release dialog and indicated with dots on each member.

7. Click the X in the top, right-hand corner of the Member Release dialog when you are finished making changes to the member releases.

The Beam Release Details table updates with the changes.

M. To Change Column Size, Orientation, and Alignment

To change a column size and orientation, use the following steps.

1. Select Assign > Column Sizing and Orientation.

The Column Sizing dialog opens.
2. Select a column in the main graphical view. The selected column is highlighted in a red circle and the Mark is displayed. The column orientation and offset are displayed in the right-hand views.

3. To change the column orientation (i.e., Beta angle):
   a. Click a different axis of orientation in the lower, right-hand graphic or click +90 to rotate the column 90°
   b. Click Update Offset Data & Beta Angle.

4. To change the column offset:
   a. Click one of the column faces in the middle, right-hand graphic.
   b. Type an offset value in the indicated units.
   c. Repeat steps 4a and 4b to specify offsets in a different axis.
   d. Click Update Offset Data & Beta Angle.

5. To change a column size:
   a. Click Re-Size Column.

   The Design Column: <mark> dialog opens.
b. Type initial design parameters in the fields.

**Tip:** You can use the Check Column feature to perform a design check on the current column size.

c. Select a Column Shape.

d. Click Design Column.

The column size (Breadth and Depth) at each floor are updated based on the design parameters and specified building loads.

e. (Optional) You can manually type changes to the table values to further refine the design.

**Tip:** Use the automatic fill buttons below the table to copy values up or down the currently selected row.

f. Click OK.

The column diagrams are updated in the Column Sizing dialog.

6. Repeat Steps 2 through 5 for each column you want to change.

7. Click the X in the top, right-hand corner of the Column Sizing dialog when you are finished making changes to the column sizes and orientation.

The Beam Release Details table updates with the changes.
M. To Modify Wind Parameters

To specify parameters for lateral wind loads, use the following steps. The wind load parameters are input per the following codes:

- UBC 97
- IS 875-1987
- ASCE7

1. **Select Assign > Wind Parameters.**
   
   **Tip:** You can also double-click any of the wind load parameters in the Lateral Load dialog.

   The Wind Parameters dialog opens.

   ![Wind Parameters Dialog]

2. Select the **Design Code** from the drop-down list.

3. Either:
   
   Select the appropriate **City** in the drop-down list (recommended)

   or
Type a Wind Speed value directly.

4. Either:
   Select the Life Span (yrs) for which the building is to be designed from the drop-down list (recommended)
or
   Type a Risk Coeff (K1) value directly.

5. Type Height Below Ground and Parapet Wall values, in the units indicated.

6. Type a Gust Factor value.

7. Select the Terrain Category from the description list.

8. Click OK.

You can now review the calculated wind loads by selecting Frame > Wind Effect. In the Wind Effect dialog, select the different directions to see the distributed wind intensity on each floor. Selecting a column in the table displays the wind intensity values at the top and bottom of each floor along that column.

M. To Modify Seismic Parameters

To specify parameters for lateral seismic loads, use the following steps.

The seismic load parameters are input per the following codes:

- UBC 97
- IS 1893-2002

1. Select Assign > Seismic Parameters.

   The Seismic Parameters dialog opens.
2. Either:

Select the appropriate City in the drop-down list (recommended)

or

Type Seismic Coefficient and Seismic Zone values directly.

3. Specify a Response Reduction Factor for the building:
   a. Click [...] adjacent to the Response Reduction Factor field.
      The Response Reduction Factor dialog opens.
   b. Select the appropriate row in the Building Frame Systems description list.
   c. Click OK.
      The Response Reduction Factor is updated.

4. (Optional) Specify or select additional seismic parameters as necessary:
   a. Type an Importance Factor value.
   b. Type a Damping Factor value.
   c. Select the type of soil on site from the Rock/Soil Factor drop-down list.
   d. Select the Combination Method from the drop-down list.
   e. Type the Base Shear Scale Factor value.

5. Select if brick infill panels are present in the building structure to determine the Natural Time Period.

   Tip: Click Details to see the values used in evaluating Px and Pz.

6. Click OK.
M. To Modify the Load Combinations

The Building Planner mode uses building combinations per the Indian code by default. You can modify, remove, or add individual load combinations as necessary.

1. Select Tools > Load Combination. The Loading Combination dialog opens.
2. Make any changes to the load combinations necessary:
   - To...
     - change the load factor on a load type for a particular load combination
       Do the following...
       type the new load factor in the corresponding cell
     - add a new load combination
       click Add and type the load factors for each load type
     - remove an existing load combination
       select the load combination row and click Remove
     - set the current load combinations as the default in Building Planner mode
       click Set as Default
     - restore the default load combinations (i.e., the code load combinations)
       click Load Default Combinations
3. Click Update.
4. Click [X] to close the Loading Combination dialog.

M. Analysis and Design

M. To Generate a STAAD.Pro Model

To generate a STAAD.Pro input file from your Building Planner workflow physical model, use the following procedure.

The physical model created using the Building Planner workflow can export an equivalent STAAD.Pro input file for use with the analysis and design capabilities in STAAD.Pro.

Tip: You must perform an analysis using STAAD.Pro in order to perform design in the Building Planner or Advanced Concrete Design workflows.

1. In the 3D Frame workspace, select Analysis > Generate Analysis File.
2. Click OK.

   The Space Frame File Generation dialog opens.
Caution: Do not close the dialog by clicking X as this will result in an invalid STAAD input file.

3. Specify the parameters to use for the STAAD input file:
   a. Select the Settings to use for diaphragms, beams, and columns.
   b. Select the load cases to use, including if the seismic load should be (static) Seismic Coefficient Method or Response Spectrum Method.
   c. Select the Building Type.
      For Irregular buildings, both positive and negative direction load cases are generated.
   d. Select whether to Generate EQ Load Using by Joint Weight or Reference Load.

4. Click Generate.
   A warning message opens to inform you that the existing STAAD.Pro model will be overwritten.

5. Click Yes.
   The STAAD.Pro input file is created and opens in the Analytical Modeling workflow.

You can now make changes to the STAAD.Pro file as necessary. You can perform an analysis by selecting the Run Analysis tool on the Analysis ribbon tab or by pressing <Ctrl+F5>.

### Building Type

This option is used to create appropriate load combinations.

- For **Irregular** buildings, both positive and negative direction load cases are generated.
- For **Regular** buildings, only positive direction load cases are generated.

### Generate EQ Load Using

Specifies that earthquake load are created using either **Reference Load** or by **Joint Weight**.

### Generate

Click generate the STAAD input file and open in Modeling mode.

## M. To Design Slabs

You must have STAAD RCDC installed to perform slab design from the Building Planner mode.

You must perform a successful analysis of the generated STAAD.Pro input file prior to performing design.

1. Select **RCDC > Slab**.  
   STAAD RCDC opens and reads the analysis results for the associated STAAD.Pro input file.
2. In STAAD RCDC, select the slab and perform the design.

   **Tip:** Refer to the STAAD RCDC help for details.

3. Close STAAD RCDC when you have completed the slab designs for the selected building level.

## M. To Design Beams

You must have STAAD RCDC installed to perform beam design from the Building Planner mode.

You must perform a successful analysis of the generated STAAD.Pro input file prior to performing design.

1. Select **RCDC > Beams**.  
   STAAD RCDC opens and reads the analysis results for the associated STAAD.Pro input file.
2. In STAAD RCDC, select the beam and perform the design.

   **Tip:** Refer to the STAAD RCDC help for details.

3. Close STAAD RCDC when you have completed the beam designs for the selected building levels.
M. To Design Columns

You must have STAAD RCDC installed to perform column design from the Building Planner mode.

You must perform a successful analysis of the generated STAAD.Pro input file prior to performing design.

1. Select **RCDC > Columns**.
    STAAD RCDC opens and reads the analysis results for the associated STAAD.Pro input file.
2. In STAAD RCDC, select the column and perform the design.

    **Tip:** Refer to the STAAD RCDC help for details.

3. Close STAAD RCDC when you have completed the column designs.
This section of the help describes the analysis methods, data print commands, and how to perform analysis in STAAD.Pro

A. Types of Analysis

A. To specify a linear elastic analysis

To instruct the program to perform a first-order, linear elastic analysis of the structure, use the following procedure.

1. Either:
   - select the Analysis page
   or
   - on the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group

   The Analysis/Print Commands dialog opens.

2. Select the Perform Analysis tab.
3. Select the Print Option you want to use.
4. Click Add.
   The perform analysis command is added to the input file.

Related Links
- TR.37.1 Linear Elastic Analysis (on page 2796)
- Perform Analysis tab (on page 3065)

A. To specify a P-Delta analysis

To instruct the program to perform a second-order, P-Delta analysis, use the following procedure.

1. Either:
   - select the Analysis page
or

on the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group

The Analysis/Print Commands dialog opens.

2. Select the PDelta Analysis tab.

3. Specify a convergence option:
   type the Number of Iterations to use.

   or

   check the Converge option and then type the maximum number of iterations used to check convergence in the adjacent field, even if convergence has not been achieved

   **Note:** You should not specify a Number of Iterations when the Number of Iterations option is checked.

   You may leave the Converge option unchecked and leave the Number of Iterations as zero to use only a single iteration.

4. (Optional) Check the Use Geometric Stiffness (Kg) option to include stiffening effects of the KG matrix.

   Refer to Notes for Stress Stiffening Matrix (Option 2) (on page 2799) for details on this option.

5. Check the Small Delta option to include effects of member deflection (i.e., P-δ effects).

   This option is recommended. Clear this option to only consider effects of structure drift (i.e., P-Δ effects).

6. Select the Print Option you want to use.

7. Click Add.

   The PDetla Analysis command is added to the input file.

**Related Links**
- G.17.2.1 P-Delta Analysis (on page 2349)
- P Delta Analysis tab (on page 3066)
- TR.37.2 P-Delta Analysis Options (on page 2797)

**A. To specify a direct analysis**

To instruct the program to perform a direct analysis as per AISC 360, use the following procedure.

**Note:** You must have one or more members with Direct Analysis parameters defined in order to use a direct analysis.

This is a non-linear, iterative analysis as the stiffness of the members is dependent upon the forces generated by the load. The analysis will iterate in each step, changing the member characteristics until the maximum change in any τ₀ is less than the tau tolerance (τₜₒ₁). If the maximum change in any τ₀ is less than 100×τₜₒ₁ and the maximum change in any displacement degree of freedom is less than the displacement tolerance (δₜₒ₁); then the solution has converged for this case.

1. Either:

   select the Analysis page
or

on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

![Diagram]

The **Analysis/Print Commands** dialog opens.

2. Select the **Perform Direct Analysis** tab.

3. Select to use either the **LRFD** or **ASD** design method.

4. Type values for both **Tau** and **Displacement** Tolerances.

   **Note:** Leave either field empty to use the default tolerances of 0.01 for Tau and 0.01 inches and 0.01 radians for displacement.

5. Type the **Number of Iterations** to use.

   Leave this field empty (zero) to use the default of one iteration.

6. Select the number of **PDelta Iterations** to perform in the iterative PDelta with small delta analysis procedure with a direct analysis.

   The default value of 15 is recommended.

7. (Optional) Clear the **Reduced EI** option to use the full EI for member section moment and section displacement calculations.

8. (Optional) Clear the **Perform Tau-b Iteration** option prevent the program from iterating $\tau_b$.

9. Select the **Print Option** you want to use.

10. Click **Add**.

    The perform direct analysis command is added to the input file.

**Related Links**

**A. To specify a nonlinear analysis**

To instruct the program to perform a geometric nonlinear analysis of the structure, use the following procedure.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

![Diagram]

   The **Analysis/Print Commands** dialog opens.

2. Select the **Nonlinear Analysis** tab.
3. (Optional) Specify the nonlinear analysis parameters as necessary:
   a. Type a absolute displacement limit for the first analysis step in the ARC field.
   b. Type the maximum number of Iterations to use to achieve equilibrium in the deform position within the specified tolerance value.
   c. Type the Tolerance to use for achieving convergence between two sequential iterations.
   d. Type the number of Load Steps to use for applying load in stages.
   e. Type frequency of Rebuild Steps of the tangent K matrix.
4. Check the KG option to add the geometric stiffness to the stiffness matrix.
5. (Optional) Check the Set Displacement Limit option to specify a target displacement:
   a. Either:
      type a Node number
   or
      click [...] to select a node in the view window
   b. Select a DOF (degree of freedom from the drop-down list).
   c. Type a Target Value distance for the displacement limit.
6. Select the Print Option you want to use.
7. Click Add. The perform nonlinear analysis command is added to the input file.

- Nonlinear Analysis tab (on page 3071)

A. To specify a nonlinear cable analysis

To specify a nonlinear cable analysis using the advanced features in STAAD.Pro, use the following steps.
You must specify at least one member with a nonlinear cable specification.

Note: This feature requires STAAD.Pro V8i (SELECTseries 5) (build 20.07.10) or higher.

1. Either:
   select the Analysis page
   or
   on the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group

The Analysis/Print Commands dialog opens.

2. Select the Perform Cable Analysis tab.
3. Select the **Advanced Cable Analysis** option.
4. (Optional) Set the options for **Use Modified Newton-Raphson** method and **Use Geometric Matrix (Kg)** as needed.
5. (Optional) Type values for the **Steps**, **Eq-Iterations**, and **Eq-tolerance** fields as needed. Default values are assumed for each when not specified.
6. Select the **Print Option** you want to use.
7. Click **Add**.
   The advanced cable analysis command is added to the input file.

**Tip:** You can select to add the cable sag values for a nonlinear cable analysis to the output file in the post-analysis **Analysis/Print Commands** dialog.

**Related Links**
- **Perform Cable Analysis tab** (on page 3067)
- **TR.37.3 Nonlinear Cable Analysis** (on page 2800)
- **Perform Cable Analysis tab** (on page 3067)

**A. To specify an imperfection analysis**

To instruct the program to perform an imperfection analysis, use the following procedure.

This analysis is used when member imperfection specifications are included in the model to define camber or drift.

1. Either:
   - select the **Analysis** page
   - or
   - on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

   The **Analysis/Print Commands** dialog opens.
2. Select the **Perform Imperfection Analysis** tab.
3. Select the **Print Option** you want to use.
4. Click **Add**.
   The perform imperfection analysis command is added to the input file.

**Related Links**
- **G.17.2.4 Imperfection Analysis** (on page 2355)
- **TR.37.9 Imperfection Analysis** (on page 2832)
- **Perform Imperfection Analysis tab** (on page 3073)

**A. To specify buckling analysis**

To instruct the program to perform a buckling analysis on the structure, use the following procedure.
This analysis type is used to calculate the buckling factor for a load case. This is the load case multiplier at which global buckling of the structure would occur for that load case.

1. Either:
   
   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group

The **Analysis/Print Commands** dialog opens.

2. Select the **Perform Buckling Analysis** tab.

3. Select the method for the buckling analysis:

   - Iterative method

   or

   - Eigen method - available for STAAD.Pro Advanced only

4. (Optional) If the iterative method is used, type the maximum **Number of Iterations** to use in the analysis.

   It not specified (i.e., left as zero), 20 iterations are used as the default value. 15 is recommended.

   **Note**: MAXSTEPS input is ignored when using the eigen method.

5. Select the **Print Option** you want to use.

6. Click **Add**.

   The perform buckling analysis command is added to the input file.

**Related Links**
- **G.17.2.2 Buckling Analysis** (on page 2353)
- **TR.37.4 Buckling Analysis** (on page 2804)
- **Perform Buckling Analysis tab** (on page 3074)

### A. To specify a pushover analysis

To instruct the program to perform a pushover analysis, use the following procedure.

You mush first define pushover data and the pushover loading.

1. Either:

   select the **Analysis** page

   or

   on the **Analysis and Design** ribbon tab, select the **Analysis Commands** tool in the **Analysis Data** group
The Analysis/Print Commands dialog opens.

2. Select the Perform Pushover Analysis tab.

3. Click Add.
   A message dialog opens to confirm you want to add this command.

Once you have successfully performed a pushover analysis, you can review the pushover results in the Postprocessing workflow.

Related Links
- TR.37.7 Pushover Analysis (on page 2819)
- G.17.4 Pushover Analysis (on page 2376)
- M. Pushover Loads (on page 861)
- Perform Pushover Analysis tab (on page 3075)

A. To add a change command

To add a change command which is required for performing a subsequent analysis command, use the following procedure.

A change command is only added after an analysis command.

In addition to being used for a new analysis, the change command is used to change the support conditions, active/inactive member status, load conditions, etc. The stiffness matrix being solved will be reset when a change command is used.

1. Either:
   - select the Analysis page
   - or
   - on the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group

   The Analysis/Print Commands dialog opens.

2. Select the Change tab.

3. (Optional) Check the After Current option if you previously selected the analysis command in the input file list within the Analysis - Whole Structure dialog.
   This option allows you to specify specifically where the command is added. Otherwise it will be added to the end of the input file.

4. Click Add.
   The change command is added to the input file.

You can now add an additional analysis command to the input file. A change command with no subsequent analysis command has no effect.

Related Links
- G.19 Multiple Analyses (on page 2401)
- TR.38 Change Specification (on page 2835)
- Change tab (on page 3069)
A. To generate a floor spectrum

To calculate the floor spectra from time history acceleration, use the following procedure.

This procedure should only be used if a time history load case is being solved by the analysis engine.

**Note:** The floor response spectrum command must immediately follow an analysis command. Therefore, it is helpful to select the corresponding analysis command prior to starting this procedure.

**Note:** That analysis can only contain a single time history load case.

This command is used to specify the calculation of floor and/or joint spectra from time history results.

1. Either:
   - select the Analysis page
   - or
   - on the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group

   The Analysis/Print Commands dialog opens.

2. Select the Generate Floor Spectrum tab.

3. For every group and direction that is necessary:
   a. Check one or more global directions in a table row: GX, GY, and GZ.
   b. Type a Title used to identify the spectrum.
   c. Use the drop-down to select the Node Groups which are included in this direction.

   You may include as many directions as needed.

4. (Optional) Type frequency options to use for the spectra (all are optional inputs):
   a. Type the Lowest Frequency (in Hz) to be in the calculated spectrum.
      This should be at least 0.0 Hz.
   b. Type the Highest Frequency (in Hz) to be in the calculated spectrum
   c. Type the number of Frequency Interval to use between the lowest and highest frequency.

5. (Optional) Type up to ten Damping Ratios to use as a ratio.
   (e.g., 3% damping is 0.03)

   One spectrum will be generated for each damping ratio for each global direction requested for each floor defined. The spectrum will be based on these damping ratios. Is not entered, the default of 5% (0.05) damping will be used as a single damping ratio.

6. Check the Relative Acceleration? option if there is ground motion defined and you want the spectra based on the relative acceleration of the floor to the ground acceleration.
   Otherwise, the acceleration is assumed to be an absolute acceleration.

7. (Optional) Select the print parameters as needed (both are optional):
   a. Check the Print Time History Acceleration used? option to include this in the output.
   b. Check the Print Calculated Spectrum? option to include this in the output.

8. Select the Print Option you want to use.
Analysis
A. To specify pre-analysis commands

9. Click Add.

Tip: The After Current option is helpful to make sure this is added immediately following the analysis command if you selected prior to this procedure.

The generate floor spectrum command is added to the input file.

Related Links
• TR.37.10 Floor Spectrum Command (on page 2833)
• TR.37.10 Floor Spectrum Command (on page 2833)
• Generate Floor Spectrum tab (on page 3070)

A. To specify pre-analysis commands

To instruct the program to include model input data in the STAAD output file (.an1), use the following procedure.

1. On the Analysis and Design ribbon tab, select the Pre Analysis Commands tool in the Analysis Data group.

The Pre Analysis Print - Whole Structure dialog opens.

2. Click Define Commands.

The Analysis/Print Commands dialog opens.

3. Select the tab corresponding to the print command you want to add to the output file.

   Problem Statistics
   Joint Coordinates
   Member Information
   Material Properties
   Support Information
   All
   Element Information
   Solid Information
   Member Properties

4. Click Add.

Note: If you selected a portion of the model prior to opening the Analysis/Print Commands dialog, you can click Assign to assign the command to those model objects.

The selected print command is added to the input file.

5. Repeat Steps 3 and 4 to add additional print commands.

6. Click Close.

You must assign most print commands to portions of the model using one of the standard assignment methods.

Related Links
• TR.42 Print Specifications (on page 2840)
**A. To create a load list**

To create an active list of load cases for use with subsequent print and design commands, use the following procedure.

A load list is used to control the loads that are included with following print and design specifications.

*Note:* All load cases are considered by analysis commands. You just a CHANGE command to make changes to the loads considered for analysis.

1. On the **Analysis and Design** ribbon tab, select the **Load List** tool in the **Analysis Data** group.

   The **Load List** dialog opens.

2. Either:
   
   select one or more items in the **Load Cases** list and then click **[>]** to include them in the **Load List**
   
   or
   
   click **[>>]** to include all load cases

   *Tip:* Including all load cases is the same as not using a load list at all.

3. Click **OK**

**Related Links**

- **Load List dialog** (on page 3080)
- **TR.39 Load List Specification** (on page 2836)

**A. To check for soft stories and seismic code irregularities**

To check for soft stories and other seismic code irregularities in rigid diaphragm structures, use the following procedure.

*Note:* Soft story checks and plan irregularities are applicable to structures with rigid floor diaphragm definitions. Refer to **M. To assign nodes to a floor diaphragm** (on page 811).

The **CHECK SOFT STORY** option may added to a **FLOOR DIAPHRAGM** command set to check for soft stories per either IS 1893 2002, IS 1893 2016, or ASCE 7-05 codes. The **CHECK IRREGULARITIES** command may be added to check plan irregularities for the IS 1893 2016 code.

*Tip:* You can check plan and vertical irregularities and structure stiffness per EC8 using the **Earthquake workflow** (on page 2240).

1. On the **Analysis and Design** ribbon tab, select the **Miscellaneous Commands > Floor Diaphragm Options** tool in the **Analysis Data** group.
The **Floor Diaphragm Options** dialog opens.

2. Select the building code for which you want to perform earthquake checks:
   - IS1893 2002
   - IS1893 2016
   - ASCE7-05

3. Check the option **Check Soft Story** to perform this check.

4. (IS 1893 - 2016 only) To check for plan and other vertical irregularities, check the option **Check Irregularities**.
   Horizontal irregularities (torsional and reentrant corners) per Table 5 and vertical irregularities (mass irregularities and irregular modes of oscillation) per Table 6 of IS 1893 2016 can be checked by the program using this command.

5. (Optional) If the base of the structure is not the minimum global Y coordinate defined in the structure, then check the **Base Level** option and then type the height of the structure base in the adjacent field.

6. Click **Add**.

**Note:** Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command `PRINT STORY STIFFNESS` in the post analysis print commands section.

**Related Links**

- **TR.28.2.1 Soft Story Checking** (on page 2529)
- **Floor Diaphragm Options dialog** (on page 3079)
A. To specify post-analysis print commands

To include additional analysis results in the STAAD output (.anl) file, use the following procedure.

**Note:** All output values will be available in the postprocessing workflow, regardless of whether you add them to the output file. Similarly, you can add post-analysis output to a report even if not included in the output file.

1. Select the **Post Analysis Commands** tool in the **Analysis Data** group on the **Analysis and Design** ribbon tab.

   ![Analysis/Print Commands](image)

   The **Analysis/Print Commands** dialog for post-analysis commands opens.

   **Tip:** If the dialog does not immediately open, click **Define Commands** on the **Post Analysis Print - Whole Structure** dialog.

2. Select the tab pertaining to the output you want to add to the output file.

3. Check the **After Current** option to insert the print command following the currently selected command within the **Post Analysis Print - Whole Structure** dialog.
   
   Otherwise, the print command will be added to the end of the STAAD input file.

4. Click **Add**.

   The command is added to the STAAD Input file.

5. (Optional) Repeat steps 2 through 4 to add additional print commands as needed.

6. Click **Close**.

   **Note:** Some print commands require a assignment. These will be marked with question mark (?) in the **Post Analysis Print - Whole Structure** dialog. Use the **Assignment Method** tools to assign these to the appropriate model objects.

**Related Links**

- **Analysis/Print Commands dialog (Post Print)** (on page 3076)
- **TR.42 Print Specifications** (on page 2840)
A. To output the center of rigidity

To instruct the program to include the center of rigidity of each rigid diaphragm in the analysis output, use the following procedure.

The lateral force at each floor, as generated by earthquake and wind loading, acts at the center of rigidity of each floor which is modeled as rigid floor diaphragm. The center of mass of each floor is defined as the mean location of the mass system of each floor. The mass of the floor is assumed to be concentrated at this point when the floor is modeled as rigid diaphragm. The distance between these two is the lever arm for the natural torsion moment for seismic loads when that option is used.

1. Select the Post Analysis Commands tool in the Analysis Data group on the Analysis and Design ribbon tab.

   ![Post Analysis Commands](image)

   The Analysis/Print Commands dialog for post-analysis commands opens.

   **Tip:** If the dialog does not immediately open, click Define Commands on the Post Analysis Print - Whole Structure dialog.

2. Select the Dia CR tab in the Analysis/Print Commands dialog.

3. Check the After Current option to insert the print command following the currently selected command within the Post Analysis Print - Whole Structure dialog.

   Otherwise, the print command will be added to the end of the STAAD input file.

4. Click Add.

   The command is added to the STAAD Input file.

5. Click Close.

**Related Links**

- [TR.42 Print Specifications](on page 2840)

A. To report cable sag from an advanced cable analysis

To include the cable sag in the output from an advanced cable analysis, use the following procedure.

**Tip:** Cable sag is only available for advanced nonlinear analysis. If requested for a standard cable analysis, a warning message will be reported in the output.

An advanced cable analysis can also report the deflected shape of the sag in the cable using the PRINT CABLE SAG command.

1. On the Analysis and Design ribbon tab, select the Post Analysis Commands tool in the Analysis Data group.

   ![Post Analysis Commands](image)
A. To specify post-analysis print commands

1. Select the Post Analysis Print - Whole Structure dialog opens.
2. Click Define Commands in the Post Analysis Print - Whole Structure dialog.
3. Select the Analysis/Print Commands dialog opens.
4. Click Add.
5. Click Add.
6. Enter an Allowable Drift Factor value.
7. This is the drift ratio value as specified by the applicable building code.
8. Check the After Current option to insert the print command following the currently selected command within the Post Analysis Print - Whole Structure dialog.
9. Otherwise, the print command will be added to the end of the STAAD input file.
10. Click Add.

The output of a successful advanced cable analysis will report the cable sag in local XYZ coordinates. Post-analysis print will calculate the actual, nonlinear cable displacements along the length of cable.

A. To check for inter-story drift

To instruct the program to check the drift between adjacent stories against a code-defined ratio, use the following procedure.

Story drift is calculated as the relative horizontal displacement of two adjacent floors in a building. Inter-story drift can also be expressed as some factor times the story height. The allowable factor generally varies from one country code to another and may also vary depending on the type of loading. For example, in IS 1893: 2002 for seismic loading the allowable limit for inter-story drift is 0.004 times the story height whereas in IS 875 for wind loading it is 0.002 times the story height.

The drift at a particular story level in either lateral direction is calculated as the average of all the joint displacements present in that floor level. However if floor diaphragm is present, the drift is calculated at the center of mass (i.e., master joint) of the floor.

Note: Additionally, the story stiffnesses used in calculating story drift or checking soft stories can be added to STAAD.Pro output by including the command PRINT STORY STIFFNESS in the post analysis print commands section.

Note: For dynamic IS 1893: 2002 response spectrum, the story drift check is performed by adding a command line within the load case, rather than in the post-analysis print commands. Refer to TR.32.10.1.6 Response Spectrum Specification per IS: 1893 (Part 1)-2002 (on page 2721) for additional information.
The command is added to the STAAD Input file.

6. Click Close.

A. To perform an analysis in STAAD.Pro

Once you have completed the input file, use the following procedure to perform an analysis and optional design.

The STAAD analysis engine performs analysis and design sequentially with a single click. In order to carry out the design, these design parameters must be specified along with geometry, properties, etc. in the input file (this is referred to as a “batch” design). Also, note that you can change the design code used for design and code check before performing the analysis and design.

The Analytical Modeling and Physical Modeling of the STAAD.Pro user interface are used to prepare the structural input data which is then passed to the STAAD analysis engine for general purpose structural analysis and design.

1. Either:
   - Select the Run Analysis tool in the Analysis group on the Analysis and Design ribbon tab.

or

Press <CTRL+F5>

The STAAD Analysis and Design dialog opens.

During the analysis (and design, if specified), an output file is generated. This file may contain selected input data items, results and error messages. Optional print specifications can be used to include additional information in the output file.

2. Select an option for what action occurs when the dialog is closed:
   - Open the output file
   - go to the post-processing mode
   - remain in the analytical modeling mode

3. Click Done.

4. (Optional) To review the output file is this option was not selected in the STAAD Analysis and Design dialog, either:
   - Select the STAAD Output tool in the Utilities group on the Utilities ribbon tab
Analysis

A. To perform an analysis in STAAD.Pro

or

Select the **View STAAD Output File** tool on the Quick Start toolbar.

This section contains information on designing structural elements, organized by material type.

D. Batch Design versus Interactive Design Workflows

STAAD.Pro has two means by which structural members can be designed.

Batch Design

Using this method, code checks and/or member selection is performed directly by the analysis and design engine when an analysis is performed.

Interactive Design Workflow

Code checks and member selection are performed in post-processing workflow for interactive Concrete Design. This workflow is available in the Workflows panel.

D. Steel Design

D. Available Steel Design Codes

All steel design codes are available using the batch design method in the Analytical Modeling workflow (e.g., via the STAAD input file) where not specifically stated otherwise in the workflow column.

### D. Batch Steel Design Operations

STAAD.Pro contains a broad set of facilities for designing structural steel members as individual components of an analyzed structure. The member design facilities provide you with the ability to carry out a number of different design operations. These facilities may be used selectively in accordance with the requirements of the design problem.

The operations to perform a design are:

- Specify the members and the load cases to be considered in the design.
- Specify whether to perform code checking or member selection.
- Specify design parameter values, if different from the default values.

You may repeat these operations any number of times depending upon the design requirements.

For design per American steel codes, STAAD.Pro supports steel design of wide flange, S, M, HP shapes, tees, angle, double angle, channel, double channel, pipes, tubes, beams with cover plate and composite beams (I shapes with concrete slab on top). For other steel design codes, a wide variety of steel shapes are supported.
Refer to the D. Design Codes (on page 1366) for details on the member property specifications and supported steel shapes for design for other codes.

D. To specify steel design code and parameters

To initiate the design of steel members and specify the code parameters, use the following procedure.

Note: To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

2. In Steel Design - Whole Structure dialog, select the applicable steel design code from the Current Code drop-down list.
3. Click Define Parameters. The Design Parameters dialog opens.
4. Specify a value or option for each required parameter for a set of members and then click Add. You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

Note: Different parameters can be used for different member type designs (e.g., columns, beams, composite floor girders, braces, etc.). Alternatively, you can use a separate set of parameters for different member types.

5. Click Close. The design parameters are marked with an icon. This indicates that the need to be assigned to members.

6. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

- Steel Design - Whole Structure dialog (on page 3081)
- Design Parameters dialog (on page 3083)
- TR.48.1 Parameter Specifications (on page 2851)

D. To design steel members in groups

To design members as a group, use the following procedure.

In many situations, it is preferable to have only a few different member sizes for many members rather than each member size be different, even if this would result in some members being underutilized. You can group members in the batch design to instruct the program to replace the member sizes in the group with the highest capacity member of the existing sizes in that group. You can also instruct the program to use a specified section property for the grouping or even group based on a specific member number, regardless of property specifications.

For example, in a floor bay with 5 beam members the edge members were selected as W12x14 shapes and the interior members were selected as W14x22 shapes. Grouping these members will immediately instruct the program to use W14x22 for all members for any subsequent instructions (i.e., analysis, design, take-off, etc.).
Note: All members within a group must be of the same cross section type. If one or more of the members has a different cross-section type, the grouping is ignored by the program.

1. On the Steel Design - Whole Structure dialog, click Commands.
   The Design Commands dialog opens. The tabs (if any) available in this dialog are dependant on the current design code selection. Not all commands are available for every design code.

2. If you want to retain the member groups for all subsequent commands, select the FIXED GROUP tab and then click Add.
   If you do not use the FIXED GROUP option, then the members are grouped once and then this grouping is ignored for subsequent commands. If you do add the FIXED GROUP command, then all subsequent member selection commands will apply to the group again.

3. Select the GROUP tab.

4. (Optional) Select the Property Specification to use for grouping shapes.

5. (Optional) Check the Same as Beam # option and then select a member number from the drop-down list.

6. Click Add.

7. Click Close.

8. Assign the group command to all the members you want to group together.

You can repeat this procedure to create as many design groups as necessary.

Once you have created a group, you will typically want to perform a code check or member selection on the members.

- Design Commands dialog (on page 3084)
- Steel Design - Whole Structure dialog (on page 3081)
- TR.50 Group Specification (on page 2855)

D. To specify steel design commands

To specify the code checking or design commands to be used for the steel design operation, use the following procedure.

1. On the Steel Design - Whole Structure dialog, click Commands.
   The Design Commands dialog opens. The tabs (if any) available in this dialog are dependant on the current design code selection. Not all commands are available for every design code.

2. To perform a design action, select one of the following options (as they are available for the code selection):
   - To... Set...
     - check the capacity of the current member sizes the CHECK CODE tab
     - select a member size based on the last analysis results the SELECT tab
     - select a member size based on iterating the analysis for updated member sizes the SELECT OPTIMIZED tab

3. Click Add.

4. Click Close.

5. Assign the design commands to the appropriate members.

Related Links

STAAD.Pro 952 User Manual
D. To generate steel take off

To generate a summary of all steel sections with their lengths and weights for the whole structure or a list of members, use the following procedure.

1. On the Steel Design - Whole Structure dialog, click Commands.
   The Design Commands dialog opens. The tabs (if any) available in this dialog are dependant on the current design code selection. Not all commands are available for every design code.
2. Select the take off table you want to include:
   
   To... | Select...
   --- | ---
   generate a list of sections used including total length and weight | the TAKE OFF tab
   generate a list sorted by members including the length and weight of the member and section used | the MEMBER TAKE OFF tab

3. Click Add.
4. Click Close.
5. Assign the take off commands to members or to a named group of members.

D. Steel Connection Design

D. Connection Design workflow

D. Getting Started

The following concepts will help you understand how to use Connection Design in STAAD.Pro for the design of steel connections in your engineering practice.

D. Overview

Purpose

The Connection Design mode in STAAD.Pro is used to dynamically link structural model data —including section properties and analysis results— to the Connection Design application in order to check connection designs for code compliance. The resulting data and diagrams of the connection can also be included in the User Report.
**Note:** Not all options described here will be available for versions of Connection Design prior to release 7.0.

**Note:** Full use of the Connection Design mode in STAAD.Pro requires a valid RAM Connection license. The RAM Connection mode will run with a limited set of steel connections available with only a standard STAAD.Pro license. Please contact your Bentley account manager to have a Connection Design license added to your SELECT licenses.

**Description**

Connections are designed in the Connection Design Mode by creating "Joints" from the geometry and section properties. Forces resulting from the analysis are used in this mode by assigning a load envelope. A set of connection templates is then assigned to the joint. A suitable connection design, if one is available, will be reported once you have selected the appropriate connection templates.

Any number of joints may be selected and designed. Further, connection design is performed automatically for you once appropriate templates have been selected for the selected joints. These enhancements greatly reduce the time required for connection design in models of all sizes.

**Tip:** The selected load envelope is now used for all connection designs, instead of per design brief as in previous versions of STAAD.Pro.

Refer to the following procedures and interface elements used in designing steel connections with RAM Connection within STAAD.Pro. For specific information regarding RAM Connection templates, refer to the documentation with RAM Connection.

**D. Full vs. Free Connection Sets**

Basic connection templates are available to users with a valid STAAD.Pro license. The following connections templates are available when using a standard STAAD.Pro license.

- Basic DA BCF Bolted
- Basic DA BCF Welded
- Basic EP BCF Bolted
- Basic EP BCF Welded
- Basic DA BCW Welded
- Basic EP BCW Welded
- Basic SP BCF
- Basic SP BCW

**Note:** In order to use all connection templates (including Smart and Gusset connections), a valid RAM Connection license is required.

For a detailed explanation of connections available, refer to AD.2007-1001.5.1 in the What's New section.

</table>
D. Using the RAM Connection mode

This section provides you with some common procedures used in design steel connections in the Connection Design mode.

D. To edit the RAM Connection settings

1. Click the RAM Settings tool. The RAM Connection Settings dialog opens.
2. Select the default Design Code from the drop down list.
3. (Optional) For AISC codes, select the Consider AISC 341-05 and AISC 358-05 Seismic Provision option to include these seismic checks in design of connections by default for AISC codes.
4. (Optional) Select the Design multiple selected connections individually option to disable grouping of connections into same templates.
5. Check the country names to include various section catalogs in the Sections Add to RAM list.
6. Click OK to save the changes.

Related Links
- D. RAM Connection Settings dialog (on page 977)
- D. RAM Connection Settings dialog (on page 977)

D. To design steel connections

Before performing a connection design, you should select the appropriate design code and options in the RAM Connection Settings dialog.

1. Run an analysis.
Tip: The Connection Design workflow is only available after the completion of a successful analysis.

2. Select **Connection Design** in the Workflows panel.

The **RAM Connection Validation** dialog opens.

3. Click **Close**.

The **RAM Connection Input** dialog opens.

4. Select the **Add Load Envelope** tool.

The **Design Load Envelope** dialog (on page 976) opens.

5. Select the loads you wish to use for design and then click **OK**.

6. Select the joint(s) you wish to add connections to.

   **Note:** Use the selection tools on the **Connection Design** ribbon tab in the **Assign Connections** group to assist selecting the intended joints.

   Selected joints are highlighted with red dots.

7. In the **Connection Design** ribbon tab in the **Assign Connections** group, select the appropriate tool corresponding to the connection assignment you want to make:

   - **Basic Connection** (on page 967)
     
   or

   - **Smart Connection** (on page 968)
     
   or

   - **Gusset Connection** (on page 968)
     
     In the corresponding Connection dialog, you can select which design code and the connection template you wish to use for the selected joint's design brief.

8. Click **OK** to assign the templates and design the connections.

   The Connection Design dialog will display a list of all connection assignments.

9. Click **Close** to dismiss the dialog.

   A list of connections and basic information is displayed in the **RAM Connection Input** table (on page 974).

D. To select a basic connection template

An appropriate set of joints must be selected in order to assign basic connections.

1. Either:

   - on the **Connection Design** ribbon tab, select the **Basic Connection** tool in the **Assign Connection** group

   or
in the **RAM Connection Input** dialog, select the **Basic Connections** tool. The **Basic Connection** dialog opens.

2. You may specify design code or grouping overrides here.

3. Select a connection class from the drop-down list.
   All available connections are displayed in the **Available** list box below.

4. Select one or more connections and add them to the **Selected** list box by clicking the [>] (add) button.

   **Tip:** You may add all connections in the list by clicking the [>>] (add all) button.

5. Click **OK** to accept and design the selected joints using these connections.

**Related Links**

- **Basic Connections dialog** (on page 3166)

**D. To Select a Smart Connection Template**

An appropriate set of joints must be selected in order to assign smart connections.

1. Either:

   Click the **Smart Connections** tool

   or

   Select **Connection Design > Assign Smart Connection**
   The **Smart Connection** dialog (on page 3169) opens.

2. You may specify design code or grouping overrides here.

3. (Optional) For AISC codes, select the option for **Consider AISC 341-05 Seismic Provisions**
   Select a load cases from the drop-down list which represents the gravity load.

4. (Optional) For BS5950 code, select the option to **Consider Structural Integrity** if necessary.

5. (Optional) For Base Plates, select a **Seismic Category** site class from the drop down list.

6. Select a connection class from the drop-down list.
   All available connections are displayed in the **Available** list box below.

7. Select the connection you wish to use and add it to the Selected list box by clicking the Add (>) button.

8. Click **OK** to accept and design the selected joints using these connections.

**Related Links**

- **Smart Connections** (on page 3169)

**D. To Select a Gusset Connection Template**

An appropriate set of joints must be selected in order to assign gusset connections.

1. Either:

   Click the **Gusset Connections** tool

   or
Select **Connection Design** > **Assign Gusset Connection**

The [Gusset Connection dialog](on page 3171) opens.

2. You may specify design code or grouping overrides here.

3. Select a connection class from the drop-down list. All available connections are displayed in the **Available** list box below.

4. Select the connection you wish to use and add it to the Selected list box by clicking the Add (>) button.

5. Click **OK** to accept and design the selected joints using these connections.

- [Gusset Connections dialog](on page 3171)

**D. To design an HBBB connection**

To design a horizontal brace-beam-beam gusset connection, use the following procedure.

**HBBB connections apply to joints with the following conditions:**

- no column at the joint
- two perpendicular beams with H section and one brace with an angle section
- beams should be parallel with the ground (X-Z plane when Y is up)
- the brace should be in the same plane with the beams, with the angle between the brace and either beam between 30° and 60°

1. Start the **Connection Design** workflow and select the applicable load envelope.

2. Select a joint that matches the joint requirements.

3. On the **Connection Design** ribbon tab, select the **Gusset Connection** tool in the **Assign Connections** group.

The **Gusset Connection** dialog opens.

4. Select an AISC design code from the **Design Code** drop-down list.

5. Select **Gusset Plate HBBB** from the connection template drop-down list.

6. Double-click the **HBBB_CA** template to add it to the selected list.

7. Click **OK**.

8. Double-click the connection list view to review the connection design. The connection pad opens.

9. (Optional) If the girder and beam have been incorrectly specified, they can be changed:
   - a. On the **Connection Design** ribbon tab, select the **Beam and Girder Identification** tool in the **Frames** group.
   - The **Beam-Girder Identification** dialog opens.
   - b. Check the Swap option for the beam-girder connection you want to switch.
   - c. Click **Switch**.
   - d. Click **OK**.
   - e. Repeat step 8 to open the connection design again.

**D. To design an HCBB connection**

To design a horizontal brace-column-beam gusset connection, use the following procedure.

**HCBB connections apply to joints with the following conditions:**
• at least one column with an H section at the joint
• column is vertical (perpendicular to beams)
• two perpendicular beams with H section and one brace with an angle section
• beams should be parallel with the ground (X-Z plane when Y is up)
• the brace should be in the same plane with the beams, with the angle between the brace and either beam between 30° and 60°

1. Start the **Connection Design** workflow and select the applicable load envelope.
2. Select a joint that matches the joint requirements.
3. On the **Connection Design** ribbon tab, select the **Gusset Connection** tool in the **Assign Connections** group.

   The **Gusset Connection** dialog opens.

4. Select an AISC design code from the **Design Code** drop-down list.
5. Select **Gusset Plate HCBB** from the connection template drop-down list.
6. Double-click the **HCBB_CA** template to add it to the selected list.
7. Click **OK**.
8. Double-click the connection list view to review the connection design.

D. To edit steel connections

1. Either:

   On the **Connection Design** ribbon tab, select the **Joint Cursor** tool in the **Assign Connections** group and then double-click on any connection in the View window.

   or

   Select the entry for the connection row in the **RAM Connection Input** table and then click **Edit**

   The **Connection Pad** opens displaying the design information for this joint.

2. Make the desired changes to the connection input data.
3. Select the **Save** tool to save any changes.

Changes made to the connection pad are saved back to the connection design in STAAD.Pro.
4. Click the [X] to close the Connection Pad window.

D. Selecting Joints & Connections

The Select Nodes tool is used to select nodes in the View window for assigning connection templates.

The Select Joints tool (found in the Selection toolbar or from the Select menu) is used to select connections in the View window. Typical STAAD.Pro graphical selection rules apply.

The Select menu contains tools to select different connections and joints based on logical criteria:

- The Select > Select Joints sub-menu contains tools which logically select joints based on the connecting members.
- The Select > Select Connections sub-menu contains tools which aide in selecting joints for grouping.

D. Design Connections Individually

Any time multiple connections fitting the same template are selected and a template is applied, these will be grouped to the template meeting the minimum requirement of the entire group.

If you wish to design each connection to an optimized (and likely different) template, then select the Design Connections Individually option in the Connection assignment dialog before clicking OK.

This option can be selected in the RAM Connection Settings dialog (on page 977) to disable the grouping feature.

Related Links

- Basic Connections dialog (on page 3166)

- Smart Connections (on page 3169)

D. To delete steel connections

1. Select the connection(s) you wish to remove in the RAM Connection Input table.
2. Either:
   - press <Delete>
   - or
   - click Delete
3. Click Yes to confirm the deletion.

Tip: You may need to Refresh the display (press <F5>) to see the connection icon removed in the View window.

D. To Export Connection Designs to a Report

To export the connection design results to a Microsoft® Office Word® document report, use the following procedure.

You must perform connection design on one or more connections to generate a report.

1. Either:
On the **RAM Connection Input** Table, select the **Export Connection Reports** tool

or

Select **Connection Design > Export Connections report**.

The **RAM Report Export** dialog opens.

2. Select the connections you want to include in the report.

   **Tip:** Click **Select All** to quickly include all connection design into the report.

3. (Optional) Select or clear options to include **Data Report** Result Report forumla

4. Select to output multiple connections to either **Individual Reports** (separate file for each connection) or a **Merged Report** (single file containing all selected connections).

5. Click **OK**.

The report is generated and saved in the same folder as the STAAD.Pro input file.

**Related Links**
- **RAM Report Export dialog** (on page 3175)

**D. To add connection designs to your report**

To add a summary of steel connection design results to your STAAD.Pro report, use the following procedure.

1. Select the **Postprocessing** workflow.

2. Either:
   - select the **Reports** page
   - select the **File** ribbon tab and then select **Report > Setup** in the backstage view

      The **Report Setup** dialog opens.

3. Select the **Items** tab.

4. In the **Available** topics drop-down list, select **RAM Connection Summary Report**.

5. Double-click the **RCNX Report** entry to add it to the **Selected** list.

      The connection design summary is now included in the report.

6. Either:
   - click **Print** to generate a copy of the report
   - click **OK** to dismiss the dialog and review the report on screen.

**D. Custom Connection Templates**

You can create and use your own connection templates.

**D. To create a custom template file**

Custom template files are created in the **Connection Design** workflow.

1. On the **Connection Design** ribbon tab, select the **Connection Database** tool in the **Configure** group.

      The connection database dialog opens.
2. Click **New group**.
3. Type a New group name then click the X to close the dialog.
   The new group is created and selected as the current group.
4. Click **New table**.
   The new table dialog opens.
5. Specify the table parameters:
   a. Select the **Design code** to use for these connections.
   b. Select the **Connector type** from the drop-down list.
   c. Select the **Joint type** for the connections.
   d. Select the **Connector name** for the connection.
   e. The context-sensitive help panel provides additional information on the connector name selection.
   f. Click **OK**.

   ![New connection dialog](image)

   The new table is saved to the custom group.
6. (Optional) Repeat Steps 4 and 5 to create additional tables as needed.

D. To add a connection template to a table
To add a custom connection template to a database table, use the following procedure.
Tip: One of the simplest methods to get started is to copy factory installed templates to your new group and edit those to suite your needs.

1. On the Connection Design ribbon tab, select the Connection Database tool in the Configure group. The connection database dialog opens.
2. Select Custom in the Groups drop-down list.
3. Click New Item. The Connection Pad window opens.
4. Specify the connection parameters:
   a. Type the connection Name.
   b. Update the connection parameters for this connection type.
   c. Click Save.
   d. Close the window.
   The new connection name is added to the items list. A list of the connection tables where you can add this connection type are also listed.
5. Click >> to add the new connection to the connection database file.

The new connection type is available for use in design in this connection database.

**Note:** When the connection database is selected in the connection database dialog, you can click Reset to remove any custom items and restore the database to the default values.

D. Pages in the Connection Design workflow

The page control bar in Connection Design workflow contains the following pages:

**D. Connections page**

Used to select, assign, design, and edit steel connections. The Connection page is where connections are defined and designed.

When the Connections page is selected, the RAM Connection Input table opens.

The Whole Structure view window displays the structure (or a portion thereof), which is used to graphically select joints for connection assignment and connections for editing.

**Tip:** When a table row(s) is selected in the RAM Connection Input table, the corresponding Joint(s) will be highlighted in the view window.

**D. RAM Connection Input table**

Contains tools to generate new connection designs and contains all previously designed connections.

Opens when the Connection | Connection page (on page 974) is selected.

</table>

**Table**

Once a Connection is established the following information will be displayed in the Input grid:

- Connection Name
- Template used for the Connection
- Description of the Connector
- Node (where the joint is created)
- Members which participated in the connection

**D. Design Load Envelope** dialog

Used to specify the loads which will be included in the Load Envelope used for steel connection design.

Opens when **Connection Design > Load Envelope for Connection** is selected.
Defined Envelopes
Select this option to use a load envelope which has been previously defined for this model. A list of all defined envelopes is then available in the drop-down list. The option will be inactive if no load envelopes have been defined.

Defined Loads
This option allows you to select loads or load combinations to be included in the connection design load envelope. The following tools are used to specify which loads should be included in the envelope.

- **Select All Load Cases Show Below** — Selecting this will select all loads displayed in the load list box.
- **Show Combinations Only** — Selecting this option will limit the load list to load combinations.
- **Load List** — A list of all loads in the model are displayed here. Each load in the list has an associated box to select it for inclusion in the load envelope.

**OK**
Click this button to accept changes made to the Design Load envelope.

**Cancel**
Click this button to close the dialog with no changes saved.

**Help**
This button opens the online documentation.

### D. RAM Connection Settings dialog
Used to set the default design code and grouping toggle.

Opens when the **RAM Settings** tool is selected in the RAM Connection input dialog.
Specify the default design code to be used from the drop-down list. The following codes are currently available in Connection Design in STAAD.Pro:

- AISC 360-10 (ASD) — Allowable Stress Design per AISC 360-10
- AISC 360-10 (LRFD) — Load Resistance Factor Design per AISC 360-10
- AISC 360-05 (ASD) — Allowable Stress Design per AISC 360-05
- AISC 360-05 (LRFD) — Load Resistance Factor Design per AISC 360-05
- AS 4100 1998
- BS 5950-01:2000
- EN 1993-1-7 — Eurocode 3
- IS 800-2007
- GB50017-2003 — "Design of Steel Structures" Chinese code

Consider AISC 341-05 and AISC 358-05 Seismic Provision

(AISC codes only) Select this option to direct the program to consider seismic provisions per AISC 341-05 “Seismic Provisions for Structural Steel Buildings” and AISC 358-05 “Prequalified Connections for Special and Intermediate Steel Moment Frames for Seismic Applications” in the design of connections of members in a designated seismic frame.

Design multiple selected connections individually

Select this option to disable grouping of connections into same templates.

Sections Add to RAM

Check the boxes associated with country section catalog to include in the RAM Connection catalog.

OK

Accepts the settings changes and closes the dialog.

Cancel

Closes the dialog without saving changes.

Help

Opens the Help window.

Related Links

- D. To edit the RAM Connection settings (on page 966)
- D. To edit the RAM Connection settings (on page 966)

D. Results page

Used to review steel connection designs. The Results page displays the summary, layout, and results of the connection designs.

View Window

When a row of a RAM Connection Result table is selected, the DXF drawing and the Report will be displayed in the View window.

RAM Connection Results table

Contains the following items for each connection (upon successful connection design):

- Joint Name
- Template
Design
D. Steel Design

- Design Code
- Ratio (Critical Strength Ratio)
- Status — Possible values:
  - OK (Critical Strength Value < 1),
  - No Good (Critical Strength Value > 1), or
  - Warning (This connection may require additional review)

D. Seismic Frames page

Used to assign and review seismic frames for connection design.

When the Seismic Frame page is selected in the Connection workflow, the RAM Connection Result frames table opens.

D. RAM Connection Result frames table

Used to review frame member assignments and specify reduced section (induced plastic hinge) parameters for beam members within a frame.

Note: A column member may be used in multiple frames but a beam member can only be used in a single frame definition.

Opens when the Seismic Frame page (on page 979) is selected in the Connection workflow.

![RAM Connection Result frames table]

The table rows are grouped first by Frame No and then by Member number. The Type of lateral seismic resisting is also displayed. These elements (shaded in yellow) may not be edited. The location and dimensions of reduced beam sections (RBS) for forming plastic hinges may be specified here for beam members.

Where:

- \( Sh \) is the distance to the Hinge Location
- \( RBS-a \) is the horizontal distance to locate the reduce beam section
- \( RBS-b \) is the length of the reduced section of the flange of the beam
- \( RBS-c \) is the depth of the reduced section of the flange

D. Application Window Layout

After entering the Connection Design Mode is entered, some of the menus change to offer some additional tools.

Note: For help with all other application window elements, please refer to the Modeling mode section of the User Interface help (on page 639).
D. RAM Connection pad

Used to inspect connection details, edit a connections input, and access steel connection design results. Opens when a connection icon is double clicked in the View window.

**Note:** The appearance and layout of the Connection pad varies depending on which version of RAM Connection is installed. The tools and operation remain essentially the same.

The connection pad is required for the creation of templates for the database and also to review/edit a model connection, or many model connections with the connections detailer. It is accessed when any template of the database is edited, when the user double clicks a model connection, or when several identical model connections are selected and the detailing command is invoked from the main menu.

D. Save Graphic dialog

Used to save a connection drawing to an external image file.

Opens when the **Print to File** tool is selected in the **Connection Pad Drawing** window.
**File name**  
Specify a name for the image file.

**Browse**  
Opens a Windows Save As dialog, which is used to specify a drive, directory, and file name for the image file.

**Format**  
Select one of the following common image file formats:

- **Windows Bitmap (BMP)** - An uncompressed image file format. These are very common and readable by most image editing tools. Many word processing or spreadsheet programs can import these image files for re-use. These files can be very large for even relatively short reports (approximately 20x the size of a JPEG).

- **JPEG graphic (JPG)** - A compressed image format commonly used for photographic images. These are also readable by a wide variety of programs, including web browsers, image editors, and office programs. JPEG is not recommended for line drawings or text due to the blurring that may result from its compression algorithm.

**Scale**  
Specify a scale factor to be used with the image file.

**Width**  
Specify a width (in pixels) for the image file.

**Height**  
Specify a height (in pixels) for the image file.

**Block aspect ratio**  
Selecting this option will scale the height or width such that the aspect ratio of the original drawing is constant in the image file.

**OK**  
Create the image file with the selected options and close the Save Graphic dialog.

**Cancel**  
Close the dialog without saving an image file.
D. Connection Tags

Connection tags are used to associate connection data included in an XML file with members. This data can be exchanged with other programs via the ISM link. The connections can also be checked by defined capacities in the XML file.

Connection tags consist of two pieces of data:

i. A Connection Tags XML file, which contains the connection categories, tag names, and member end releases for the connection tag. Connection capacities are also specified for each combination of member and connecting member which may utilize a connection tag. Refer to Connection Tags XML File Schema (on page 986) for additional information on the required structure of this XML file.

ii. Assignments of connection tags to members are stored in the STAAD input file. Though this is done within the DEFINE MEMBER ATTRIBUTE command, it is strongly recommended that the user interface features be used to make connection tag assignments as these must utilize only the connection categories and tag names in the associated XML file. Refer to TR.29.2 Connection Tag Member Attribute (on page 2537) for additional information on this command.

D. To create a connection tag

To create a new connection tag for use in the current STAAD model, use the following steps.

Note: You must have a Connection Tags XML file containing appropriate connection capacities with members used in the model. A default XML file is included with the program that contains a minimal amount of connection data.

A connection tag is added to the model to define the type of connection (e.g., shear or moment) and the associate attributes of that connection (e.g., end releases or capacities associated with the connection).

1. Select one or more members in the view window.
2. Either:
   - on the Beam Tools ribbon tab, select the Assign tool in the Connection Tags group

   or

   - right-click and select Connection Tags > Assign Connection Tags from the pop-up menu

   Note: If you have not specified a Connection Tags XML data file, then the Select Connection Tag File dialog opens prompting you to select an appropriate XML file.

   The Assign Connection Tags dialog and New Connection Tag dialog open.

3. If the New Connection Tag dialog did not already open, then click the New tool in the dialog toolbar.
4. On the New Connection Tag dialog, select the category to use from the Select Categories drop-down list.
5. Select the Tag to use from the selected category from the Select Tags drop-down list.
6. Either:
   - set the option to Assign Beam End Releases to the use the end releases in the connection tag definition
or clear the Assign Beam End Release option and manually select the end releases you want for this connection.

7. Select either the Start or End Location option (or both).

**Note:** Selecting both Start and End locations creates two distinct connections, which must both be assigned.

8. Either:
   - click Add to add this connection to the connection tags list in the Assign Connection Tags dialog
   - or
   - click Assign to assign the connection tag to the current member selection

**Related Links**
- Assign Connection Tags dialog (on page 3183)
- New Connection Tag dialog (on page 3185)

### D. To delete a connection tag

To remove a connection tag entirely from the STAAD model, use the following steps.

This procedure will remove the connection from the model. To remove the assignment of a connection tag from one or more members, see D. To remove connection tag assignments (on page 984).

1. Select one or more members in the view window.
2. Either:
   - on the Beam Tools ribbon tab, select the View tool in the Connection Tags group
   - or
   - on the Utilities ribbon tab, select the Connection Tags > View Tags tool in the Tools group
   - or
   - right-click and select Connection Tags > View Connection Tags from the pop-up menu.
   - The Assign Connection Tags dialog opens.
3. Select the row in the Connection Tags table for the connection tag you want to remove.
4. Select the Remove tool in the dialog toolbar.
   - A confirmation dialog opens to confirm you want to delete the connection tag.
5. Click OK.
   - A confirmation dialog opens in the STAAD.Pro user interface window to confirm you want remove the associated STAAD input command for the member attribute definition.
6. Click Yes.
   - The row is removed from the Connection Tags table.
D. To remove connection tag assignments

To remove the connection tag assignments from members, use the following steps.

This procedure will disassociate a connection tag with a member end. If you want to complete remove a connection tag from the STAAD.Pro model, see D. To delete a connection tag (on page 983).

1. Select one or more members in the view window.
2. Either:
   - on the **Beam Tools** ribbon tab, select the **Remove** tool in the **Connection Tags** group
   - right-click and select **Connection Tags** > **Remove Connection Tags** from the pop-up menu

The **Assign Connection Tags** and the **Remove Connection Tag** dialogs open.

3. Select either the **Start** or **End** (or both) corresponding to the member end from which you want the connection tag removed.
4. (Optional) If you do not want the beam end releases for this beam end changed, then clear the option **Remove Beam End Releases**.

   **Tip:** By default, this option is set so the member end releases for this end are returned to their defaults (i.e., fully fixed).

5. Click **Remove**.
   A confirmation dialog opens.
6. Click **OK**.
   A confirmation dialog opens in the STAAD.Pro user interface window to confirm you want remove the associated STAAD input command for the member attribute definition.
7. Click **Yes**.
   The member number is removed from the Assigned Beams cell of the Connection Tags table.

   **Note:** If the tag selected was only assigned to a single member end, then the row is removed from the Connection Tags table.

**Related Links**

- **Remove Connection Tags dialog** (on page 3187)
D. To check connection tags

To check the assigned connection tags capacity using the STAAD.Pro analysis results, use the following steps.

Prior to checking connections, you must perform a successful analysis on the model so analysis results at member ends can be compared to connection capacities.

Additionally, each beam and connecting member (beam or column) must have a connection capacity for the sections used in the associated Connection Tags XML file to facilitate checking connections.

1. Select one or more members in the view window.
2. Either:
   - on the Beam Tools ribbon tab, select the Check tool in the Connection Tags group
   - or
   - on the Utilities ribbon tab, select the Connection Tags > Check Tags in the Tools group
   - or
   - right-click and select Connection Tags > Check Connection Tags from the pop-up menu
   - The Assign Connection Tags dialog and Check Connection Tags dialog open.
3. Select the load case types you want to use in the Select Load Case Types drop-down list. The load cases list displays only the type or types selected.
4. Either:
   - select load cases individually by setting their check boxes on in the list
   - or
   - set the Select All option check box on.
5. Click Check.
   - The Connection Tag Check Results table opens. This table displays the connection tag data from the Connection Tag XML file capacity used checked against the critical load case at each member end with a connection tag. The status of the check (i.e., Pass or Fail) is listed in the Remarks column.

Related Links
- D. Connection Tags Capacity Checks (on page 985)
- Check Connection Tags dialog (on page 3100)

D. Connection Tags Capacity Checks

The rules for checking the connections are dependent on the whether the connection is typed as moment or shear.

**Moment Connections**

Shear Capacity Check - The shear capacity for a given beam/column combination present in the ConnectionTagFile.xml is checked against the demand taken as the absolute value of the major axis shear value, Fy, from each of the load cases included and the maximum value reported.
If the shear capacity in the XML file is 207.345 kN, then:

- when \( F_y = \pm 208.0 \text{ kN} > 207.345 \text{ kN} \), the connection check is failed.
- when \( F_y = \pm 200.0 \text{ kN} < 207.345 \text{ kN} \), the connection check is passed.

**Moment Capacity Check** - The moment capacity check for a given beam/column combination is based on both the major axis moment and axial force. For each load case, the maximum demand is taken from the end moment plus the axial force multiplied by a specified alpha factor and compared against the given moment capacity.

If the moment capacity in the XML file is 35.951 kN·m and the tension force factor, alpha, is 0.09565, then

\[
\text{demand} = |M_z| + \alpha \cdot |F_x|
\]

- when \( M_z = 30 \text{ kN·m} \) and \( F_x = -50 \text{ kN} \), then demand is \( 30 + 0.09565(50) = 34.7825 \text{ kN·m} < 35.951 \text{ kN·mm} \), the connection check is passed.
- when \( M_z = 32 \text{ kN·m} \) and \( F_x = -50 \text{ kN} \), then demand is \( 32 + 0.09565(50) = 36.7825 \text{ kN·m} > 35.951 \text{ kN·mm} \), the connection check is failed.

**Shear Connections**

The shear capacity for a given beam/column combination present in the `ConnectionTagFile.xml` is checked against the demand taken as the major axis shear value, \( F_y \), and a proportion of the axial force, \( F_x \), from each of the load cases included and the maximum value reported.

If the shear capacity in the XML file is 15.538 kN and the tension force factor, alpha, is 0.2016, then demand = \( |F_y| + \alpha \cdot |F_x|\):

- when \( F_y = 12 \text{ kN} \) and \( F_x = -25 \text{ kN} \), then demand = \( 12 + 0.2016(25) = 17.04 \text{ kN} > 15.538 \text{ kN} \), the connection is failed.
- when \( F_y = 10 \text{ kN} \) and \( F_x = 25 \text{ kN} \), then demand = \( 10 + 0.2016(25) = 15.04 \text{ kN} < 15.538 \text{ kN} \), the connection is passed.

Note: There are no moment capacity checks for a shear connection.

**Related Links**

- [D. To check connection tags](on page 985)
- [Check Connection Tags dialog](on page 3100)

**D. Connection Tags XML File Schema**

A simple schema is used to define the data for a Connection Tags XML file used for storing connection tag data for STAAD.Pro.

When you initiate a connection tags action for the first time from the right-click pop-up menu, you will be prompted to select a Connection Tags XML file for use with creating and checking connection tags.
ConnectionTagFile

The `<ConnectionTagFile>` element is the root element for a STAAD.Pro Connection Tags file. Within a ConnectionTagFile element two types of data: connection categories and connection tags.

Table 54: ConnectionTagFile model details

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Contained by</td>
<td>ConnectionTagFile</td>
</tr>
<tr>
<td>Attributes</td>
<td>value (required, decimal)</td>
</tr>
</tbody>
</table>

Categories

The `<Categories>` element contains individual connection categories. Typically a connection tags file contains both Moment and Shear categories.

Table 56: Categories model details

<table>
<thead>
<tr>
<th>Contains</th>
<th>(Category) (one or more)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>ConnectionTagFile</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
</tr>
</tbody>
</table>

Category

The `<Category>` element defines a connection category.

Table 57: Category model details

<table>
<thead>
<tr>
<th>Contains</th>
<th>(CategoryDesc)</th>
</tr>
</thead>
</table>
**CategoryDesc**

The `<CategoryDesc>` element is used to provide a human readable description for the parent connection category. It can contain any alpha-numeric string.

**Table 58: CategoryDesc model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>text data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Category</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
</tr>
</tbody>
</table>

**Equations**

The `<Equations>` element contains individual equations.

**Table 59: Categories model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>(Equation) (one or more)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>ConnectionTagFile</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
</tr>
</tbody>
</table>

**Equation**

The `<Equation>` element contains a user-defined equation.

**Table 60: Capacity model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>n/a (empty element)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Equations</td>
</tr>
</tbody>

Attributes

<table>
<thead>
<tr>
<th>Attributes</th>
<th>EquationID (required, string), Equation (required, string), Condition (required, string), Limit(required, decimal)</th>
</tr>
</thead>
</table>

See “Equations Guidelines” (on page 993) for details on writing equation and condition values.

Tags

The `<Tags>` element contains the connection tag data in a series of child elements.

**Table 61: Tags model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>(Tag) (one or more)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>ConnectionTagFile</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attributes</th>
<th></th>
</tr>
</thead>
</table>

Tag

The `<Tag>` element contains an end release definition and a set of connection capacities to be used for checking connection tags.

**Table 62: Tag model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>(EndRelease then Capacities)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Tags</td>
</tr>
<tr>
<td>Attributes</td>
<td>TagName (required, string, no default), CategoryName (required, restricted string data, no default); values are: MOMENT SHEAR</td>
</tr>
</tbody>
</table>

EndRelease

The `<Tag>` element is used to specify the end release conditions to be used with a connection tag.

**Table 63: EndRelease model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>n/a (empty element)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Tag</td>
</tr>
</tbody>
</table>
Attributes

<table>
<thead>
<tr>
<th>Attributes</th>
<th>FX (required, restricted integer), FY (required, restricted integer), FZ (required, restricted integer), MX (required, restricted integer), MY (required, restricted integer), MZ (required, restricted integer)</th>
</tr>
</thead>
</table>
|            | The range for these attributes is:  
|            | 0 - restrained  
|            | 1 - full release |

**Capacities**

The `<Capacities>` element contains one or more connection capacity value sets for a specific system of units.

**Table 64: Capacities model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>(Capacity) <em>(one or more)</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Tag</td>
</tr>
</tbody>
</table>
| Attributes | UnitSystem(required, restricted string data, no default); values are:  
|            | METRIC  
|            | IMPERIAL |

**Beam**

The `<Beam>` element contains one or more beam or column sections.

**Table 65: Beam model details**

<table>
<thead>
<tr>
<th>Contains</th>
<th>BeamOrCol <em>(one or more)</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Capacities</td>
</tr>
<tr>
<td>Attributes</td>
<td>Name (required, string)</td>
</tr>
</tbody>
</table>

**BeamOrCol**

The `<BeamOrCol>` element is used to specify connection capacity bending and shear capacities for a specific member, or for the default member.
Table 66: BeamOrCol model details

<table>
<thead>
<tr>
<th>Contains</th>
<th>n/a (empty element)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Beam</td>
</tr>
<tr>
<td>Attributes</td>
<td>Name (required, string), Mz.cap (required, decimal), Fx.cap (required, decimal), Fz.cap (required, decimal), alpha (required, decimal)</td>
</tr>
<tr>
<td></td>
<td>See D. Connection Tags Capacity Checks (on page 985) for details on how these values are used.</td>
</tr>
<tr>
<td></td>
<td>See “Use of Wild Cards (on page 993)” for details on using defaults.</td>
</tr>
</tbody>
</table>

**Checks**

The `<Checks>` element contains one or more check.

Table 67: Checks model details

<table>
<thead>
<tr>
<th>Contains</th>
<th>(Check) (one or more)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Tag</td>
</tr>
<tr>
<td>Attributes</td>
<td>none</td>
</tr>
</tbody>
</table>

**Check**

The `<Check>` element is used to specify connection capacity between specified members required for checking connections.

Table 68: Check model details

<table>
<thead>
<tr>
<th>Contains</th>
<th>n/a (empty element)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contained by</td>
<td>Checks</td>
</tr>
<tr>
<td>Attributes</td>
<td>Type (required, string), Desc (required, string), EquationID (required, string) - reference to equation IDs.</td>
</tr>
</tbody>
</table>
### Use of Wild Cards

Instead of specifying the capacities and other details for each individual beam or column section, "wild card" entries can be used. This is particularly useful when the remaining attributes are the same for multiple sections.

Example using the Default wild card:

```xml
<Beam Name="UB203x102x23">
  <BeamOrCol Name="Default" Mz.cap="35.9156" Fx.cap="207.3451" Fz.cap="" />
</Beam>
```

### Equations Guidelines

The following table contains the expressions that can be evaluated for user-defined equations:

<table>
<thead>
<tr>
<th>Digits/Characters</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>.</th>
<th>,</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary Operators</td>
<td>+</td>
<td>-</td>
<td>*</td>
<td>/</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Unary Operators</td>
<td>+</td>
<td>-</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parenthesis</td>
<td>(</td>
<td>)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Symbols</td>
<td>PI</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Functions</td>
<td>ABS</td>
<td>POW</td>
<td>ROUND</td>
<td>SQRT</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>MAX</td>
<td>MIN</td>
<td>SIN</td>
<td>COS</td>
<td>TAN</td>
<td>ASIN</td>
<td>ACOS</td>
<td>ATAN</td>
<td>LN</td>
<td>LOG</td>
<td>EXP</td>
<td></td>
</tr>
<tr>
<td>Reserved Keywords</td>
<td>[MZ.CAP]</td>
<td>[FX.CAP]</td>
<td>[FZ.CAP]</td>
<td>[FX]</td>
<td>[FY]</td>
<td>[FZ]</td>
<td>[MX]</td>
<td>[MY]</td>
<td>[MZ]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:
- "," (comma) can only be used with the POW function
- The ROUND function rounds off to the nearest integer, not to a certain decimal place
- Condition attributes should include any one of the following:
  - EQ - equal to
  - LT - less than
- LE - less than or equal to
- GT - greater than
- GE - greater than or equal to
- Reserved keywords should be specified with square brackets
- Reserved keywords, symbols, functions, and conditions are not case sensitive.

Example of an equation:

```
<Equation EquationID="Eq1" Equation="Abs([MZ])/[MZ.CAP]+Abs([FX])/[FX.CAP]"
    Condition="LT" Limit="1.0" />
```

- *D. Batch Design versus Interactive Design Workflows* (on page 944)

**D. Batch Member and Element Design Operations**

How to perform concrete member and slab design in the Analytical Modeling workflow using batch operations.

**D. To specify concrete design code and parameters**

To initiate the design of concrete members and specify the code parameters, use the following procedure.

**Note:** To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the **Analysis and Design** ribbon tab, select **Concrete** in the **Design** group gallery. The **Concrete Design - Whole Structure** dialog opens.
2. In the **Concrete Design - Whole Structure** dialog, select the applicable concrete design code from the **Current Code** drop-down list.

3. Click **Define Parameters**.
   The **Design Parameters** dialog opens.

4. Specify a value or option for each required parameter for a set of members and then click **Add**.
   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

   **Note:** Different parameters can be used for different member type designs (e.g., columns, beams, etc.). Alternatively, you can use a separate set of parameters for different member types.

5. Click **Close**.
   The design parameters are marked with an 📚 icon. This indicates that the need to be assigned to members.

6. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

**D. To specify concrete beam design command**

To specify the design commands for concrete beams, use the following procedure.

1. On the **Concrete Design - Whole Structure** dialog, click **Commands**.
   The **Design Commands** dialog opens.
2. To perform a design action for concrete members, select one of the following options based on the member type:
   
   To... Select...
   
   design members acting as beams the DESIGN BEAM tab
   design members acting as columns the DESIGN COLUMN tab

3. Click Add.
4. Click Close.
5. Assign the design commands to the appropriate members.

Related Links

D. To generate concrete take off

To generate a summary of the total concrete volume along with the reinforcing steel bar numbers and weights for the design concrete members, use the following procedure.

1. On the Concrete Design - Whole Structure dialog, click Commands. The Design Commands dialog opens.
2. Select the **TAKE OFF** tab.
3. Click **Add**.
4. Click **Close**.
5. Assign the take off commands to members or to a named group of members.

**Related Links**

**D. Interactive Concrete Design**

A STAAD.Pro module.

**Note:** Interactive Concrete Design was referred to as "RC Designer" in older versions of STAAD.Pro.

**D. General Overview**

The STAAD.Pro Reinforced Concrete Designer (Concrete Design) is a post processor that works from the STAAD.Pro analysis results. The data is passed into Concrete Design includes the geometry, section and material properties, loads and combination information and analysis results.

For information on other components of the STAAD.Pro environment, refer to separate documentation.
D. Introduction

STAAD.Pro Concrete Design is started by selecting the menu option from STAAD.Pro. When this is done a link file is produced that contains the basic data for creating concrete designs. This data is created each time the program is started. Additional data that is created during the use of the program is stored, such as the members, envelopes, design groups and design briefs is stored in a persistent file. This means that if the program is closed and re-opened at a later date, the data remains available and does not need to be re-entered.

**Note:** At any time the persistent data can be removed by selecting the re-load link option from the File menu.

Related Links

D. Suitable Member Properties

Concrete beam and column designs can only be performed on physical members that have been created from beam elements (not plate or solid elements).

Concrete slab designs can only be performed that have been defined on slabs that have been created from finite element or plate elements.

The type of brief also requires that the beams are created from the following section property commands:

**Beam Design Briefs**

Rectangular or Square sections

<table>
<thead>
<tr>
<th>PRISMATIC</th>
<th>YD</th>
<th>ZD</th>

<td>.sec</td>
<td>Analysis Result File</td>
</tr>
<tr>
<td>.Rei_Concrete</td>
<td>Persistent File</td>
</tr>
<tr>
<td>.Rei_Concrete_Link</td>
<td>Link file</td>
</tr>
</tbody>
</table>

All these files are stored in the same folder as the input file (.std).

The program also makes use of SProRC21.00.00.ini in the
C:\ProgramData\Bentley\Engineering\STAAD.Pro  CONNECT Edition folder. This file contains the user settings for fonts, colors, the current units, the conversion factors for the various unit settings.

**D. Using the Interactive Concrete Design**

This section contains some of the fundamental tasks and concepts used in Concrete Design.

**Tip:** It is also strongly recommended that you work through the example provided (on page 4936) to familiarize yourself with the program.
D. To open model in the interactive concrete design workflow

Concrete Design is a module of STAAD.Pro and as such needs data first created in the STAAD.Pro environment. Therefore to use Concrete Design, first create a suitable model in Analytical Modeling or Physical Modeling workflow in STAAD.Pro. This model includes the geometry, properties, loading, and analysis commands. The model must then be successfully analyzed.

1. In the STAAD.Pro User Interface, select Concrete Design in the Workflows panel.

The STAAD.Pro RC Designer window opens with the current model loaded.

**Note:** Concrete Design cannot be run as an independent application. It must be initiated from within STAAD.Pro.

**Related Links**
- D. Introduction (on page 1006)

D. Load Cases, Combinations, and Envelopes

STAAD.Pro and Concrete Design makes use of primary load cases, load combinations and load envelopes. The designs that are performed in RC Designer can make use of one or more sets of these results, but it is dependent upon the type of Design Brief that is to be used.

**Members Designed using Beam Design Briefs**

These perform designs on a defined envelope of primary load cases and/or load combinations. Currently, the envelope must be defined in the Envelope Page of the Design Layer Mode. The design is performed at a number of sections along each design member to satisfy the maximum positive and negative forces that exist at that section from all the load cases in that envelope.

**Members Designed using Column Design Briefs**

These perform designs on a collection of primary load cases and/or load combinations. Unlike the Beam Design Briefs, the design is done for the forces in each loadcase / combination and a suitable reinforcement layout defined accordingly.

**Floor Slabs Designed using Slab Design Briefs**

These perform designs on a defined envelope of primary load case and/or combinations. The design will report the reinforcement requirements of the maximum positive and negative moments at each location.

D. Design of Members and Slabs

Unlike analysis models which requires models to be broken down into separate analytical components of beam segments and finite elements, the designs in Concrete Design are performed on design members and slabs.

The design members and slabs need to be created in the Concrete Design environment.

Design members can be designed with either Beam or Column Design Briefs.
D. Rules for Forming Members

To form a member, the following rules must be obeyed.

- All elements must form a single continuous line. But they do not have to form a straight line. Thus curved members may be formed.
- There must be a free end. Whilst curved members are allowed, they cannot form a closed loop.
- All elements must have the same beta angle.
- All elements must point in the same direction. Check with the orientation labels if necessary. Use the reverse element command on elements that point the wrong way.
- None of the elements can be part of another member.
- The section properties must be consistent at each element end. Elements can taper along their length, but where one element ends and the next starts, they must have the same section reference.
- All elements must be made from the same material.

D. Creating a design (physical) member

1. Select the Des. Layer | Members mode (on page 1202).
2. Select the Elements Cursor tool (default selection tool).
3. Select the constituent element(s) that will combine to form a design (physical) member

   **Tip:** Hold the <Ctrl> key to select a number of elements.

   **Note:** Refer to D. Rules for Forming Members (on page 1009) for element rules when forming a physical member.

   **Note:** An analytical beam segment can only be part of one design member definition.

4. Select either:
   - Members > Form Member
   - The Form Member tool.

   Information on Design Members can be selected using the Members Cursor. Details of design members can be seen in the Members Table (on page 1151).

D. Deleting a design member

1. Select the Des. Layer | Members mode.
2. Select the Members Cursor tool.
3. Either:
   - Press <Delete>.
   - or
Select **Edit > Delete.**

**D. Rules for Forming Slabs**

To form a slab, the following rules must be obeyed.

- All elements must form a single continuous area.
- None of the elements can be part of another Slab.
- All elements must be made from the same material.

**D. Creating a design slab**

1. Select the **Des. Layer | Slabs page** (on page 1202).
2. Select the **Select Plates** cursor tool.

3. Select the constituent element(s) that combine to form a design slab.

   **Tip:** Hold the <CTRL> key to select a number of elements.

   **Note:** Refer to **D. Rules for Forming Slabs** (on page 1010) for element rules when forming a slab.

   **Note:** A finite element can only be part of one slab definition.

4. Either:
   - Select **Slabs > Form Slab.**
   - The **Form Slabs** tool.

Information on design slabs that have been created is listed in the **Slabs Table** (on page 1153).

**D. Deleting a design slab**

1. Select the **Des. Layer | Slabs mode.**
2. Select the **Select Slabs** tool.
3. Either:
   - Press <Delete>.
   - Select **Edit > Delete.**

**D. Design Briefs**

Designs are performed on design members and design slabs according to a set of rules defined in the appropriate code. A number of the criteria, such as the dimensions of the beams, columns, and slabs have
already been defined in the STAAD.Pro model. However, certain aspects have not, such as the grade of concrete and steel reinforcing bars. All the parameters that are required are collected together and referred to as a Design Brief. Each Design Brief is tailored to the requirements of the governing design code.

Details of contents of each brief can be found in section 4.3.5 (on page 1218).

**Available Codes**

c_design_brief_dialogs (on page 1218) for information on the dialogs for a specific member type and code.

### D. Design Groups

The final stage in preparation is collecting together the design members and slabs into a Design Group. The Design Group contains not only the list of members (or slab number) to be designed, but also which Design Brief that is to be used.

The list of Design Groups can be seen in the Design Groups table (on page 1160). This has separate tabs for Member Groups and Slab Groups.

#### D. Creating a Member Design Group

1. Either:
   - Select the Des. Layer | Groups/Briefs page.
   - or
   - Select Groups > Design Group Table.

   The Design Group table (on page 1160) opens.

2. Select the Members tab on the Design Groups table.
3. Select the members to be included in the design group using the Member Cursor tool.

   **Note:** A design member may be part of more than one design group.

   The New Design Group dialog (on page 1149) opens.

5. (Optional) Specify a name for the Design Group.
6. Select a previously created Design Brief to be used for designing the physical elements in this group.
7. Click OK.
D. Modifying the design members included in a Design Group

1. Select the group number in the Design Groups table.
2. Click on Edit Design Groups at the bottom of the table.
   The Group Member List table (on page 1160) opens.

D. Adding a member to the group

1. Select the last (empty) cell in the table.
2. Enter the member number.
3. Press either the <Tab> or <Enter> key.

D. Adding members to an existing design group

1. Select one or more members in the View window.
2. Right click to display the View window pop-up menu.
3. Select Add member(s) to Design Group...
   The Add Member(s) to Design Group dialog box opens.
4. Select the Design Group to which you want to add the selected members.

   Tip: The current Design Group is selected by default.
5. Click the Add button.
6. Click OK to close the dialog.

D. Removing a member from a group

1. Select the member number in the table.
2. Press <Delete>.

D. Coping a reinforcing cage design for re-use in another column group

Note: If the member has a reinforcement cage already defined, then the program checks the reinforcement for compliance. Otherwise the program will select a reinforcement cage from the bars and specifications of the Design Brief to minimize the area of main reinforcement bars.

1. Select a column member included in the previously designed column group.
2. Select Edit > Copy.
   Reinforcement cage details are copied to the clipboard.
3. Select columns to which you want to assign the reinforcing details.

   Note: Target columns must be of the same dimensions as the source column.
4. Select Edit > Paste.
   The details are copied to the target columns and can then be checked for compliance.

D. Creating a Slab Design Group
1. Select the Slabs tab on the top of the Design Groups Table
2. Click the New Design Slab button.
   The New Design Slab dialog (on page 1162) opens.

3. (Optional) Specify a name the Design Group
4. Select a previously created Slab Design Brief to be use for designing the slab.
5. Select the physical slab number for this Design Slab.
   
   **Note:** Slab design groups only contain a single slab, but this can be divided into separate Regions later.

6. Click OK.

D. Using View Windows

View windows are used to display all or parts of the structural model. Most model object selection is made using the mouse pointer (through various object cursor tools) in the view windows.

Multiple view windows may be open simultaneously. The top view window is referred to as the active view window. Actions which affect view windows are typically applied only to the active view window.

Views are manipulated by the view and zoom tools found on the Standard toolbar (on page 1193) or by the Orientation dialog (on page 1133).

**Tip:** View Windows have context-sensitive pop-up menus. When different items are selected (or even when there is no selection), right-clicking will display commonly used functions for the current selection set.
**D. Creating a new view of a portion of the model**

**Tip:** This feature is useful for manipulating portions of larger structures.

1. Select one or more objects in the active view window.
2. Select View > New View
   - The **New View** dialog opens prompting if you want to replace the current active window or open a new active window.
3. Select a window option and click OK.
   - The new view is opened displaying on the selected model object(s).
D. Saving a view window for later use

You can save a view window which displays <untitled> in the window title bar.

1. Select View > View Management > Save View
   The Save View As dialog (on page 1136) opens.
2. Type a title for the view.
3. Click OK.

D. Reopening a saved view

1. Select View > Open View.
   The Open View dialog (on page 1134) opens.
2. Select a previously saved view from list.
3. Select if the view is re-open in a view window or to replace the active view window.
4. Click OK.
   The view window re-opens and is now the active view window.

Related Links
- D. Open View dialog (on page 1134)

D. Report Setup

The graphical user interface (GUI) will report the summary of a design and display the summary of calculations performed. Each design brief also has its own detailed calculation routines that allow the important details of the calculations to be viewed.

To view the detailed calculations, select the Design Detail for inclusion in the Report Setup dialog (on page 1110).

Note: If the design group has a large number of members, this may produce a very large document. Therefore, you may want to select only a few members for reporting with this option.

Pictures can also be added to a report, including symbolic elevations and sections of the reinforcement.

D. Creating a symbolic picture

1. Click anywhere on the diagram or cross section segments of the reinforcement in a Main Reinforcement Diagram
2. Select the Take Picture tool.
   The Picture Setup dialog box (on page 1016) opens. of the diagram, which can be resized to fit within the print space.

This is added to the available items in the Repost Setup and can be selected and added to the Selected items as with any other print item.

D. Picture Setup dialog
Used to create a reinforcing detail picture for inclusion in reports. The file contains elevations, sections and a bending schedule.
Design
D. Concrete Design

Opens when the **Take Picture** tool is selected for a Main Reinforcing Diagram or a Shear Reinforcement Diagram.

The controls in this dialog are analogous to those in the Export Drawing dialog (on page 1188).

**OK**  
Accepts the changes made and closes the dialog.

**Cancel**  
Closes the dialog without making any changes.

D. Design or Check

Concrete Design can function in one of two ways, either as a Design or as a Check.

The Design Method is the default in which the design process will run through and provide the minimum reinforcement required based on the associated design brief.

The Check Method is available if you change the reinforcement and selects **Design > Design Now**. With this method, the specified reinforcement is checked at all the locations and the status for the overall design member is reported.

**Caution:** This method is only available for designs performed on design groups that have a column design brief.
D. Earthquake Checks

For select design codes, Concrete Design can perform additional earthquake detailing checks per the building code.

D. To Perform a Preliminary Design per EC2 in RC Designer

In order for EC8 checks to be performed, a member must have passed all EC2 checks in the initial design step. To also help identify issues in design or detailing, if one step of checks fails for a member, further checks will not be performed on that member.

The program will first check that all materials in the design brief are satisfactory. Then, moment capacity of beams and columns are evaluated and compared. EC8 stipulates that columns must have a moment capacity of 1.30 times the sum of the moment capacity of beams framing at that joint. This ensures beams are the initial failure mode.

**Note:** Deflection checks are performed for individual members only.

   - The following National Annexes are available in RC Deigner:
     - Singapore National Annex
     - UK National Annex
     - Malaysian National Annex
   - You can also select **EC2 without Annex** and specify the NA parameters manually.

2. Specify Medium (DCM) or High (DCH) in the Ductility level list.
   - Low ductility (DCL) does not require additional Eurocode 8 checks and therefore is not included.

3. Specify the load case containing seismic loads for use with design checks.

4. Specify the Structural Type in the list.
   - Currently, only Framed/ Dual/Coupled Wall Systems are supported in RC Designer.

5. Select if you wish to Check reinforcement for detailing rules for ductility per EC8.

6. Specify a Curvature ductility factor to be used for column checks.
   - If not specified, the default value is taken as unity (1).

7. Click Check Now to perform all design and detailing checks.

**Related Links**
- [P. Using the Earthquake Workflow](on page 2240)

D. To perform seismic design and detailing per EC8

To perform seismic design and detailing checks per Eurocode 8, use the following procedure.

A preliminary design per Eurocode 2 must be made for all concrete members prior to detailing and design per Eurocode 8. In order for EC8 checks to be performed, a member must have passed all EC2 checks in the initial design step.

1. Select the **Earthquake** tab.
   - The **Collapse Check Setup** dialog opens.
2. Select **EC8 - 2004** from the **Design Code** list. Currently, only the UK Annex is available.

3. Select the **Ductility level** of the structure:
   - **DCM** - Medium ductility
   - **DCH** - High ductility
   
   **Note**: Low ductility (DCL) does not require additional Eurocode 8 checks and therefore is not included.

4. Select the **Earthquake load case** containing seismic loads for use with design checks.

5. Specify the **Structural Type** in the list. Refer to the code for descriptions of each type.

6. Check the option to **Check reinforcement detailing rules for ductility** if applicable.

7. Specify a **Curvature ductility factor** to be used for column checks. If not specified, the default value is taken as unity (1).

8. Click **Check Now**. The program performs the design and detailing checks.

To help identify issues in design or detailing, if one step of checks fails for a member, further checks will not be performed on that member.

The program will first check that all materials in the design brief are satisfactory. Then, moment capacity of beams and columns are evaluated and compared. EC8 stipulates that columns must have a moment capacity of 1.30 times the sum of the moment capacity of beams framing at that joint. This ensures beams are the initial failure mode.

**Note**: Deflection checks are performed for individual members only.

**D. Engineering Theory**

This section contains technical reference data on the methodology behind concrete design used in the Concrete Design workflow.
D. Design Messages

The design is performed on the selected members from the current Design Group and the parameters in the associated Design Brief. Each section is designed and a reinforcement cage is identified. The results of all the sections are then considered and a final rationalized cage is defined that requires the minimum area of reinforcement, but still matching all the design requirements including spacing and cracking checks.

If there are any issues arising form the design that results in either a partial or fully incomplete design for one or more of the design members, then these are reported in a Design Messages dialog at the end of the design of all of the members. Note that on models where a large number of members are being designed, with a large number of load cases, then the member that is currently being designed is displayed on the lower left side of the status bar.

On completion of the design, the members are color-coded to indicate their status. The colors can be set using the Colour Manager dialog (on page 1132).

D. Design Codes

The information that the design uses is determined by the design code associated with the design group.

D. Australian Concrete design per AS 3600:2001

Two design briefs for the Australian concrete design code AS 3600: 2001 have been included in the Concrete Design. The design principles utilized by these are defined in:

<table>
<thead>
<tr>
<th>Code Ref</th>
<th>Description</th>
</tr>
</thead>
</table>

D. AS 3600 Beam Design Principles

Design is performed per AS 3600-2001. Steel Strength reduction factors are taken from Table 2.3. Characteristic strength of materials are used based on section 6

Strength of Beams

Beams are designed for flexure, and shear. The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Lateral bending can be considered if user selects the option. Compression reinforcement is provided where required.

Flexure design is done based on the rectangular stress block defined in clause 8.1.2.2

\[ \gamma = [0.85 = 0.007(f_c - 28)] \]

Minimum Strength requirement as per 8.1.4

\[ \frac{A_{sd}}{b \cdot d} \geq 0.22 \left( \frac{D}{d} \right)^{2} \frac{f'c}{f_{sf}} \]

Requirements for shear reinforcement Clause 8.2.5

Where \( V^* \leq \phi V_{uc} \), no shear reinforcement is required, except that where the overall depth of the beam exceeds 750 mm, minimum shear reinforcement shall be provided in accordance with Clause 8.2.8

Where \( V^* > \phi V_{u,min} \). Shear reinforcement shall be provided in accordance with clause 8.2.10

Shear strength limited by web crushing: Maximum shear force resisted by element as per the clause 8.2.6
Design

D. Concrete Design

\[ V_{u,\text{max}} = 0.2 \, f'_c b_v d_0 \]

Shear Strength of a beam excluding shear reinforcement

\[ V_{uc} = b_1 b_2 b_3 d_0 (A_{st} f'_c / b_v d_0)^{1/3} \]

Strength of beams in shear 8.2 section

- **D. AS 3600 Beam Design Brief dialog** (on page 1241)
- **D. AS 3600 Column Design Brief dialog** (on page 1244)

D. AS 3600 Column Design Principles

Design has been carried out based on the code provisions in AS 3600-2001. Steel Strength reduction factors are taken from Table 2.3. Characteristic strength of materials are used based on section 6.

1. Design procedure carried out based on clause 10.2, 10.2.1 and 10.2.3.
2. Short column design based on 10.3
3. Design of slender columns based on 10.4
4. Minimum bending moment not less than \( N^* \) times 0.05\( D \), where \( D \) is the overall depth of the column in the plane of the bending moment.
5. Radius of gyration may be taken as 0.3\( D \), where \( D \) is the overall dimension in the direction in which stability is being considered and for circular cross-section, \( r \) may be taken as 0.25\( D \).
6. Biaxial bending and compression based on clause 10.6.5
7. Reinforcement requirements for columns: 10.7.1 Limitations on longitudinal steel:
   a. less than 0.01\( A_g \)
   b. Not exceed 0.04\( A_g \)

**D. Canadian Concrete Design per CAN/CSA-A23.3-04 (R2010)**

Two design briefs for CAN/CSA-A23.30-04 (R2010) (including updates 1, 2, and 3) are available in the Concrete Design. The design principles utilized by these are defined in:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Design of Concrete Structures</td>
</tr>
<tr>
<td>Revision</td>
<td>2010 (Reaffirmed year by CSA)</td>
</tr>
</tbody>
</table>

D. CAN/CSA-A23.3-10 Beam Design Principles

The CAN/CSA-A23.3-10 Beam Design Brief is for single or multi-span, prismatic, rectangular solid, or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to **D. Suitable Member Properties** (on page 1006) for more details.

Beams are designed for flexure, torsion, and shear only. Each member is divided into equally spaced sections along its length and the design is performed at each of these locations. You can specify the number of segments to be considered (between 4 and 25) for each span. Sections are also taken at the face of supports and at locations of the maximum positive and negative bending moments.

Design for Flexure
The main (longitudinal) reinforcement is calculated for both sagging and hogging moments (i.e., positive and negative moment, respectively) on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of the design forces, and thus, at each of the defined sections the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment values from the analysis.

The beam is then divided into sub-beams, those that can use the same reinforcement cage and having

- a. Same overall beam size
- b. Same cover requirements

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement pattern is calculated for the range of bars specified in the Design Brief. The program does not have a limit on the number of bars in any one layer as long as the spacing requirements specified in the code are satisfied. The program can handle a maximum of four layers of reinforcement, two each for the top and bottom layers.

The program then performs a check at each of the defined sections to determine the number of bars, if any, that can be cut off. The reinforcement bars will not be curtailed at these sections in the following cases:

- a. If the bars are required for compression, or
- b. If curtailing these bars would result in a failure of crack-width checks, or
- c. If curtailing these bars would result in a failure of the minimum reinforcement checks.

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, $F_{z}$, acting on the beam. The minor axis shear forces are not considered in the design.

The bar size for the shear links and the minimum number of shear legs to be provided are specified in the Design Brief. Therefore, the required spacing for minimum links can be defined. The program then checks each section to determine the shear force $V_{Ed}$ and concrete shear capacity $V_{Rd,c}$. From this, the section is classified as either a minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, $\nu$, and concrete shear capacity, $\nu_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.
If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

![Diagram](image)

- D. CSA-A23.3-10 Beam Design Brief dialog (on page 1262)

D. CAN/CSA-A23.3-10 Column Design Principles

The CAN/CSA-A23.3-10 Column Design Brief is for prismatic, solid rectangular, or circular shaped members. Members may be built up from multiple elements, but only the member end moments are considered. Therefore, only single height columns are recommended.

Design Principles

Columns are designed for axial force and biaxial end moments, as well as biaxial shear. Provided reinforcement is calculated by the program based on the forces generated from the analysis model and the code clauses outlined below.

The main reinforcing bars may be modified to allow for other bars passing through the section and then rechecked to ensure that the design requirements are satisfied.

All selected load combinations are used to calculate the required reinforcement. The combination which produces the maximum required reinforcement area is called the “Guiding Load Case”, and the bar arrangement is chosen based on that combination. The detailed printout of the design calculations is for that combination.

Code Clauses Implemented

The requirements of CAN/CSA-A23.3-10 utilized in the design module are as follows:

Materials

8.4.2-3
8.5.1 – Design calculations are based on the specified yield strength of reinforcement. A warning is reported if the specified yield strength is greater than 500 MPa.
8.6.1.1
8.6.2.2 – The modulus of elasticity of concrete is calculated using equation 8-1 in the code. The specified density, $\gamma_c$, is used in the equation but if it is outside of the range 1,500 to 2,500 kg/m$^3$, a warning is reported. Altern
8.6.4-5 – The modulus of rupture, $f_r$, is calculated use equation 8-3.
10.1.3
10.1.5-6

Minimum Reinforcement
7.4.1.1
7.4.1.3
7.6.5.1-2 – Bundled bars are not considered.
10.9.1-4 – The minimum reinforcement for columns is 0.01×A_g. If reinforcement exceeds 0.04×A_g, a warning is reported. If reinforcement exceeds 0.08×A_g, a failure is reported. A_g is the gross cross sectional area of the column. A minimum of 4 or 6 bars is required for rectangular or round columns, respectively (for irregularly shaped columns, no design check is performed).
10.10.5

Ultimate Limit State

10.1.2 - The strain in the reinforcement and concrete are assumed to be directly proportional to the distance from the neutral axis. For deep flexural members, the design is performed using the plane sections remain plane assumption, but a warning is reported.
10.1.5 – The tensile strength of concrete is neglected.
10.9.4
10.10.4-5
11.2.8.1-2
11.2.9.1
11.2.10
11.3.1
11.3.3-4
11.3.5.1
11.3.6.4
11.3.8.1
11.3.8.3
11.3.9.2-3
11.3.10.1-6

Development Length

12.1.2
12.2.1-2
12.2.4-5
12.3.1-3
12.5.1-3

D. Chinese Concrete design per GB50010

Code Ref GB50010-2002
Description Chinese Standard, Concrete Structures, GB50010
Revision 2002

Release 2007
D. Selected Specifications
Chinese concrete design specifications to achieve the following specifications:

- *Concrete Structure Design Code* (GB 50010-2002)
- *Technical specification for concrete high-rise building* (JGJ 3-2002)
- *Structural Load code for the design of building structures* (GB 50009--2001 (2006))
- *Seismic Design Code of Buildings* (GB 50011-2001)

Unless specifically stated in this document, its provisions are derived from standard reference design of concrete structures (GB 50010-2002).

## Nomenclature

### Material Properties

- $E_c$: elastic modulus of concrete;
- $E_{fc}$: Concrete Fatigue Deformation modulus;
- $E_s$: modulus of elasticity of reinforced;
- $C_{20}$: that the standard cube strength of concrete strength value 20N/mm$^2$;
- $f'cu$: a side length of 150mm concrete cube compressive strength of the construction phase;
- $f_{cu, k}$: a side length of 150mm cube of concrete compressive strength of standard value;
- $f_{ck}$, $f_c$: standard value of concrete compressive strength, design values;
- $f_{tk}$, $f_t$: the standard value of axial tensile strength of concrete, the design value;
- $f'_{ck}$, $f'tk$: Construction of the concrete axial compression, axial tensile strength of standard value;
- $f_{yk}$, $f_{ytk}$: in reinforced, prestressed reinforced strength standard value;
- $f_y$, $f'_{y}$: ordinary steel tensile and compressive strength of the design value;
- $f_{py}$, $f'_{py}$: prestressed reinforcement tensile, compressive strength design value.

### Capacity and Resistance

- $N$: design value of axial force;
- $N_k$, $N_q$: according to the standard combination of load effects, quasi-permanent combination of computing the value of the axial force;
- $N_{ux}$, $N_{uy}$: axial force on the X axis, Y axis of the eccentric or eccentric compression tension design value of bearing capacity;
- $M$: bending moment design value;
- $M_k$, $M_q$: according to the standard combination of load effects, quasi-permanent combination of calculated bending moment;
- $M_u$: Component design flexural capacity value;
- $M_{cr}$: Bending cross section of the cracking moment value;
- $T$: torque design value;
- $V$: shear design values;
- $V_{cs}$: oblique section of concrete and stirrups on shear strength design values;
- $F_l$: local load design value or the concentration of counter-force design value.
σck, σcq the standard combination of load effects, quasi-permanent combination of checking the
dge of the concrete crack under normal stress;
σpc generated by the pre-tension concrete normal stress;
σtp, σcp concrete principal tensile stress, principal stress;
σfc, max, σfc, min fatigue tension zone when Checking the edge of fiber reinforced concrete compression
zone or the maximum stress, minimum stress;
σs, σp is set in the vertical plane bearing capacity of ordinary steel, prestressing stress;
σsk according to the standard combination of load effects calculated longitudinal tensile steel
stress or equivalent stress;
σcon tensioning control stress;
σp0 prestressed concrete method to force the point of zero stress when the stress of
prestressed reinforcement;
σpe effective prestress prestressed reinforcement;
σl, σ'l tension zone, compression zone in the corresponding stage of prestressed reinforced the
value of prestress loss;
τ shear stress of concrete;
ωmax according to the standard combination of load effects and to consider the impact of long-
term effect of the maximum crack width calculation.

Geometric Parameters

a, a' longitudinal tensile reinforcement force point, longitudinal compressive force point to sections of
reinforced near-edge distance;
as, a's longitudinal non-prestressed tensile reinforcement force point, the longitudinal non-prestressed
compression steel sections together to point to the near edge of the distance;
ap, a'p area of longitudinal prestressing tension force point, the compression zone of longitudinal
prestressing force points to the section near the edge distance;
b width of rectangular section, T-shaped, I-shaped cross-section of the web width;
bf, b'f T-shaped or I-shaped cross section in tension zone, compression zone of the flange width;
d the diameter of the bar diameter or cross section;
c the thickness of concrete;
e, e' axial force point to point longitudinal tensile reinforcement force, vertical compression
reinforcement force point distance;
e0 axial force on the section center of gravity of eccentricity;
ea Add eccentricity;ei initial eccentricity;
h Height of the Cross;
h0 effective height of cross section;
hf, h'f T-shaped or I-shaped cross section in tension zone, compression zone of the flange height;
Design

D. Concrete Design

i section radius of gyration;
rc radius of curvature;
la longitudinal tensile reinforcement of the anchorage length;
l0 Beam Calculation of span or length of columns;
s component axis along the direction of the spacing of transverse reinforcement, the spacing of spiral reinforcement or stirrups spacing;
x concrete compression zone;
y0, yn conversion section focus, focus to the calculation of the net section of the fiber distance;
z longitudinal tensile reinforcement force to the concrete compression zone the distance between the points together;
A component-sectional area;
A0 component conversion section area;
An member net section area;
As, A's tension zone, compression zone of non-prestressed longitudinal cross-sectional area;
Ap, A'p tension zone, compression zone cross-sectional area of longitudinal prestressing;
Asv1, Ast1 in shear, by the calculation of single-leg stirrups twisted cross-section area;
Astl Torsion calculation of longitudinal torsion access to all the cross-sectional area of non-prestressed reinforcement;
Asv, Ash limb within the same section of vertical, horizontal steel hoop or distribution of all cross-sectional area;
Asb, Apb the same plane bent non-tensioned, prestressed bent steel bar cross-sectional area;
Al Concrete local compression area;
Acor steel mesh, spiral reinforcement or stirrups within the inner surface of the concrete core area;
B Bending stiffness of the section;
W cross section by pulling the edge of the elastic resistance moment;
W0 transformed section by pulling the edge of the elastic resistance moment;
Wn net section tensile edge of the elastic resistance moment;
Wt section by twisting the plastic resistance moment;
I moment of inertia;
I0 transformed section moment of inertia;
In net section moment of inertia.

Calculation Coefficient and Other

α1 compression zone of concrete rectangular stress diagram of the stress value and design value of concrete compressive strength ratio;
αE reinforced concrete elastic modulus and elastic modulus ratio;
Concrete strength coefficient;  
$\beta_1$ rectangular stress block compression zone and the neutral axis height (axis in the compression zone to the edge of the distance) ratio;  
$\beta_l$ Local Compressive concrete strength coefficient;  
$\gamma$ the section of concrete to resist the plastic moment of impact factor;  
$\eta$ eccentric compression effects of the second order moment of the axial force eccentricity magnification factor;  
$\lambda$ Calculation of cross sections of shear span ratio;  
$\mu$ friction coefficient;  
$\rho$ the reinforced longitudinal reinforcement ratio;  
$\rho_{sv}, \rho_{sh}$ vertical stirrups, stirrups, or the vertical distribution of horizontal bar, horizontal distribution of steel reinforcement ratio;  
$\rho_v$ indirectly, the volume of steel reinforcement ratio or the hoop;  
$\varphi$ stability factor of axial compression members;  
$\theta$ consider the long-term effect on the deflection load increases the impact factor;  
$\psi$ crack between the longitudinal bar strain coefficient of uniformity.

Concrete Materials

1. Elastic modulus of concrete calculated as follows (note the provisions of 4.1.5):  
$$E_c = \frac{10 \times 10^5}{2.2 + \frac{24.7}{f_{cu,k}}}$$

2. Standard values of concrete compressive strength and design values were calculated the following formula (note the provisions of 4.1.3):  
$$f_{ck} = 0.88\alpha_c f_{cu,k}$$  
$$f_c = f_{ck}/Y_c = f_{ck}/1.4$$  
C50 and the following take $\alpha_c1 = 0.76$, on the C80 take $\alpha_c1 = 0.82$, according to the linear law of change in the middle.  
Of the C40 take $\alpha_c2 = 1.0$, on the C80 take $\alpha_c1 = 0.87$, change in the middle by a linear law.  

3. The standard value and design of axial tensile strength values were calculated as follows (note the provisions of 4.1.4):  
$$f_{tk} = 0.88\left(0.395\right)f_{cu,k}^{0.55}\left(1 - 1.645\delta\right)^{0.45}\alpha_c2$$  
$$f_c = f_{tk}/Y_c = f_{tk}/1.4$$

Limit State Design

For the ultimate limit state, structural members shall be the basic combination of load effects or accidental combination of the following limit state design equation:

\[ \gamma 0 S \leq R (3.2.3-1) \]

where

- \(\gamma 0\) = importance factor, input by the user in the program, on the security level for the one or the design life of more than 100 years and structural components, should not be less than 1.1; on the security level for the design life span of two or 50 years of structural members, not less than 1.0; on the security level is 3 or the design life of 5 years and below the structural members, not less than 0.9; in seismic design, structural elements do not take into account the importance of factors;

- \(S\) = the ultimate state of the load effect combination of the design value.

- \(R\) = design value of bearing capacity of structural members; in seismic design, seismic bearing capacity divided by the adjustment factor \(\gamma RE\);

For the limit state, structural components should be separately according to the standard combination of load effects, quasi-permanent combination or standard combination, and to consider long-term effects of limit state design with the following expression:
Design

D. Concrete Design

\[ S \leq C \ (3.3.1) \]

where

\[
S = \text{limit state of load effect combination of value;}
\]

\[
C = \text{structural members meet requirements under normal use of the deformation, crack width and stress limits.}
\]

D. Design Capacity of Beams

Beams along the bearing capacity of beams through a long span of each cross section, beam cross section of the design include a component of the capacity of checking and regulating the provision of construction or other design requirements such as thickness reinforcement, reinforcement ratio, bar diameter.

General Provisions

1. Flexural capacity is calculated according to the following fundamental assumptions:
   a. section to maintain plane strain;
   b. does not take into account the tensile strength of concrete;

2. Compressive stress-strain relationship of concrete in accordance with the provisions of Article 7.1.2-3 standard values.
   a. Ultimate compressive strain of concrete is in accordance with section following formula:

   \[
   \varepsilon_{cu} = 0.0033 - (f_{cu,k} - 50) \times 10^{-5}
   \]  
   (7.1.2-5)

   where

   \[
   \varepsilon_{cu} = \text{cross section of the concrete ultimate compressive strain, while in the non-uniform compression, press formula (7.1.2-5) calculations, such as the calculation of } \varepsilon_{cu} \text{ is greater than 0.0033, is taken as 0.0033; when in axial When pressure is taken as } \varepsilon_0; \]

   \[
   f_{cu,k} = \text{concrete cube compressive strength of standard value}
   \]

   \[
   \beta_1 = \text{coefficient, when the concrete strength when no more than C50, } \beta_1 \text{ taken as 0.8, when the concrete strength grade of C80 time, } \beta_1 \text{ taken as 0.74, during determined by linear interpolation.}
   \]

   \[
   \alpha_1 = \text{rectangular stress diagram of the stress is taken as design value of concrete compressive strength } f_c \text{ multiplied by the coefficient } \alpha_1. \text{ When the concrete strength when no more than C50, } \alpha_1 \text{ taken as 1.0, when the concrete strength grade of C80 time, } \alpha_1 \text{ taken as 0.94, during determined by linear interpolation.}
   \]

3. Longitudinal tension and compression zone of reinforced concrete damage yield simultaneously, the relative height of compression zone limits \( \xi_b \) By the following formula:

   \[
   \xi_b = \frac{\beta_1}{1 + \frac{f_y}{E_s f_{cu}}}
   \]  
   (7.1.4-1)

Net Concrete Cover Thickness

Input by the user of longitudinal force ordinary reinforced and prestressed steel, the concrete cover thickness (reinforced concrete surface to the outer edge of the distance) should not be less than the nominal diameter of steel, and shall comply with Table 9.2.1 of GB50010-2002 requirements.

General Provisions on Seismic Design
Seismic fortification intensity level and
Provide beam seismic rating, fortification intensity, structure type and component type of input. Program based on user input seismic fortification intensity levels and components of the beam design and construction inspection.

Seismic bearing capacity adjustment factor
Consider the combination of earthquake concrete structure, its cross-section bearing capacity of the internal forces generated by seismic load bearing capacity divided by the seismic design value adjustment factor $\gamma_{RE}$. Seismic bearing capacity adjustment factor $\gamma_{RE}$ 11.1.6 in accordance with GB50010-2002 form used. For the beam component, $\gamma_{RE}$ value is 0.75.

Calculation of Concrete Beams
Bearing Capacity
1. Rectangular Bending Capacity: rectangular cross section or flange in the tension side of the inverted T-shaped cross-section flexural members, the flexural capacity should meet the following requirements:

   \[ M \leq \alpha_1 f_c b x (h_0 - x/2) + f_y A'_s (h_0 - \alpha'_s) \]  

   Concrete Compression Zone according to the following formula:

   \[ \alpha_1 f_c b x = f_y A'_s + f_{py} A_p \]  

   Concrete Compression Zone still should meet the following conditions:

   \[ x \leq \xi_b h_0 \]  

   \[ x \geq 2\alpha'_s \]  

2. When included in the calculation of longitudinal compression reinforcement general, should meet the GB50010-2002 formula (7.2.1-4) conditions; if not satisfied this condition, the flexural capacity should meet the following requirements:

   \[ M \leq f_{py} A_p (h - a_p - a'_s) + f_y A_s (h - a_s - a'_s) + (\sigma'_p - f_{py}) A'_p (a'_p - a'_s) \]  

3. Bending Flexural bearing capacity calculations, as required by the structure or by checking Limit State requirements configured sectional area of longitudinal tensile steel bending capacity requirements greater than the area of reinforcement, the calculation of concrete compression Height $x$, only the conditions included in the required bending capacity vertical cross-section area of tensile steel.

4. T-Section Bending Capacity: flange in the compression zone of the T shape, I shaped cross-section flexural members (Figure 7.2.2), its flexural capacity should meet the following requirements:

   a. When the following conditions are met

      \[ f_y A_s + f_{py} A_p \leq \alpha_1 f_c b' (h_0 - h' f/2) + f_y A'_s (h_0 - \alpha'_s) + (\sigma'_p - f_{py}) A'_p \]  

      Should be a width $b'$ rectangular cross section;

   b. When satisfied equation (7.2.2-1) the conditions

      \[ M \leq \alpha_1 f_c b x (h_0 - x/2) + \alpha_1 f_c (b' f - b) h' f (h_0 - h' f/2) + f_y A'_s (h_0 - \alpha'_s) + (\sigma'_p - f_{py}) A'_p (h_0 - \alpha'_p) \]  

   Concrete Compression Zone according to the following formula:

   \[ \alpha_1 f_c b x + (b' f - b) h' f = f_y A_s + f_y A'_s + f_{py} A_p + (\sigma'_p - f_{py}) A'_p \]  

Concrete compression zone height limit of seismic
For the seismic component: in the calculation, included in the longitudinal compression reinforcement in concrete compression zone of beam end shall meet the following requirements:

A seismic level
ξb ≤ 0.25 \quad \text{(11.3.1-1)}

Second, three seismic rating
ξb ≤ 0.35 \quad \text{(11.3.1-2)}

Reinforcement ratio test

1. Configuration bar when the protective layer thickness in accordance with user input calculated as; to complete the inspection section bearing capacity of reinforced configuration, when the actual use of force reinforced the role of location as a point of steel.

2. Flexural members, offset tension, axial tension component side of the minimum tensile steel reinforcement ratio of 0.2 and $45f_t/f_y$ the larger value;

3. The seismic structure:

<table>
<thead>
<tr>
<th>Seismic Level</th>

</tr>
</tbody>
</table>

Beam, the lower the minimum longitudinal steel reinforcement ratio, non-seismic design should not be less than 0.30%, respectively; seismic design, special one, one and two respectively, not less than 0.60%, 0.50% and 0.40%; (JGJ 10.2.8-1)

4. The largest component seismic reinforcement rate: end of the beam longitudinal reinforcement ratio of tension reinforcement should not exceed 2.5%.

Reinforcing the principles and methods of allocation

1. As selected through a long beam under the critical section, thus setting the upper and lower steel reinforcement combinations.

A. Through long tendons meet the upper

i. At least two, the corner bar.

ii. Of the secondary seismic level, the bar diameter of not less than 14mm, and should not be less than the beam, respectively top and bottom ends of the longitudinal section of the reinforced area of the larger 1 / 4; on 3, 4 seismic rating, bar diameter not less than 12mm.

iii. The first row of steel from the non-pass a long column (beam) side has been extended to ln / 3 position; second row extend ln / 4 position; ln value is defined as: for end bearing, net-based cross-span; For the intermediate bearing, ln on both sides for the bearing of a large net across the span.

iv. Reinforced concrete longitudinal beam support section of negative moment reinforcement in tension should not be cut off in the tension zone. When to cut, in accordance with the provisions of reinforcement anchorage length (GB50010-2002 9.3.1), retained after anchoring length cut off under stress conditions.

2. Through the lower part of a long bar to meet:

i. At least two, the corner bar.
ii. When the earthquake, the full reach into bearing.

iii. Non-seismic, do not reach into the lower bearing of the beam longitudinal reinforcement cut off dot pitch bearing edge distance 0.1ln.

Test Oblique Section

Program based on user input information to carry out shear reinforcement component of shear resistance test, specified as follows:

Non-Seismic Shear Resistance Test

1. Rectangular, T-shaped and I-shaped cross-section flexural members, the shear section shall meet the following conditions:

   When the $h_w / b ≤ 4$:
   \[ V ≤ 0.25β_c f_c bh_0 \]

   When the $h_w / b ≥ 6$:
   \[ V ≤ 0.2β_c f_c bh_0 \]

   Combination of box beam cross section the maximum shear design values shall meet the following requirements:
   \[ V ≤ 0.2β_c f_c bh_0 \]

2. Not configured stirrups and bent sheet metal reinforcement general bending members, the diagonal section of the shear capacity shall meet the following requirements:

   \[ V ≤ 0.7β_h f_t bh_0 \]

   \[ β_h = (800 / h_0) ^ {1 / 4} \]

3. Rectangular, T-shaped and I-shaped cross-section flexural members in general, when the only configuration stirrups, its diagonal section of the shear capacity shall meet the following requirements:

   \[ V ≤ 0.7f_t bh_0 + 1.25 f_{yy} (A_{sv} / s) h_0 \]

Seismic shear resistance test

1. Consider the combination of the framework of the seismic design of beam end shear value $V_b$ according to the actual value;

2. Consider the combination of the frame beam earthquake, when the inter-high ratio of $l0 / h > 2.5$, its shear cross-section should conform to the following conditions:

   \[ V_b ≤ 1 (0.20β_c f_c bh_0) / γRE \]  \hspace{1cm} \text{(11.3.3)}

   where

   \( β_c = \) concrete strength factor: When the concrete strength less than C50, the take $β_c = 1.0$; when the concrete strength grade of C80, the take $β_c = 0.8$; during determined by linear interpolation.

3. Consider the combination of earthquake rectangular, T-shaped and I-shaped cross-section of the frame beam, the Shear capacity should meet the following requirements:

   \[ V_b ≤ 1 [0.42f_t bh_0 + 1.25 f_{yy} A_{sv} h_0 / s] / γRE \]

Tie Ratio Test

1. Confining rate: When $V > 0.7f_t bh_0$, the hoop reinforcement ratio $\rho_{sv} [\rho_{sv} = A_{sv} / (b_s) (b_s)]$ not be less than $0.24f_t / f_{yy}$;

2. Seismic conditions:
Along the beam length of stirrup reinforcement ratio $\rho_{sv}$ should meet the following requirements:

**Seismic level 1:**

$$\rho_{sv} \geq 0.30 \frac{f_t}{f_{yv}}$$

**Seismic level 2:**

$$\rho_{sv} \geq 0.28 \frac{f_t}{f_{yv}}$$

**Seismic level 3,4:**

$$\rho_{sv} \geq 0.26 \frac{f_t}{f_{yv}}$$

3. High-rise building structures, seismic rating for the particular level of reinforced concrete structures shall meet the basic requirements of a seismic level, the beam end encryption District hoop structure confining rate increases of 10%.

4. Box beam supports of encrypted area with hoop hoop smallest, non-seismic design should not be less than 0.9$f_t/f_{yv}$; seismic design, the special one and one and two respectively, not less than 1.3$f_t/f_{yv}$, 1.2$f_t/f_{yv}$ and 1.1$f_t/f_{yv}$. ([JGJ 10.2.8 - 2])

**Spacing**

1. The maximum stirrup spacing:

   a. Non-seismic:

   **Table 75: The maximum beam stirrup spacing (mm), Table 10.2.10**

<table>
<thead>

3. Box beam supports of (left side column height within the beam section 1.5) stirrups should be encrypted, encrypted area stirrup diameter of not less than 10mm, spacing should not exceed 100mm. *(JGJ-10.2.8-3)*

Minimum diameter stirrups:

1. # Non-seismic design: A cross-section height h > 800mm of the beam, the stirrup diameter not less than 8mm; on the beam height h ≤ 800mm beam, the stirrup diameter not less than 6mm. Beam with vertical
D. Concrete Design

compression reinforcement computing needs, the stirrup diameter of not less than the vertical compression reinforcement should be 0.25 times the diameter.

2. Seismic design: minimum diameter shall meet the requirements of Table 6.3.2-2, when the end of the beam longitudinal reinforcement ratio greater than 2%, the minimum diameter of the table in the stirrups should be increased 2mm.

Side bar (waist bars) layout

When the beam web height \( h_w \geq 450\text{mm} \), the two sides of the beam height profile along the vertical structure should be reinforced, each side of the vertical structural steel (not including the beam, the lower part of the reinforced and erect steel) cross-section area of not web-sectional area should be less than \( 0.1\% bh_w \), and the pitch should be less than 200mm. Here, the web height \( h_w \) according to GB50010-2002 7.5.1 Article access.

D. Design Capacity of Columns

Concrete column design through the user-specified component type, seismic parameters such as standardized test grades, the program selected by the user load combinations and design parameters for the design and reinforcement, testing results and design process will be output to the report.

General Provisions

See “General Provisions” (on page 1031) for Beam Design.

Column Capacity Under Axial Load

Axial compression component capacity

Axially loaded reinforced concrete structures, when the configuration of the stirrup meet GB50010-2002 the provisions of section 10.3, which is cross-section compression capacity should meet the following requirements:

\[
N \leq 0.9\phi(f_cA + f_yA_{s'})
\]  
(7.2.15)

When the vertical steel reinforcement ratio greater than 3%, the formula (7.2.15) in \( A \) Should use \( (A-A') \) in its place.

Axially loaded reinforced concrete structures, when the configuration of the screw or welded steel ring indirectly found GB50010-2002 the provisions of section 10.3, which is cross-section compression capacity should meet the following requirements:

\[
N \leq 0.9(f_cA_{cor} + f_yA_{s'} + 2\alpha f_yA_{sat})
\]  
(7.3.2-1)

Eccentric compression component capacity

Eccentric rectangular cross section compression member compression capacity should meet the following requirements:

\[
N \leq \alpha_1 f_c bx + f_y A_{s'} - \sigma_y A_s
\]  
(7.3.4-1)

\[
N e \leq \alpha_1 f_c bx(h_0 - x/2) + f_y A_{s'}(h_0 - a_s)
\]  
(7.3.4-2)

Uniform configuration along the peripheral ring of longitudinal reinforcement section eccentric compression, which is cross-section compression capacity should meet the following requirements:

\[
N \leq a_1 f_c A(1 - \frac{\sin 2n\alpha}{2n\alpha}) + (a - a_1)f_yA_s
\]  
(7.3.7 - 1)

\[
N\eta e_i \leq a_1 f_c A \frac{\sin 3\alpha}{n} + f_y A_{s'} \frac{\sin 3\alpha + \sin n\alpha_1}{n}
\]  
(7.3.7 - 2)
Axial tension component capacity

Axial tension member tensile capacity of normal section shall meet the following requirements:

\[
N \leq f_y A_s
\]  \hspace{1cm} (7.4.1)

Eccentric tension component capacity

Eccentric rectangular symmetric reinforcement for tension members, both large and small offset tension of the situation, may according to formula (7.4.2-2) calculated:

\[
N_{e'} \leq f_y A_s (h'0 - a_s) + f_{py} A_p (h'0 - ap)
\]  \hspace{1cm} (7.4.2-2)

Calculation of Oblique Section

Eccentric compression

Rectangular reinforced concrete eccentric compression, the Shear Capacity meet the following requirements:

\[
V \leq \frac{1.75}{\lambda + 1} f_y b h_o + f_{yu} \frac{A_{sv}}{s} h_o + 0.07N
\]  \hspace{1cm} (7.5.12)

Shear span ratio calculation section the following provisions shall be drawn:

1. Columns on the kinds of structures, should take \(\lambda = M / (V h_o)\); on the frame structure of the frame column, when the inflection point in the story context, the desirability of \(\lambda = H_n / (2 h_o)\); when \(\lambda < 1\), take \(\lambda = 1\); when \(\lambda > 3\), the take \(\lambda = 3\); here, \(M\) for the calculation of the cross section and the shear design value \(V\) corresponding moment design value, \(H_n\) dear height for the column.

2. On the other eccentric compression, when the bear uniformly distributed load, take \(\lambda = 1.5\); when the bear meet GB50010-2002 section 7.3.4 provides a concentrated loads, taking \(\lambda = a / h_0\), when \(\lambda < 1.5\), the taking \(\lambda = 1.5\); when \(\lambda > 3\), the take \(\lambda = 3\); here, \(a\) for the concentrated load to the bearing or distance from the edge node.

Eccentric Tension Member

Eccentric rectangular cross-section of reinforced concrete tension members, the Shear Capacity meet the following requirements:

\[
V \leq \frac{1.75}{\lambda + 1} f_y b h_o + f_{yu} \frac{A_{sv}}{s} h_o + 0.07N
\]  \hspace{1cm} (7.5.14)

Seismic design of concrete columns

Longitudinal reinforcement force

Columns and pillars of steel frame configuration, should meet the following requirements

Box columns and pillars all vertical steel reinforcement percentage of the force should not be less than the values specified table 11.4.12-1 the same time, each side of the reinforcement ratio of not less than 0.2;

Box columns and pillars of strength in all the longitudinal reinforcement ratio should not exceed 5%. Column longitudinal steel should symmetric configuration. Column section size greater than 400mm, vertical spacing of reinforcement should not be greater than 200mm. When the level of design by an earthquake, and the column shear span ratio \(\lambda \leq 2\), the columns on each side of longitudinal steel reinforcement ratio should be less than 1.2%.

#### Notes:

a. A general refers to a single rectangular hoop or single circular hoop; spiral hoop that a single spiral reinforcement; composite hoop means rectangular, polygonal, circular or reinforcement consisting of stirrups stirrup; compound spiral hoop means spiral hoop and rectangular, polygonal, circular or reinforcement consisting of stirrups stirrup; continuous composite rectangular spiral refers to all the spiral hoop to hoop with a steel processed into the stirrups;

b. In the calculation of the volume of composite spiral hoop reinforcement ratio, one of the spiral reinforcement of the volume of non-conversion factor should be multiplied by 0.8;

c. On 1, 2, 3, 4 seismic rating column, the encrypted area of stirrups stirrup reinforcement ratio of the volume should not be less than 0.8%, respectively, 0.6%, 0.4% and 0.4%;

d. Concrete strength higher than C60, the stirrup should the composite hoop, composite or continuous composite rectangular spiral hoop; when the axial compression ratio is not greater than 0.6, the encryption region the value of the minimum stirrup according to values in the table should increase 0.02; when the axial compression ratio greater than 0.6, the appropriate values in the table increased by 0.03.

2. Box pillar should adopt the compound spiral hoop or crosswise composite hoop, the minimum transverse reinforcement characteristic values should be the value in Table 11.4.17 0.02 increase access to, and the volume reinforcement ratio of not less than 1.5%;

3. When the shear span ratio λ ≤ 2, the one, two, three seismic level of composite column should spiral hoop or crosswise composite hoop, the hoop reinforcement ratio of volume of not less than 1.2%; 9, when the degree of fortification should not be less than 1.5%.

---

**D. Egypt Concrete design per ECCS 203**

Concrete Design has two ECCS 203 design briefs, the design principles utilized by these are defined in:
D. ECCS 203 Beam Design Principles

The ECCS 203 Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to D. Suitable Member Properties (on page 1006) for more details.

Beams are designed for flexure, shear and torsion. For all these forces, all active beam loadings are pre scanned to identify the critical load cases at different sections of the beams. The total number of sections considered is defined in the General sheet of the parameters dialog box. It can be set to between 4 and 25 segments (per span), thus will be checked at the ends of these segments, plus the locations of the maximum forces.

Slenderness Effects and Analysis Considerations

STAAD provides the user with two methods of accounting for the slenderness effects in the analysis and design of concrete members. The first method is equivalent to the procedure presented in ECCS203-2004 equation 4-11. In this section, the code recognizes that additional moments induced by deflection are present and states that these 'secondary' moments are accounted for by the design formula in equation 6-38,6-37 etc. This is the method used in the design for concrete in STAAD.

Alternatively STAAD contains a PDELTA ANALYSIS facility, which allows the effects of these second order moments to be considered in the analysis rather than the design. In a PDELTA analysis, after solving the joint displacements of the structure, the additional moments induced in the structure are calculated. These can be compared to those calculated using the formulation of ECCS203-2004.

Design for Flexure

Maximum sagging (creating tensile stress at the bottom face of the beam) and hogging (creating tensile stress at the top face) moments are calculated for all active load cases at each of the above mentioned sections. Each of these sections are designed to resist both of these critical sagging and hogging moments. Currently, design of singly reinforced sections only is permitted. If the section dimensions are inadequate as a singly reinforced section, such a message will be permitted in the output. Flexural design of beams is performed in two passes. In the first pass, effective depths of the sections are determined with the assumption of single layer of assumed reinforcement and reinforcement requirements are calculated. After the preliminary design, reinforcing bars are chosen from the internal database in single or multiple layers. The entire flexure design is performed again in a second pass taking into account the changed effective depths of sections calculated on the basis of reinforcement provided after the preliminary design. Final provision of flexural reinforcements are made then. Efforts have been made to meet the guideline for the curtailment of reinforcements as per ECCS203-2004. Although exact curtailment lengths are not mentioned explicitly in the design output (finally which will be more or less guided by the detailer taking into account of other practical consideration), user has the choice of printing reinforcements provided by STAAD at 13 equally spaced sections from which the final detailed drawing can be prepared.

Design for Shear

Shear reinforcement is calculated to resist both shear forces and torsional moments. The shear checks are performed at the same locations along each span as for the bending check including the additional locations for the maximum shear forces amongst the active load cases and the associated torsional moments. Shear capacity calculation at different sections without the shear reinforcement is based on the actual tensile reinforcement provided by STAAD. Two-legged stirrups are provided to take care of the balance shear forces acting on these sections.

Related Links
D. ECCS 203 Column Design Principles

The ECCS 203 Column Design Brief is for prismatic, rectangular solid or circular shaped members. Members may be built up from multiple elements, but only the member end moments are considered, so only single height columns are recommended.

Design Principles

Columns are designed for axial force and biaxial bending at the ends. All active loadings are tested to calculate reinforcement. The loading which produces maximum reinforcement is called the critical load and is displayed. The requirements of ECCS203-2004 equation 6-37,6-38,6-41 etc are followed, with the user having control on the effective length parameters. Bracing conditions are controlled by using the BRACE parameter. The program will then decide whether or not the column is short or slender and whether it requires additional moment calculations.

D. European Concrete Design per Eurocode EC2: 2004

Two additional design briefs for Eurocode 2: 2004 have been included in the Concrete Design. The design principles utilized by these are defined in:

<table>
<thead>
<tr>
<th>Code Ref</th>
<th>Description</th>
<th>Revision</th>
</tr>
</thead>
</table>

D. Eurocode 2:2004 Beam Design Principles

The Eurocode 2:2004 Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to D. Suitable Member Properties (on page 1006) for more details.

Beams are designed for flexure and shear only. Each member is divided into equally spaced sections along its length and the design is performed at each of these locations. The user can specify the number of segments to be considered (between 4 and 25) for each span. Sections are also taken at face of supports and at locations of the maximum positive and negative bending moments.

Design for Flexure

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of the design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment values from the analysis.

The beam is then divided into sub-beams, those that can use the same reinforcement cage and having

- Same overall beam size
- Same covers requirements
For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement pattern is calculated for the range of bars specified in the Design Brief. The program does not have a limit on the number of bars in any one layer as long as the spacing requirements specified in the code are satisfied. The program can handle a maximum of 4 layers of reinforcement, two each for the top and bottom layers.

The program then performs a check at each of the defined sections to determine the number of bars, if any, that can be curtailed. The reinforcement bars will not be curtailed at these sections in the following cases:

a. If the bars are required for compression or
b. If curtailing these bars would result in a failure of crack-width checks or
c. If curtailing these bars would result in a failure of the minimum reinforcement checks.

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, $F_z$ acting on the beam. The minor axis shear forces are not considered in the design.

The bar size for the shear links and the minimum number of shear legs to be provided are specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear force $V_{Ed}$ and concrete shear capacity $V_{Rd,c}$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, $\sigma$, and concrete shear capacity, $\sigma_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.
Anchorage and Bond Lengths

Anchorage and bond lengths are calculated in accordance with the requirements of Eurocode 2. They can be displayed graphically on the main reinforcement diagram and are used for the schedule table and export to rebar detailing programs.

Code Clauses Implemented

D. Eurocode 2:2004 Column Design Principles

The Eurocode 2:2004 Column Design Brief is for prismatic, solid rectangular or circular shaped members. Members may be built up from multiple elements, but only the member end moments are considered. Hence only single height columns are recommended.

Design Principles

Columns are designed for axial force and biaxial end moments, as well as biaxial shear. Reinforcement is provided by the program based on the forces generated from the analysis model and the code clauses outlined below.
The main reinforcing bars may be modified to allow for other bars passing through the section and then re-
checked to ensure that the design requirements are satisfied.

All selected load combinations are used to calculate the required reinforcement. The combination which
produces the maximum required reinforcement area is called the Guiding Load Case, and the bar arrangement is
chosen based on that combination. Detailed printout of the design calculations provided is for that combination.

• D. National Annex Values dialog (on page 1297)

D. Eurocode 2:2004 Slab Design Principles

The Eurocode 2: 2004 Slab Design Brief is for any slab modeled with finite elements, regardless of boundary restraint conditions.

Slabs are designed for bending in two orthogonal directions for both hogging and sagging moments. Designs for shear or punching shear checks are not included.

Analysis results for plate elements that form a 'Slab' are used to generate design moments with respect to the axes of the slab. These moments are then used to generate required reinforcement contours. Note that no account is taken of the requirements for embedment or development of reinforcement.

**Tip:** The level of accuracy of results depends on the meshing density used to model the slabs. It is recommended that users examine the accuracy of the model at the analysis stage and ensure satisfactory results are obtained prior to the design stage.

Code clauses implemented are 9.3.1.1 (1) and (3) (excluding rules for concentrated loads).

Only reinforcement required to resist moment demand is designed. No other clauses are considered (no detailed layout).

D. French Concrete design per BAEL

RC Designer has two BAEL design briefs, the design principles utilized by these are defined in:

**Code Ref**  B.A.E.L. 91

**Description**  Regles techniques de conception et de calcul des ouvrages et constructions en beton armé suivant la méthode des états limites.

**Revision**  Deuxième tirage 1993

D. BAEL Beam Design Principles

The BAEL 91 Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to [D. Suitable Member Properties](on page 1006) for more details.

Beams are designed for flexure, and shear only. Each member is divided into equally spaced sections and the locations of maximum positive and negative moments along each element that makes up the member. The user can specify the number of segments to be considered between 4 and 25 for each member.

Design for Flexure

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment at that section.

The beam is then divided into sub-beams, those that can use the same cage

a. Same size
b. Same covers

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement is calculated for the range of bars specified in the Design Brief. The programs limits 8 bars in any one layer and uses a maximum of 2 layers.
The program then goes along the beam and checks each section to see how many bars from the critical sections can be removed. The bars are only removed at the section if they are not required for compression reinforcement or would result in failure in a crack check.

**Design for Shear**

The shear reinforcement is designed to resist the major axis shear force envelope, $F_z$, acting through the beam. The minor axis shear and torsional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, $v$, and concrete shear capacity, $v_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

![Figure 123: Minimum shear links required, V, for shear forces between these values](image)

**Anchorage and Bond Lengths**

Anchorage and bond lengths are calculated in accordance with the requirements of chapter 12. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table.

Reinforcement Property

Table 29 is used for minimum reinforcement ratio.

The Stress – Strain curve is assumed as straight.

The design Fy is calculated as $F_{y}/G_{s}$ (1.15 by default)

Bending calculation for Beam

Limiting Neutral Axis depth -> clause 8.2 & 8.3

For calculating limiting moment Fig. 25 being used

Partial safety factor is calculated using clause 5.3.3- Table 2 and 5.3.3.9

Table 9 used to setup all characteristic values for normal weight concrete

Design unconfined compressive strength is calculated as in 9.1.6.2

Steel Stress

Strain in steel is calculated as

$$(d – NA) \times E_{cu} / NA$$

where

$\begin{align*}
    d & \quad \text{Effective depth} \\
    NA & \quad \text{neutral axis depth} \\
    E_{cu} & \quad \text{obtained from table 9, } E_{c2u}^{*}.001
\end{align*}$$

Stress is calculated based on Figure 26 and 27

Reinforcement Calculation

Tension reinforcement

Reinforcement required = (Force) / (Steel Stress)

Fig. 25 is used to calculate the compressive force for a balanced section.

$A_{st, \text{required.}} = C / \text{Stress in steel}$

Compression reinforcement
If compression steel is required the steel stress in compression is calculated using the strain in the steel while in compression.

\[ \text{Ast, compression} = \frac{\text{(Extra Force)}}{\text{(Stress in steel in compression)}} \]

Additional Ast needs to be added for tension = \( \frac{\text{(Extra Force)}}{\text{(Steel Stress)}} \)

Reinforcement for Axial force

For axial force reinforcement required = \( \frac{\text{(Axial Force)}}{\text{(Steel Stress)}} \)

Total Ast = Tension reinforcement + Extra Ast for compression + Ast for Axial force

Reinforcement spacing

Reinforcement spacing is calculated according to clause 12.2.2

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, \( F_z \), acting through the beam. The minor axis shear and torsional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, \( v \), and concrete shear capacity, \( v_c \). From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

\[ V \]

\[ \text{zone 1 zone 2 zone 3 zone 4 zone 5 zone 6} \]

*Figure 124: Minimum shear links required, \( V \), for shear forces between these values*

Shear Reinforcement

Longitudinal reinforcement ratio is assumed as 0.02 as per 10.3.3.

\( \text{VRd,ct} \) is calculated using equation 70. (10.3.3)

\( \cot \theta \) is calculated using equation 72 (10.3.4)

\( \text{VRd,c} \) is calculated using equation 73 (10.3.4)

\[ z \text{ lever arm} = 0.9 \times \text{effective depth} \]

Minimum shear reinforcement is provided when design Shear Force < \( \text{VRd,ct} \)

Shear reinforcement is calculated using equation 75 when design shear force > \( \text{VRd,c} \)

Anchorage and Bond Lengths
Anchorage and bond lengths are calculated in accordance with the requirements of clause 3.12.8. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table.

D. DIN 1045-1 Column Design Principles
The DIN 1045 Column Design Brief is for prismatic, rectangular solid or circular shaped members. Members may be built up from multiple elements, but only the member end moments are considered, so only single height columns are recommended.

Design Principles
Columns are designed for axial force and biaxial end moments, as well as biaxial shear. Torsional moments are also included if specified in the design brief. Reinforcement is provided by the program based on the forces generated in the Analysis mode and the code clauses outlined below.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

All selected load combinations are used to calculate the required reinforcement. The combination which produces the maximum required reinforcement area is called the ‘Guiding Load Case’, and the bar arrangement is chosen based on that combination. Detailed printout of the design calculations is also for that combination.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

Check for slenderness
Slenderness is considered for both axis. A Column is considered if it satisfies 8.6.3.2
Critical slenderness is calculated as in 8.6.3.4

Calculation of design moment
Total eccentricity is calculated as in 8.6.5.5
e2, eccentricity is calculated as in 8.6.5.7

ea, the additional accidental eccentricity is calculated as in 8.6.4
The minimum eccentricity is calculated as in 8.6.3.9
For slender column e0, design first order eccentricity is in accordance with 8.6.5.6

Reinforcement limits
Maximum % of steel is calculated in accordance with 13.5.2.2
Minimum % of steel is calculated in accordance with 13.5.2.1

The shear reinforcement design in column is calculated in accordance with 10.3
The link spacing is in accordance with 13.5.3.4

D. Indian Concrete design per IS456
Concrete Design has two IS 456 design briefs, the design principles utilized by these are defined in:

<table>
<thead>
<tr>
<th>Code Ref</th>
<th>IS 456</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Plain and Reinforced Concrete - Code of Practice</td>
</tr>
</tbody>
</table>
D. IS456 General Considerations
This section describes some of the material properties, section properties, and other assumptions made for the
design of concrete beams and columns per IS456:2000 in RC Designer.

Materials
The following clauses from section 2 of IS 456:2000 are considered by the program:

- Cl 5.3.3 – The size of aggregate is considered as 20 mm.
- Cl. 5.6 – This implementation assumes that the reinforcement specified conforms to Cl. 5.6 of the code. The
  modulus of elasticity of the reinforcement is taken as 200,000 N/mm$^2$ as per clause 5.6.3 of the code.
- Cl. 6.2 – The program will only consider the design of elements that use ordinary concrete or Standard
  concrete.
  If you specify a high strength concrete grade (i.e., compressive strength greater than 55 N/mm$^2$), the
  program will issue a warning alert you that there might be additional considerations that need to be taken
  into account in the design. The design strengths of concrete shall be as given in Table 2 of IS 456:2000.
- Cl 6.2.2 – The tensile and flexural strength of concrete shall be taken as:
  \[
  f_{cr} = 0.7 \cdot \sqrt{f_{ck}}
  \]
  where:
  \[
  f_{ck} = \text{the characteristic compressive strength of concrete.}
  \]
- Cl. 6.2.3.1 – The modulus of elasticity of concrete is taken:
  \[
  E_c = 5000 \cdot \sqrt{f_{ck}}
  \]

Note: The effects of creep, shrinkage and thermal expansion are ignored.

General
This design is based on Limit state method. The Working Stress method in Annex B of IS 456:2000 is not
considered for this implementation. The loads and forces considered are as per Clause 19 and are defined in
STAAD.Pro. The density of concrete is taken as 24 KN/m$^3$. The stability of the structure as a whole (i.e.,
resistance to overturning, sliding, or lateral sway) are not considered by the program for the design of these
elements. This implementation assumes that the section dimensions comply with fire resistance according to
Clause 21 of the code.

The following clauses from section 3 of IS 456:2000 are considered by the program:

- Cl. 22.2 – The effective span for beams used is as defined in Cl. 22.2 (a) – (d) of the code. The clear span is
  taken as the node-to-node distance of a member (end nodes or supported nodes) in the STAAD.Pro model.
  Note: You will have the option to edit the effective length in the column (on page 1328) design brief.
- Cl. 22.3 – The relative stiffness for the members is based on the gross cross section where necessary. The
  design of the member is based on its gross cross section.
- Cl. 22.6.2 – The critical section for shear is considered to be at the face of the support. Enhanced shear at
  sections up to a distance equal to the effective depth of the beam are also considered.
- Cl. 23 – Refer to D. IS456 Beam Design Principles (on page 1057) for details of beam design.
- Cl. 25 – Refer to D. IS456 Column Design Principles (on page 1059) for details on column design
- Cl. 26 – Requirements for reinforcement and detailing:
Cl. 26.1.1 – The reinforcement provided in the design of beams is limited to four layers (i.e., two top & two bottom) for this implementation. Bundling of reinforcement will not be considered in this implementation.

26.1.2 – Consideration will also be given to the detailing rules as per IS 13920.

26.2.1 – The development length of bars is taken as:

\[ L_d = \frac{\varphi \cdot \sigma_s}{(4 \cdot \tau_{bd})} \]

where:

\( \varphi \) = nominal diameter of the bar
\( \sigma_s \) = stress in bar at the section considered at design load
\( \tau_{bd} \) = design bond stress given in 26.2.1.1

**Note:** Clause 26.2.1.1 gives the bond stress for bars in tension in the table. For bars in compression these values need to be increased by 25%. The anchorage length of straight bars in compression shall be in accordance with 26.2.1.

26.2.2.5 – The bearing stress at bends is considered and is evaluated as:

\[ \text{Bearing Stress} = \frac{F_{bt}}{(r \cdot \varphi)} \]

where:

\( F_{bt} \) = tensile force due to design loads in a bar or group of bars
\( r \) = internal radius of the bend
\( \varphi \) = size of bar or, in a bundle, the size of bar of equivalent area

The bearing stress within a bend or a hook should not exceed 1.5 \( F_{ck} / (1 + 2\varphi /a) \), where \( a \) is the center to center distance between bars.

Cl.26.2.3 - The curtailment of reinforcement shall be done as per the conditions given in cl. 26.2.3.1 to 26.2.3.4 of the code.

Cl.26.3 – The spacing of reinforcement shall be done as given in Cl.26.3.1 – 26.3.3 of the code.

Cl. 26.4 – The cover to reinforcement is specified by the user. However checks is done to make sure that the cover requirements as per Cl. 26.4.1 – 26.4.3 are met.

Cl.26.5 – The minimum reinforcement requirements as given in Cl. 26.5.1.1 is checked for beams and columns. Separate checks is done for tension, compression and side face reinforcements. Transverse reinforcements for beams will also be checked as per Cl. 26.5.1.4 - 26.5.1.8 of the code. The reinforcement requirements for columns is checked as per Cl. 26.5.3 of the code.

### Related Links
- D. IS456 Beam Design Brief dialog (on page 1325)
- D. IS456 Column Design Brief dialog (on page 1328)

**D. IS456 Beam Design Principles**

The IS456 Beam Design Brief is for single or multi span prismatic, rectangular members. The member sections must be setup in the Section Property Calculator and assigned from the User section database.

**Note:** Refer to the 'Section Property Calculator' manual for setting up standard sections and User databases.

Beams are designed for flexure and shear. Each member is divided into equally spaced sections and the locations of maximum positive and negative moments along each element that makes up the member. You may specify the number of segments to be considered between 4 and 25 for each member.
Both Ultimate limit state and Serviceability Limit states will be considered. Serviceability Limit states will be taken into account by satisfying the span/effective depth ratios specified in Cl. 23.2.1 of the code.

Partial Safety factors

The partial safety factors for materials used for member design are as follows:

\[ \Gamma_m \text{ for concrete} = 1.5 \]
\[ \Gamma_m \text{ for steel} = 1.15 \]

Design for Flexure

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Lateral bending are considered if this option is selected. Compression reinforcement is provided where required.

The design for flexure is performed as per Cl. 38 of the code.

The design of a beam is based on an envelope of design forces. Thus, at each of the defined sections the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment at that section.

The beam is then divided into sub-beams. The sub-beams which can use the same reinforcing cage are those with:

a. Same size
b. Same covers

For each sub-beam, the sections with the largest sagging and hogging moments are identified and the most efficient reinforcement is calculated for the range of bars specified in the Design Brief. The program is limited to eight bars in any one layer and uses a maximum of two layers.

The program then checks each section along the beam to determine how many bars from the critical sections can be removed. The bars are only removed at the section if they are not required for compression reinforcement or would result in failure in a crack check.

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, \( F_z \), acting through the beam. The minor axis shear and tensional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore, the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress \( \tau \) and concrete shear capacity \( \tau_c \). From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

The design for shear reinforcement is performed as per Cl.40 of the code. The nominal shear stress in beams is evaluated as:

\[ \tau = \frac{V}{bd} \]

where:

\[ V = \text{the shear force} \]
\[ b = \text{the width of the section taking the shear force} \]
\[ d = \text{the effective depth} \]
The design shear strength of concrete is taken as specified in Cl. 40.2 of the code. For members in axial compression, the design shear strength is multiplied by the following factor:

$$\delta = 1 + \frac{(3 \, P_u)}{(A_g \times f_{ck})}$$

where

- $P_u$ = the axial compressive load
- $A_g$ = the gross concrete area
- $f_{ck}$ = the characteristic compressive strength

Design for shear reinforcement is based on Cl.40.3 to 40.5 of the code. Note that the design brief includes the option of selecting whether to consider enhanced shear effects near the supports of the beam. If the option to consider enhanced shear is selected, the program also considers Cl.22.6.2 when working out the shear links.

Design for Torsion

The design of beams considers the combined effect of shear and torsion per Cl. B-6.3 of IS 456-2000. The design for torsion is based on Cl. 41.3 of IS 456. This method involves working out an equivalent bending moment and equivalent shear based on the torsional moment at a particular section. The equivalent shear force for torsion design is evaluated as:

$$V_e = V_u + 1.6 \frac{T_u}{b},$$

where

- $V_u$ = shear force at the section
- $T_u$ = torsional moment
- $b$ = the breadth of the beam

The longitudinal reinforcement required at a particular section subject to torsion is evaluated based on an equivalent bending moment evaluated as:

$$M_e = M_u + M_t$$

where

- $M_u$ = the bending moment at the cross section
- $M_t = T_u \{1+(D/b)\} / 1.7 \}$

The distribution of torsion reinforcement will then be done as per Cl. 26.5.1.7 of IS456.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore, the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress $\nu$ and concrete shear capacity, $\nu_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

Anchorage and Bond Lengths

Anchorage and bond lengths are calculated in accordance with the requirements of Cl. 26.2 of IS456:2000. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table and export to Multi-RC.

- [D. IS456 Column Design Brief dialog](on page 1328)

D. IS456 Column Design Principles

The IS456 Column Design Brief is for prismatic, rectangular solid, or circular shaped members.
As with Beam Design (on page 1057), section properties must be taken from the User databases. Members may be built up from multiple elements, but only the member end moments are considered, so only single height columns are recommended.

**Note:** Refer to the Section Property Calculator manual for setting up standard sections and User databases.

**Principles**

Columns are designed for axial force and biaxial end moments, Reinforcement is provided by the program based on the forces generated in the Analysis mode and the code clauses outlined below.

If the member has a reinforcement cage already defined, then the program checks the reinforcement for compliance. Otherwise the program will select a reinforcement cage from the bars and specifications of the Design Brief to minimize the area of main reinforcement bars.

**Tip:** Selecting a column member from the design group and selecting **Edit > Copy**, copies the reinforcement cage which can be pasted on columns in the Design Group of the same dimensions, which can then be checked with that same reinforcement.

All selected load combinations are used to calculate the required reinforcement. The combination which produces the maximum required reinforcement area is called the Guiding Load Case, and the bar arrangement is chosen based on that combination. Detailed printout of the design calculations is also for that combination.

The program conforms to the following requirements of section 39 of IS456: 2000 in the design module:

<table>
<thead>
<tr>
<th>Clause</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>39.2</td>
<td>Minimum Eccentricity</td>
</tr>
<tr>
<td>39.3</td>
<td>Short Axially Loaded member in compression</td>
</tr>
<tr>
<td>39.5</td>
<td>Members Subjected to Combined Axial Load and Uniaxial Bending.</td>
</tr>
<tr>
<td>39.6</td>
<td>Members Subjected to Combined Axial Load and Biaxial Bending.</td>
</tr>
<tr>
<td>39.7</td>
<td>Slender Compression Member</td>
</tr>
</tbody>
</table>

**Note:** Compression members with helical reinforcement (CL 39.4) are not considered by the program.

The design for compression members is based on Cl. 25 of IS456:2000. In addition to the assumptions made for beam design, the following assumptions are made for compression design:

- The maximum compressive strain in concrete in compression is 0.002
- When there is no tension in the concrete section and the section is subject to bending and axial compression, the maximum compressive strain at the highly compressed extreme fiber is taken as 0.0035 – 0.75 x strain in the least compressed extreme fiber.

Refer to the design brief (on page 1328) for an explanation of the input parameters.
All compression members are designed for a minimum eccentricity in accordance with Cl. 25.4 of IS456. Compression members are treated as either ‘short’ or ‘slender’ in accordance with Cl. 25.1.2 of IS456. A compression member will be considered as short when the slenderness ratios:

\[
l_{ex}/D < 12 \quad \text{and} \quad l_{ey}/b < 12
\]

where

\begin{align*}
l_{ex} &= \text{the effective length with respect to the major axis} \\
l_{ey} &= \text{the effective length with respect to the minor axis}
\end{align*}

If either of the slenderness ratios exceeds 12, the compression member is considered to be slender. The axial load capacity of a “short” compression member is calculated as per Cl. 39.3 of IS456. Compression members subject to combined axial load and bending must also satisfy the interaction equation as per Cl. 39.6 of IS456:2000. In the case of slender compression members, any additional moments are automatically calculated and used as per Cl. 39.7 of IS456. The correction factor ‘k’ used is also automatically calculated as per Cl. 39.7.1.1 of IS456.

The design procedure used involves an iterative process where the neutral axis position for the design section is evaluated for a given combination of axial force and/or bending moment. The bar arrangement is chosen based on the Guiding Load Case. The program systematically goes through all the bar sizes given in the brief to evaluate a symmetrical arrangement of bars on all four sides of the section. For each of the design sections thus considered, the program attempts to evaluate the neutral axis position for the given set of design forces. The program considers the neutral axis position from being at the extreme compressive fibers (edge of the section with the highest compressive force) up to a distance equal to four times the section depth. If the neutral axis depth is greater than 4 x D, the program classifies the chosen section as failed. Once the exact position on the neutral axis is determined, the program then evaluates the section moment capacities for the given axial load, about both axes. Subsequent interaction checks are also performed if necessary. Among all the design sections that are deemed satisfactory for the given set of forces, the program automatically selects the most efficient bar arrangement and reports the details. Upon determining a suitable main bar arrangement, the program then evaluates the required shear reinforcement for the section.

D. IS 13920 Seismic Design

Seismic checks per IS 13920:1993 can be performed with the concrete design module in STAAD.Pro (RC Designer). A valid IS456 beam and/or column design must be performed first in order to proceed with the seismic checks as per IS13920.

The following clauses are dealt with in the current version of the RC Designer:

Checks for beam members

In general, the following clauses from IS 13920 have been considered for beam design:

- Cl. 6.1.1 – The member will be checked to ensure that axial stress does not exceed 0.1 x fck (concrete strength)
- Cl. 6.1.2 & Cl. 6.1.3 – The program will issue a warning if the dimensions do not satisfy the limits in the code as per the clauses above.
- Cl. 6.1.4 – The program will issue a warning if the depth of the member exceeds ¼ of the span of the member.
- Cl. 6.2.1 & Cl. 6.2.2 – The longitudinal reinforcement ratios shall be checked as per the limits specified in the clauses above.
- Cl. 6.3 – The shear reinforcement shall be checked for a design shear force as specified in Cl. 6.3. of IS13920.

Checks for column members
In general, the following clauses from IS 13920 have been considered for column design:

Cl. 7.1.1 – The member will be checked to ensure that axial stress does not exceed 0.1 x fck (concrete strength)
Cl. 7.1.2 & 7.1.3 – The program will issue a warning if the dimensions do not satisfy the limits in the code as per the clauses above.
Cl. 7.3 – The program will work out the critical shear force as defined in Cl. 7.3.4 of the code.
Cl. 7.4 – The confining reinforcement (shear links) for the critical zones will be checked as per Cl. 7.4 of the code. The program will issue a pass/fail status for the shear links specified within the critical zones of the column. The Earthquake Reinforcement page (on page 1216) will indicate the status as 'pass' if the shear link spacing criteria of IS13920 are satisfied within the critical zones. Otherwise the program will indicate a 'fail' status.

- D. Designing longitudinal and shear reinforcement in beams per IS13920 (on page 1062)

D. Designing longitudinal and shear reinforcement in beams per IS13920

1. In the IS456 Beam Design Brief dialog General tab (on page 1325), set the Check for IS13920 option.
2. Perform a beam design.
3. Select the Earthquake page (on page 1216).
4. Select the appropriate load case is selected to perform the seismic checks to allow for a strong column-weak beam mechanism.

The program internally calculates the moment capacities of the beams and columns framing into a joint and assign a 'pass/fail' status depending on the corresponding beam and column capacities at that joint for the direction under consideration. If the sum of the column capacities is greater than the sum of the beam capacities in a particular direction, the program will assign a 'pass' status. If on the other hand, the sum of the column capacities is greater than the beam capacities, the program will assign a 'fail' status. The program will also check for the shear reinforcement capacities and shear link spacings in the "critical zones" as defined in IS13920.

5. Select the Earthquake Reinforcement page to review the status of the IS 13920 design.

D. Japanese Concrete design per AIJ

RC Designer has one AIJ design brief, the design principles utilized by this is defined in:

<table>
<thead>
<tr>
<th>Code Ref</th>
<th>Description</th>
<th>Revision</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIJ</td>
<td>Standard for structural calculation of reinforced concrete structures</td>
<td>1985</td>
</tr>
</tbody>
</table>

D. AIJ Beam Design Principles
The AIJ Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to D. Suitable Member Properties (on page 1006) for more details.
Beams are designed for flexure, and shear only. Each member is divided into equally spaced sections and the locations of maximum positive and negative moments along each element that makes up the member. The user can specify the number of segments to be considered between 4 and 25 for each member.

Design for Flexure

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment at that section.

The beam is then divided into sub-beams, those that can use the same cage

**a.** Same size  
**b.** Same covers

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement is calculated for the range of bars specified in the Design Brief. The programs limits 8 bars in any one layer and uses a maximum of 2 layers.

The program then goes along the beam and checks each section to see how many bars from the critical sections can be removed. The bars are only removed at the section if they are not required for compression reinforcement or would result in failure in a crack check.

Design procedure

**Fy** – allowable unit stress for reinforcement bars is calculated based on Table 5 and considers both temporary and permanent loading

2. Calculate Neutral axis ratio based on Art. 14, equation 8.

Allowable bending moment = \(Cbd^2\)

Gamma is considered to be 0.4 to begin with for light weight concrete.

The area of reinforcement, \(A_t\), is calculated using Art. 14.3, equation 14 when the allowable bending moment is greater than the design moment.

An iterative method is used to calculate area of reinforcement required when design moment is greater than allowable moment.
1. First program tries to increment compression reinforcement by incrementing gamma.
2. If gamma reaches 1.0, then program increments tension reinforcement and recalculates “C”.
3. The design fails if the tension reinforcement exceeds maximum reinforcement.

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, Fz, acting through the beam. The minor axis shear and torsional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, \( v \), and concrete shear capacity, \( v_c \). From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

![Figure 125: Minimum shear links required, V, for shear forces between these values](image)

Shear capacity is calculated in accordance with Art. 16.2.1, equation 22

\[ f_s \] is calculated in accordance with table 4.

To calculate ‘pw’, spacing is first assumed to be 45 cm. and the program runs through a iterative method and reduces the spacing to establish the actual required spacing.

The design checks for minimum and maximum spacing as per Art.16.4.ii

Anchorage and Bond Lengths

Anchorage and bond lengths are calculated in accordance with the requirements of chapter 12. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table.

D. NS3473 Column Design Principles

The NS 3473 Column Design Brief is for prismatic, rectangular solid or circular shaped members. Members may be built up from multiple elements, but only the member end moments are considered, so only single height columns are recommended.

**Design Principles**

Columns are designed for axial force and biaxial end moments, as well as biaxial shear. Torsional moments are also included if specified in the design brief. Reinforcement is provided by the program based on the forces generated in the Analysis mode and the code clauses outlined below.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

All selected load combinations are used to calculate the required reinforcement. The combination which produces the maximum required reinforcement area is called the 'Guiding Load Case', and the bar arrangement is chosen based on that combination. Detailed printout of the design calculations is also for that combination.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

**D. Russian Concrete design per SP 52-101-03**

RC Designer has two SP 53-101-03 design briefs, the design principles utilized by these are defined in:
Design
D. Concrete Design

Code Ref  SP 52-101-2003
Description "Concrete And Reinforced Concrete Structures Without Prestressing," Concrete and Reinforced Concrete Research and Technological Institute (НИИЖБ)
Revision  2006

D. SP52-101-03 Beam Design Principles
Design of the multi-span reinforced concrete beam is performed according to the Russian design code SP52-101-2003 Concrete And Reinforced Concrete Structures Without Prestressing, 2004. The program computes required reinforcement areas and performs necessary RC detailing operations. The ultimate limit state and serviceability limit state verification as well as detailing requirements of the SP52-101-2003 are provided in this program.

Present Russian RC design code, SP52-101-2003 Concrete And Reinforced Concrete Structures Without Prestressing, coincides with 1990 CEB – FIB Model Code for Concrete Structures in the part of normal section analysis. However, shear and torsion analysis and cracking calculations are based on rather different principles.

Design for Bending
Analytical model for planar bending is based on the following figure:

![Figure 127: Planar bending of RC section](image)

where

- \( R_b \) = design strength of concrete
- \( R_s \) = design strength of steel
- \( x \) = depth of neutral axis, constrained by the limiting quantity, depending on steel strength

In the program the small value of the axial force can be taken into account, provided the compression force does not cause the neutral axis depth greater than the limiting value, and in the tension case, the hog zone remains compressed.
The bending strength of the section and the layout of the longitudinal reinforcing steel are interrelated through the effective depth of the section. The crack width limitation must also be taken into account when choosing the longitudinal reinforcement. On the other hand, one must try all possible load combinations having in mind the interaction of the axial force and bending moment.

Strength and crack width verification is performed for the set of design sections uniformly spaced in a span. The user can introduce additional checking points for each span where he presumes the existence of the sharp maximum of the moment caused by the concentrated force. The critical load combination is defined by the maximum value of the required tension steel area for each design section. The sag- and hog-critical sections are defined by the maximum of required tension reinforcement. The layout of tension steel bars is defined for both sag- and hog-critical section of the beam.

All admissible bar diameters are tried during design of critical section; the diameter resulting in minimum steel area is adopted as optimal one. As the result, the optimum layout for critical sag reinforcement and critical hog reinforcement is obtained.

The tension bar layouts are produced only for critical sections. For other design sections, the bar layouts are obtained during bar curtailment procedure as illustrated in the following figure. Required steel areas, computed previously, are used during this procedure.

The use of this design method is restricted to beams with predominantly downward-directed loads, when maximum sag moments are located in about the middle of span and maximum hog moments (if any) are at the supports. In this case the provided steel areas at all design sections are straightforwardly obtained in the sequential bars curtailment procedure.
Design for Shear

It is assumed that the shear resistance of member consists of the following two factors:

- concrete compression zone shear $Q_b$
- contribution of links $Q_{SW}$

The contribution of inclined reinforcing steel is not considered.

![Figure 129: Shearing of RC member](image)

The following formula is used to calculate crack width:

$$a_{cr} = \varphi_1 \varphi_2 \psi_s (\sigma_s / E_s) l_s$$

where

- $\sigma_s$ = steel stress computed according to elastic formulas, excluding concrete tension zone
- $l_s$ = spacing of cracks
- $\varphi_1$ = 1.0 for short term loading, = 1.4 for long term loading
- $\varphi_2$ = 0.5 for high bond bars, = 0.8 for bars with plain surface
- $\psi_s$ = factor allowing for steel-concrete interaction in the tension zone $\leq 1.0$,

The spacing of cracks is calculated from the expression

$$l_s = 0.5(A_{bt}/A_S) d_s$$

where

- $A_{bt}$ = concrete tension area
- $A_S$ = steel tension area
- $d_s$ = diameter of reinforcing bars

The torsional strength includes the contributions of both the longitudinal and transverse reinforcement.

The longitudinal reinforcement is checked according to strength and crack width conditions. The transverse bars must comply with the inclined sections strength and maximum allowable spacing conditions. Additionally, in the presence of torsion moments the combined action of bending, shear and torsion must be taken into account.

Design Procedure

The design process is summarized by the following steps:
1. Find the sag- and hog-critical sections of the continuous beam, according to the maximum required tension steel area. Typically, these sections are situated at a support and at about the middle of a span.

2. Produce the layouts of tension reinforcing steel for these two critical sections.

3. Produce the derived layouts for all supports and most adverse middle span sections of each beam.

4. Carry out the reinforcing steel curtailment procedure for each span of the continuous beam.

5. Compute the required stirrup spacing for each section of the continuous beam. In the detailing procedure, the stirrup spacing may be manually defined for each part of the span.

6. The final strength check is performed for the obtained layout for each design section.

The assumptions adopted for the beam design procedure, can be summarized as follows:

1. The diameters of bottom and top reinforcing bars may be different; all bars in the bottom or top of the continuous beam are of the same diameter.
2. The sag- and hog-critical sections of the continuous beam are selected according to the most adverse load conditions; basic reinforcement layouts are produced for these two critical sections.
3. The diameters of the bars for the sag- and hog-critical reinforcement are chosen according to the minimum steel area criterion, within the reasonable boundaries you have imposed.
4. The tension bars compatibility is retained at support sections of the continuous beam. The sag bars layouts and diameters in each span can be different.
5. In each span of the continuous beam the derived layouts, compatible with the basic layouts, are to be produced.
6. Derived layouts are based on the same reinforcing bar diameters as basic ones.
7. Bar curtailment is based on the loading and strength conditions of the set of the beam cross-sections; these cross-sections must not coincide with definite nodes of the finite element mesh.

Eccentrically Loaded Columns

The strength of the section and the layout of the longitudinal reinforcing steel bars are interrelated through the effective depth of the section. The program evaluates all selected load combinations in the envelope to determine the worst case interaction of the axial force and bending moment.

Strength verification is performed for the section with maximum axial force eccentricity. The critical load combination is defined by the maximum value of the required steel area. All admissible bar diameters are tried during design of critical section. The diameter resulting in minimum steel area is adopted as optimal one. The transverse reinforcement is determined using maximum shear force value.
**Design Procedure**

The design process is summarized by the following steps:

1. For each load combination, find the critical section of the column, according to the maximum axial force eccentricity.
2. Design the reinforcing steel for the critical section.
3. Compute the required stirrup spacing for the column.
4. Perform the final strength check for the obtained longitudinal and transverse reinforcement.

The assumptions adopted for the column design procedure, can be summarized as follows:

1. The longitudinal reinforcement of the column is symmetrical.
2. Diameter of the intermediate longitudinal bars in the section can be less than that of the corner bars.

**D. Singaporean Concrete design per CP65**

Concrete Design has two CP 65 design briefs, the design principles utilized by these are defined in:
D. CP65 Beam Design Principles

The CP 65 Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to D. Suitable Member Properties (on page 1006) for more details.

Beams are designed for flexure, and shear only. Each member is divided into equally spaced sections and the locations of maximum positive and negative moments along each element that makes up the member. The user can specify the number of segments to be considered between 4 and 25 for each member.

Design for Flexure

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment at that section.

The beam is then divided into sub-beams, those that can use the same cage

- Same size
- Same covers

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement is calculated for the range of bars specified in the Design Brief. The programs limits 8 bars in any one layer and uses a maximum of 2 layers.

The program then goes along the beam and checks each section to see how many bars from the critical sections can be removed. The bars are only removed at the section if they are not required for compression reinforcement or would result in failure in a crack check.
Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, $F_z$, acting through the beam. The minor axis shear and torsional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, $\nu$, and concrete shear capacity, $\nu_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

![Figure 131: Minimum shear links required, V, for shear forces between these values](image)

Anchorage and Bond Lengths

Anchorage and bond lengths are calculated in accordance with the requirements of clause 3.12.8. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table.

Code Clauses Implemented

**Design Principles**

Columns are designed for axial force and biaxial end moments, as well as biaxial shear. Torsional moments are also included if specified in the design brief. Reinforcement is provided by the program based on the forces generated in the Analysis mode and the code clauses outlined below.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

All selected load combinations are used to calculate the required reinforcement. The combination which produces the maximum required reinforcement area is called the “Guiding Load Case”, and the bar arrangement is chosen based on that combination. Detailed printout of the design calculations is also for that combination.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

D. Turkish Concrete design per TS 500

Concrete Design has two TS 500 design briefs, the design principles utilized by these are defined in:

<table>
<thead>
<tr>
<th>Code Ref</th>
<th>TS 500</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Building code requirements for reinforced concrete by the Turkish 'TS 500' code.</td>
</tr>
<tr>
<td>Revision</td>
<td>February 2000</td>
</tr>
</tbody>
</table>

**Note:** The TS-500 code is very much influenced by the ACI-318 design code; many of the formulas and requirements are exactly the same, with certain differences in constants and properties.

D. TS 500 Beam Design Principles

The TS 500 Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to [D. Suitable Member Properties](on page 1006) for more details.

Beams are designed for flexure, and shear only. Each member is divided into equally spaced sections and the locations of maximum positive and negative moments along each element that makes up the member. The user can specify the number of segments to be considered between 4 and 25 for each member.

**Design for Flexure**

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment at that section.

The beam is then divided into sub-beams, those that can use the same cage

a. Same size
b. Same covers

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement is calculated for the range of bars specified in the Design Brief. The programs limits 8 bars in any one layer and uses a maximum of 2 layers.
The program then goes along the beam and checks each section to see how many bars from the critical sections can be removed. The bars are only removed at the section if they are not required for compression reinforcement or would result in failure in a crack check.

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, \( F_z \), acting through the beam. The minor axis shear and torsional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, \( v \), and concrete shear capacity, \( v_c \). From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

![Diagram of shear links](image)

**Figure 133: Minimum shear links required, \( V \), for shear forces between these values**

Design for Torsion

If the option to 'Include Torsion Effects' is selected in the Beam Design Brief - General. Then the design is modified by using:

\[
V_{cr} = 0.65f_{cd}b_w d \\
T_{cr} = 1.35f_{cd}T_S
\]

(Eqn. 8.11)

where

- \( T_{cr} \) = torsional moment that causes torsional cracking
- \( S \) = sectional constant

TS-500 uses a simplified \( S \) in the calculations.

\[
\psi = \left( \frac{V_d}{V_{cr}} \right)^2 + \left( \frac{T_d}{T_{cr}} \right)^2
\]

where

- \( V_d \) and \( T_d \) = the computed shear and torsional values
- \( > V_{cr} \) and \( > T_{cr} \) = are the cracked section shear and torsion values

If this is less than 1.0 then the section is classed as 'not cracked', but minimum reinforcement should be provided.

If it is greater or equal to 1.0 then it is classed as cracked and the torsional stress must be checked. If this stress is greater than 0.25 \( f_{cd} \), then the cross section is inadequate and the section must be increased.
S is calculated according to its shape thus:

<table>
<thead>
<tr>
<th>Shape</th>
<th>Section Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rectangular</td>
<td>( b_w \frac{y}{h} )</td>
</tr>
<tr>
<td>Tee</td>
<td>( \Sigma \left( x^2 \frac{y}{h} \right) )</td>
</tr>
<tr>
<td>Circular</td>
<td>( \pi \frac{d^3}{12} )</td>
</tr>
</tbody>
</table>

where 'x' and 'y' = the short and long edges respectively for the rectangles that form the Tee section.

The maximum Torsional stress is calculated from:

\[ \tau_{\text{max}} = 0.22 f_{\text{cd}} \]

The actual torsional stress is calculated as:

\[ \tau = \tau_{s0} + \tau_{to} \]

or

\[ \tau = \frac{V_d}{b_w d} + \frac{T_d}{S} \]

which must be less than or equal to 0.22 \( f_{\text{cd}} \) (equation 8.19).

The recommendation for torsional reinforcement is:

a. Longitudinal torsional reinforcement should be placed around the section perimeter and must be at least 12 mm diameter, with the maximum spacing of 30 cm.

b. Link bars should be at least 8 mm diameter.

c. The maximum link spacing should be the minimum of \( d/2 \), \( ue/8 \) and 30 cm.

d. Torsion requires greater anchorage. Use minimum 10 diameter length as free end for hook

Anchorage and Bond Lengths

Anchorage and bond lengths are calculated in accordance with the requirements of chapter 12. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table.

<tr>
<td></td>
<td>Part 2:1985 (used for torsion design)</td>
</tr>
</tbody>
</table>

**D. BS8110 Beam Design Principles**

The BS8110 Beam Design Brief is for single or multi span, prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to *D. Suitable Member Properties* (on page 1006) for more details.

Beams are designed for bending, shear and deflection. They may also be checked for Torsion. Sections are taken at equal increments along each span of the beam and at the positions of maxima of hogging and sagging moments and maximum positive and negative shear.

**Design for Bending**

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment at that section.

The beam is then divided into sub-beams, those that can use the same cage

- **a.** Same size
- **b.** Same covers
For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement is calculated for the range of bars specified in the Design Brief. The program's limits design to 8 bars in any one layer and uses a maximum of 2 layers in each face.

The program then goes along the beam and checks each section to see how many bars from the critical sections can be removed. The bars are only removed at the section if they are not required for compression reinforcement or would result in failure in a crack check.

Design for Shear

The shear reinforcement is designed to resist the major axis shear force envelope, $F_z$, acting through the beam. The minor axis shear and torsional forces are not considered.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, $v$, and concrete shear capacity, $v_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.

Design for Torsion

The method for designing a beam with a rectangular section to resist torsion is as follows. It consists of calculations to determine an additional area of longitudinal and link reinforcement required to resist the torsional shear forces.

1. Determine $A_s$ and $A_{sv}$ to resist the bending moments and shear forces by the usual procedures.
2. Calculate the torsional shear stress (for rectangular) clause 2.4.4.1

\[ v_t = \frac{2T}{h_{\min} \left( h_{\max} - h_{\min} / 3 \right)} \]

where

\[ T = \text{torsional moment due to the ultimate loads} \]
\[ h_{\min} = \text{the smaller dimension of the beam section} \]
\[ h_{\max} = \text{the larger dimension of the beam section} \]

3. If \( v_t > v_{t\text{min}} \) in table 2.3, then torsional reinforcement is required. Refer table 2.4 for the reinforcement requirements with a combination of torsion and shear stress \( v \).

- but not more than 0.4 N/mm\(^2\)
- but not more than 5 N/mm\(^2\)

**Table 81: Table 2.4 Reinforcement for shear and torsion**

<table>
<thead>
<tr>
<th>( vt \leq v_{t\text{min}} )</th>
<th>( vt &gt; v_{t\text{min}} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( v \leq v_c + 0.4 )</td>
<td>Minimum shear reinforcement; no torsion reinforcement</td>
</tr>
<tr>
<td>( v &gt; v_c + 0.4 )</td>
<td>Designed shear reinforcement; no torsion reinforcement</td>
</tr>
</tbody>
</table>

4. Calculate the additional shear reinforcement required from torsion (as per clause 2.4.7)

\[ S_v < 200 \text{ mm or } x_1 \]

Where \( x_1 \) is smaller center-to-center dimension of a link.

\( y_1 \) is larger center-to-center dimension of a link.

5. Calculate the additional area of longitudinal steel. (as per clause 2.4.7)

For beams formed from Tee and L shaped profiles, each cross section is divided into rectangles so that the stiffness is maximized as defined in clause 2.4.4.2. The rectangle with the largest \( h_{\text{min}}^3 \cdot h_{\text{max}} \) is then checked to ensure that the torsional shear stress does not exceed the limits and the maximum link spacing is based on this rectangle.

**Anchorages and Bond Lengths**

Anchorages and bond lengths are calculated in accordance with the requirements of clause 3.12.8. They can be displayed graphically on the Main Reinforcement diagram and are used for the schedule table and export to Multi-RC.

Code Clauses Implemented

The following lists the code clauses used from BS 8110 Part 1:1997.

3.8 Column

3.8.1 General. Program Conforms
3.8.1.1 Symbols. Program Conforms
3.8.1.2 Size of columns. N/A
3.8.1.3 Short and slender columns. Program Conforms
3.8.1.4 Plain concrete columns. N/A
3.8.1.5 Braced and unbraced columns. Program Conforms

3.8.1.6 Effective height of a column

3.8.1.6.1 General. Program Conforms with Beta as a user input
3.8.1.6.2 End conditions. Program Conforms with Beta as a user input
3.8.1.7 Slenderness limits for columns. Program conforms
3.8.1.8 Slenderness of unbraced columns. Program conforms

3.8.2 Moments and forces in columns

3.8.2.1 Columns in monolithic frames designed to resist lateral forces. User decision
3.8.2.2 Additional forces induced by deflection at ULS. Program Conforms for column being designed, not for members connected
3.8.2.3 Columns in column and beam construction or in monolithic braced structural frames. Forces to be designed for are determined by the user's own model.
3.8.2.4 Minimum eccentricity. Program conforms

3.8.3 Deflection induced moments in solid slender columns

3.8.3.1 Design
3.8.3.2 Design moments in braced columns bent about a single axis. Program Conforms
3.8.3.3 Slender columns bend about a single axis (major or minor). Program Conforms
3.8.3.4 Columns where le/h exceeds 29, bent about their major axis. Program Conforms
3.8.3.5 Columns bent about their major axis. Program Conforms
3.8.3.6 Slender columns bent about both both axes. Program Conforms
3.8.3.7 Unbraced structures. Program Conforms
3.8.3.8 Deflection of unbraced column. N/A
3.8.3.9 Additional moments on members attached to a slender column. N/A

3.8.4 Design of column section for ULS

3.8.4.1 Analysis of sections. Program Conforms
3.8.4.2 Design charts for symmetrically-reinforced columns. N/A
3.8.4.3 Nominal eccentricity of short columns resisting moments and axial loads. N/A
3.8.4.4 Short braced columns supporting an approximately symmetrical arrangement of beams. N/A
3.8.4.5 Biaxial bending. Program Conforms
3.8.4.6 Shear in columns. Program Conforms
3.8.5 Deflection of columns. N/A
3.8.6 Crack control in columns. The clause states that “if crack check is required, then the member should be checked as a beam”

N/A is to be interpreted as either not application or not implemented.

Clauses that do not appear in the list are deemed not to be considered by the program.

- D. BS 8110 Beam Design Brief dialog (on page 1255)
- D. BS 8110 Column Design Brief dialog (on page 1257)
- D. BS8110 Slab Design Brief dialog (on page 1260)

D. BS8110 Slab Design Principles

The BS8110 Slab Design Brief is for any slab modeled with F.E. regardless of boundary restrained conditions.

Slabs are designed for flexure in two orthogonal directions for both hogging and sagging moments. It does not include design for shear or punching shear checks.

Analysis results for plate elements that form a 'Slab' are used to generate design moments with respect to the axis of the slab. These moments are then used to generate required reinforcement contours. An option if available in the slab design brief to use moment theory developed by Wood an Armer ("The Theory of the Strip Method for Design of Slabs” Proceedings, Institution of Civil Engineers, London; Vol. 41, October 1968, pp. 285-313).

The level of accuracy of results depends on the meshing density used to model the slabs. It is recommended that you examine the accuracy of the model at the analysis stage and ensure satisfactory results are obtained prior to the design stage.

Design for Flexure

Longitudinal and transverse reinforcement are calculated for both sagging and hogging moments on the basis of the slab thickness and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a slab is based on an envelope of design forces and thus at each element center, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment in the two orthogonal directions (i.e., Slab/Region local axis).

Reinforcement calculation is based on the BS8110 recommendations for the design of rectangular beams assuming a unit meter width together with the elements thickness.

Slab end restrained conditions are not catered for at the design stage, however to ensure accuracy of design results, they must be incorporated in the analytical model of the structure.
Design
D. Concrete Design

Note: The program does not perform shear checks per BS 8110.

**D. American Concrete design per ACI 318 - 1999**

RC Designer has two ACI 318 - 1999 design briefs, the design principles utilized by these are defined in:

<table>
<thead>
<tr>
<th>Code Ref</th>
<th>Description</th>
<th>Revision</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACI 318-99</td>
<td>Building Code Requirements for Structural Concrete (ACI 318-99) and Commentary (ACI 318R-99)</td>
<td>Second printing, February 1996</td>
</tr>
</tbody>
</table>

D. ACI 318 - 99 Beam Design Principles

The ACI 318-99 Beam Design Brief is for single or multi span prismatic, rectangular solid or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to D. Suitable Member Properties (on page 1006) for more details.

Beams are designed for flexure, shear and torsion. Each member is divided into equally spaced sections along its length and the design is performed at each of these locations. The user can specify the number of segments to be considered (between 4 and 25) for each span. Sections are also taken at face of supports and at locations of the maximum positive and negative bending moments.

**Design for Flexure**

The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of the design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment values from the analysis.

The beam is then divided into sub-beams, those that can use the same reinforcement cage and having

a. Same overall beam size
b. Same cover requirements

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement pattern is calculated for the range of bars specified in the Design Brief. The program does not have a limit on the number of bars in any one layer as long as the spacing requirements specified in the code are satisfied. The program can handle a maximum of 4 layers of reinforcement, two each for the top and bottom layers.
The program then performs a check at each of the defined sections to determine the number of bars, if any, that can be curtailed. The reinforcement bars will not be curtailed at these sections in the following cases:

a. If the bars are required for compression or
b. If curtailling these bars would result in a failure of crack-width checks or
c. If curtailling these bars would result in a failure of the minimum reinforcement checks.

Design for Shear and Torsion

Stirrups are designed to resist the major axis shear force envelope, Fz, and optionally the torsional moments induced in the beam. The minor axis shear forces and torsional moments are not considered in the design.

The bar size for shear stirrups and the minimum number of shear legs to be provided are specified in the Design Brief. Therefore the required spacing for minimum stirrups can be defined. The program then checks each section to determine the shear stress, \( v \), and concrete shear capacity, \( v_c \). From this, the section is classified as either ‘minimum stirrup’ or a ‘high shear’ section. Adjacent sections of the same type are grouped into zones. For non minimum stirrup zones, the shear stirrups are designed for the maximum shear force within that zone.

If torsion is to be considered, the program checks whether the threshold torsion has been exceeded at each section and if so determines the corresponding reinforcement required and then adds this to the requirements for shear.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, \( v \), and concrete shear capacity, \( v_c \). From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.
Anchorage and Bond Lengths
Anchorage and bond lengths are calculated in accordance with the requirements of chapter 12. They can be displayed graphically on the main reinforcement diagram and are used for the schedule table.

Notes:
The following settings should be checked in the design brief:

- β d factor.
- whether or not there is transverse loading.
- stability index Q (must be > 0.05 and ≤ 0.6).
- load case number that causes appreciable sidesway. If columns require different loadcases for sidesway, then they should be designed in separate design groups.
- β factor for biaxial bending (default 0.65).

D. American Concrete design per ACI 318 - 2005
RC Designer has three ACI 318 - 2005 design briefs, the design principles utilized by these are defined in:

**Code Ref**  ACI 318-2005

**Description**  Building Code Requirements for Structural Concrete (ACI 318-05) and Commentary (ACI 318R-05)

**Revision**  First printing, December 2004

**Note:** [Metric](on page 1105) is available for use with ACI 318M-05 in STAAD.Pro V8i (SELECTseries 2) 20.07.07 and higher.

D. ACI 318-05 Beam Design Principles
The ACI 318-05 Beam Design Brief is for single or multi-span prismatic, rectangular solid, or tee shaped members. The member sections must be defined as PRISMATIC sections in the STAAD.Pro data file.

Refer to [D. Suitable Member Properties](on page 1006) for more details.

Beams are designed for flexure, shear and torsion. Each member is divided into equally spaced sections along its length and the design is performed at each of these locations. The user can specify the number of segments to be considered (between 4 and 25) for each span. Sections are also taken at face of supports and at locations of the maximum positive and negative bending moments.

**Design for Flexure**
The main (longitudinal) reinforcement is calculated for both sagging and hogging moments on the basis of the section profile and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a beam is based on an envelope of the design forces and thus at each of the defined sections, the program determines the required area of steel for both the maximum hogging moment and maximum sagging moment values from the analysis.

The beam is then divided into sub-beams, those that can use the same reinforcement cage and having

- a. Same overall beam size
- b. Same cover requirements

For each sub-beam, the sections that have the largest sagging and hogging moments are identified and the most efficient reinforcement pattern is calculated for the range of bars specified in the Design Brief. The program
The program then performs a check at each of the defined sections to determine the number of bars, if any, that can be curtailed. The reinforcement bars will not be curtailed at these sections in the following cases:

- If the bars are required for compression
- If curtailing these bars would result in a failure of crack-width checks
- If curtailing these bars would result in a failure of the minimum reinforcement checks.

**Design for Shear and Torsion**

Stirrups are designed to resist the major axis shear force envelope, $F_z$, and optionally the torsional moments induced in the beam. The minor axis shear forces are not considered in the design.

The bar size for shear stirrups and the minimum number of shear legs to be provided are specified in the Design Brief. Therefore the required spacing for minimum stirrups can be defined. The program then checks each section to determine the shear force $V_n$ and concrete shear capacity $V_c$. From this, the section is classified as either 'minimum stirrup' or a 'high shear' section. Adjacent sections of the same type are grouped into zones. For non minimum stirrup zones, the shear stirrups are designed for the maximum shear force within that zone.

If torsion is to be considered, the program checks whether the threshold torsion has been exceeded at each section and if so determines the corresponding reinforcement required and then adds this to the requirements for shear.

The number of shear legs and the shear link size is specified in the Design Brief. Therefore the required spacing for minimum links can be defined. The program then checks each section to determine the shear stress, $v$, and concrete shear capacity, $v_c$. From this, the section is classified as either minimum link or a high shear section. Adjacent sections of the same type are grouped into zones. For non minimum link zones, the shear links are designed for the maximum shear force within that zone.

If necessary, additional legs may be added to the shear links in order to restrain tension or compression reinforcement.
Development Lengths

Development lengths are calculated in accordance with the requirements of chapter 12. They can be displayed graphically on the main reinforcement diagram and are used for the schedule table and export to rebar detailing programs.

D. ACI 318-05 Column Design Principles
The ACI 318-05 Column Design Brief is for prismatic, solid rectangular or circular shaped members. Members may be built up from multiple elements, but only the member end moments are considered. Hence only single height columns are recommended.

Design Principles
Columns are designed for axial force and biaxial end moments, as well as biaxial shear. Torsional moments are also included if specified in the design brief. Reinforcement is provided by the program based on the forces generated from the analysis model and the code clauses outlined below.

The main reinforcing bars may be modified to allow for other bars passing through the section and then re-checked to ensure that the design requirements are satisfied.

All selected load combinations are used to calculate the required reinforcement. The combination which produces the maximum required reinforcement area is called the 'Guiding Load Case', and the bar arrangement is chosen based on that combination. Detailed printout of the design calculations provided is for that combination.

Code Clauses Implemented

- [D. ACI 318-05 and 318M-05 Beam Brief dialog](on page 1224)

D. ACI 3 18-05 Slab Design Principles

The ACI 3 18-05 Slab Design Brief is for any slab modeled with finite elements regardless of boundary restraint conditions.

Slabs are designed for flexure in two orthogonal directions for both hogging and sagging moments. Designs for shear or punching shear checks are not included.

Analysis results for plate elements that form a 'Slab' are used to generate design moments with respect to the axes of the slab. These moments are then used to generate required reinforcement contours. Note that no account is taken of the requirements for embedment or development of reinforcement.

**Tip:** The level of accuracy of results depends on the meshing density used to model the slabs. It is recommended that users examine the accuracy of the model at the analysis stage and ensure satisfactory results are obtained prior to the design stage.

**Design for Flexure**

Longitudinal and transverse reinforcement are calculated for both sagging and hogging moments on the basis of the slab thickness and parameters defined in the Design Brief. Compression reinforcement is provided where required.

The design of a slab is based on an envelope of design forces. Hence the program determines the required area of steel at the center of each element, for both the maximum hogging and sagging moments in the two orthogonal directions. (i.e., along the Slab/Region local axes)

Reinforcement calculation is based on the ACI 318-05 recommendations for the design of one-way slab systems assuming a unit width together with the elements thickness.

Slab end restraint conditions are not catered for at the design stage, however to ensure accuracy of design results, they must be incorporated in the analytical model of the structure.

As has been stated earlier, in this release of the RC designer, shear checks have not been catered for.

**Code Clauses Implemented**

The list of code clauses used from ACI 318-05 is as follows:

Chapter 3 - Materials

3.3.2 (c)
Chapter 7 - Details of Reinforcement

7.6.1
7.6.5
7.12.2.1

Chapter 9 - Strength and Serviceability Requirements

9.1.1
9.3.1
9.3.2.1 – Sections are assumed to be tension controlled

Chapter 10 - Flexure and Axial Loads

10.2.2 but not deep flexural members
10.2.3
10.2.4
10.2.7
10.5.4 – but with spacing not greater than twice the slab thickness (assumes two-way slab as 13.2.2)
10.6.4

Chapter 13 – Two Way Slab Systems

13.2.2

D. American Concrete design per ACI 318M - 2005

RC Designer has three ACI 318M - 2005 design briefs, the design principles utilized by these are defined in:

Note: This feature is available in STAAD.Pro V8i (SELECTseries 2) release 20.07.07 and higher.

Code Ref ACI 318M-2005
Description Metric Building Code Requirements for Structural Concrete (ACI 318M-05) and Commentary (ACI 318R-05)
Revision First printing, January 2005

See D. American Concrete design per ACI 318 - 2005 (on page 1096) for information on the implementation of ACI 318-05.

D. Earthquake Collapse Check

This checks at each column / beam interface, the program checks that the capacity of the column exceeds the total capacity of all beams that connect to it.

The earthquake check only uses the results from Design Groups that have Design Briefs from the selected Design Code.
D. Application Window Layout

This section documents all aspects of the Concrete Design program interface.

The application window contains the following special sections by default:

A. **Menus** (on page 1106)
B. **Standard toolbar** (on page 1193)
C. **Page/Mode Automatic toolbar** (on page 1195)
D. **Page Control** (on page 1202)
E. **View Window** (on page 1014)
F. **Status Bar** (on page 1217)

---

D. Menus

These are the commands that are available from the menus.

**Note:** The menus and items change depending on the mode and the type of current window (e.g., Graphic or Table).
D. File menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>

<td></td>
</tr>
</tbody>
</table>

**Note:** Before using this command, install and select a printer. For more information refer to the Windows documentation.

The appearance and content of the Concrete Design report can be configured using **File > Report Setup**. The Printer settings are modified by selecting **File > Print Setup**.
The menu is available in the modes:

- Design Layer
- Member Design
- Slab Design
- Earthquake

**D. Job Information** dialog

Used to provide general information and comments about the structure. When first opened, the dialog is populated with the data that is in the STAAD.Pro input file.

Some of the Job Information is printed in the header on every page of the reports. The rest may be printed in the special Job Information report item.

Opens when:

- **File > Job Information** is toggled on (a check is shown), or
- When **Des. Layer | Job Info** (on page 1202) page is selected.
Job
The job title (up to 100 characters) is printed in the report header.

Client
The client name (up to 100 characters) is printed in the report header.

Job No.
The job number (up to 100 characters) is printed in the report header.

Part
The part reference (up to 100 characters) is printed in the report header.

Ref
The reference (up to 100 characters) is printed in the report header.

Quality Assurance
Six edit boxes are available for recording information required by quality assurance procedures. There are spaces (10 characters) for the names or initials of the Engineer, the Checking Engineer and the Approving Engineer, together with dates.

Comment
Up to 1000 characters of comments can be typed into this edit box. The comments appear on the special Job Information report item.

D. (code) Report Setup dialog
Used to control the contents and look of your reports. The Report Setup command is sensitive to the current mode and to the current design code if in Design mode. That is, the menu item will display text

Opens when:

• File > (code) Report Setup is selected, or
the Report Setup tool is selected

Items tab

Groups Select the previously defined Design Group for which you want to generate a report.

Available list The Available list shows the tables and pictures that can be included in the report.

Tip: More than one item can be selected at once by holding down the CTRL key while selecting. A range of items can be selected by click and dragging up or down the list or clicking on the first item and clicking on the last whilst holding down the SHIFT key.

Selected list Results, tables, and pictures in this list will be included in the report, in the order in which they appear.

<table>
<thead>
<tr>

<tr>
<td>Page Outline</td>
<td>Select this option to add an outline to each page of the report.</td>
</tr>
<tr>
<td>Footer</td>
<td>Select this option to include a footer on the report. Note that the print run information, that is page numbers, time and date, is included on the footer.</td>
</tr>
<tr>
<td>Prefix</td>
<td>Sheet numbers are printed at the top right of each page. Edit the prefix for sheet numbers here. The prefix is printed one space in front of the sheet number.</td>
</tr>
<tr>
<td>No. Pages From</td>
<td>Give a number from which to start the sheet numbering.</td>
</tr>
<tr>
<td>Suffix</td>
<td>Edit the suffix for the sheet numbers at the top right of the page. Leave this text box empty if a suffix is not needed.</td>
</tr>
<tr>
<td>Reverse Page Order</td>
<td>Some printers do not turn over the pages that they have printed. This results in a printed report coming out back to front. If your printer does this, then select the Reverse Page Order option and QSE Space will print the last page first!</td>
</tr>
<tr>
<td>Grid</td>
<td>Select this option to draw the grid lines in the data tables of the report. Leaving the grid lines off increases printing speed on some printers.</td>
</tr>
<tr>
<td>Start each table on a new page</td>
<td>Select this option to start each new data table on a new report page. This option is useful for reports on very large structures, but it wastes paper on small structures where the tables are short.</td>
</tr>
<tr>
<td>Table Heading</td>
<td>Click on the Font... button to show the Font dialog for the table headings in the report. Choose a new font using the dialog and click the OK button to return to the Report Setup dialog.</td>
</tr>
<tr>
<td>Table Text</td>
<td>Click on the Font... button to show the Font dialog for the table text in the report. Choose a new font using the dialog and click the OK button to return to the Report Setup dialog.</td>
</tr>
</tbody>
</table>

Name and Logo tab

Configures the company name and logo area of the report page. This is situated in the box between the Bentley Systems logo (top left) and the Job No. box.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preview</td>
<td>Shows a preview of how the company name and logo appear. The company name is edited directly by typing in the preview.</td>
</tr>
<tr>
<td>File …</td>
<td>Click on the File button to insert a Windows Metafile graphic file into the company logo area.</td>
</tr>
<tr>
<td>Paste</td>
<td>Click to paste a bitmap or Windows Metafile image from the clipboard into the company logo area of the report header. If the button is inactive, the clipboard does not contain graphical data.</td>
</tr>
<tr>
<td>Position</td>
<td>Adjust the position of the graphic using these options. If the graphic is placed in the center, then the company name does not appear.</td>
</tr>
<tr>
<td>Font…</td>
<td>Opens a Font dialog, which is used to change the font and size of the text used for the company name. The text itself is edited directly in the Preview area.</td>
</tr>
<tr>
<td>Alignment</td>
<td>Adjust the alignment of the company name using these options. The company name is aligned within the space left after the company logo (if any) is drawn. Note that if the logo is placed in the center then the company name does not appear (although it is not deleted).</td>
</tr>
</tbody>
</table>
Load/Save tab

Used to save a report setup which can be recalled at a later date. The arrangement of Items, Members and Design Briefs with the sort options are saved.

When a picture is deleted, it is removed from all reports.

A Saved Report Setup can be deleted.

D. Print Setup dialog

Provides a list of installed printers, sets the default printer, and provides access to other printing options for the printer selected.

Opens when File > Print Setup… (on page 1107) is selected.

![Print Setup dialog]

**Default Printer**  Displays the name of the default printer and shows the printer’s connection.

**Printers**  Selects the printer to be used. Only printers that have been installed are listed here. For more information refer to the Windows documentation.

**Properties...**  Changes the printer settings from the printer selected in the Printers list. The options vary according to the printer driver installed.

**Network...**  Connects the computer to a printer across a network. For more information refer to the Windows documentation or press Help in the Network dialog.

**Orientation**  Select the orientation which you wished to be used for the printed output.

**OK**  Applies the Print Setup options and closes the dialog.

**Cancel**  Closes the dialog without making any changes.

D. Print dialog

Controls how the Concrete Design report is printed.

Opens when File > Print is selected.
**Printer**  Displays the name of the active printer and printer connection.

**Properties...**  Changes the printer settings from the printer selected in the Printers list. The options vary according to the printer driver installed.

**Print Range**  Select how much of the report is to be printed.

**Setup**  Displays the Print Setup dialog. This is equivalent to choosing the Printer Setup command from the File menu.

**OK**  Prints the report to the selected printer and closes the dialog.

**Cancel**  Closes the dialog without printing.

**D. Print Preview window**
Displays how the Concrete Design report appears when printed.

The arrangement and contents of a report are modified in the Report Setup dialog (on page 1110).

Open when **File > Print Preview** is selected.

When entering the print preview, Concrete Design repaginates the report and retrieves all the current data it needs, so the preview is the same as would be printed.

Design
D. Concrete Design

Print... Opens the Print dialog (on page 1114).

Next / Prev Page Moves the view forward and backward, respectively, through the report preview.

One / Two Page Toggles the display of the report preview between an single page and two page layout.

Zoom In / Out Magnifies or decreases the zoom level of the report preview.

Close Closes the Print Preview window and returns the to RC Designer window.

D. Edit menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undo [action]</td>
<td>Reverses the last change made to the active structure. The name of the command depends on the most recent action taken (e.g., Undo Delete). Note: Concrete Design cannot undo some actions. If the most recent action cannot be undone, then the name of the command reverts to Undo and it is disabled. Tip: To quickly reverse the most recent action on the active structure, click on the Undo button on the Standard toolbar.</td>
<td>Ctrl+Z</td>
</tr>
<tr>
<td>Cut</td>
<td>Removes the selected table data and puts it on to the Clipboard. Data cut to the clipboard replaces the previous contents of the clipboard. It remains on the clipboard until new data is cut or copied. This command is only available once a valid selection has been made in the active window. Tip: To quickly cut information to the clipboard, make a selection and then click the Cut button on the Standard toolbar.</td>
<td>Ctrl+X</td>
</tr>
</tbody>
</table>
### Menu item | What it does | Shortcut
---|---|---
**Copy** | Copies the selected table data and puts it on to the Clipboard. Data that is copied to the clipboard replaces the previous contents of the clipboard. It remains on the clipboard until new data is cut or copied. This command is only available once a valid selection has been made in the active window. **Tip:** To quickly copy information to the clipboard, make a selection and then click the Copy button on the Standard toolbar. | Ctrl+C

**Copy Picture** | Copies the picture in the active structure window to the clipboard. No selection is needed for this command to work. The picture replaces the previous contents of the clipboard and can be pasted into any windows application that supports graphics (e.g., Microsoft Office Word Excel). | 

**Paste** | Inserts a copy of the data on the clipboard into the active window. If the data on the clipboard is empty or is unsuitable for pasting into the active window, then the command is disabled. | Ctrl+V
### Menu item

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>Deletes the selection in the active window. A selection must be made for this command to be available. If the current window is a structure, a warning message is shown allowing the command to be canceled if required.</td>
<td>Delete</td>
</tr>
<tr>
<td>Tip:</td>
<td>If a mistake is made, use the Undo command on the Edit menu to reverse the delete. This must be done immediately after the mistake or the Undo may not be available.</td>
<td></td>
</tr>
<tr>
<td>Take Picture</td>
<td>Opens the Picture # dialog (on page 1120), which is used to copy the active structure window to an image for including in the report picture album. No selection is needed for this command to work. Photographs are stored for future use in a separate file in the same folder as the structure file with the same filename but with the file extension .REI Saved Picture.</td>
<td></td>
</tr>
<tr>
<td>Go To</td>
<td>Opens the GoTo Row dialog (on page 1120), which is used to scroll the active table window so that a given row is visible.</td>
<td>F5</td>
</tr>
</tbody>
</table>

The menu is available in the modes:

- Design Layer
- Member Design
- Slab Design
- Earthquake

D. Using table rows
When pasting into a table, any selected rows are overwritten. The paste command for a table keeps the data in the same order as it is on the clipboard.

If the data on the clipboard is longer than the selection in the active table, then the paste fills in any blank rows before appending the remaining data to the end of the table.

If the data on the clipboard is narrower than the active table, the data is pasted into the columns on the left of the table, leaving other columns unchanged or displaying default values.
If paste comes across an empty field in the clipboard data, it leaves any existing data alone, or enters a default value.

D. **Goto Row** dialog
Used to specify a row number for easy selection.

Opens when **Edit > Go To** is selected.

![Goto Row dialog](image)

**Row Number** Specify the row number (typically corresponds to beam, slab, element, etc. number) you want to select.

**OK** Selects the specified row number and closes the dialog.

**Cancel** Closes the dialog without selecting any other row.

D. **Picture #** dialog
Used to copy the active structure window to an image for including in the report picture album.

Opens when:
- **Edit > Take Picture** is selected, or
- The **Take Picture** tool is selected.

![Picture dialog](image)

**Id** Specify a title used to identify the photo in the Items list and Picture Album of a Report Setup (on page 1110).

**Caption** (Optional) Specify a caption to be used if the picture is a selected item in the Report Setup.

**OK** Accepts the changes made and closes the dialog.
**Cancel**  Closes the dialog without making any changes.

**D. View menu**

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Zoom</strong></td>
<td>Opens a Zoom Window onto the active structure window.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When the Zoom command is chosen, the cursor changes to a cross (+).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Define a zoom area on the structure window. Press down the left mouse button on one corner of this area, hold down the button and move the mouse (drag) to open up the area. The zoom area is outlined with a dotted box as it is dragged. Release the mouse button when the area is the desired size.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>A &lt;Zoom&gt; window is now opened showing the zoom area enlarged. If the Highlight Zoom Area option is checked in the options dialog, a box appears on the structure window, locating the extents of the zoom window.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Only one zoom window per structure window can be open. A zoom window cannot be opened from another zoom window. However, the scale of zoomed area can be increased or decreased by clicking on the ‘+’ or ‘-’ buttons on the bottom right of the zoom window.</td>
<td></td>
</tr>
<tr>

</table>

The menu is available in the modes:

- Design Layer
- Member Design
- Slab Design
- Earthquake

D. **Tables** dialog
Used to toggle the display of tables in the RC Designer interface.

Opens when:

- **View > Tables** (on page 1121) is selected, or when
• **Other Tables** is selected from a table right-click menu.

![Table Selection Dialog]

**Tables list** Select the tables you want to display by clicking the check box associated with each.

- In the case of the Load Summary table, the Tables dialog affects only the load summary associated with the active structure window.

**List** Select to display Design Input and/or Design Results by clicking the check box associated with each. These options can be used to limit the list of tables to help find items more easily.

**OK** Closes the dialog and the selected tables are displayed.

**Cancel** Closes the dialog without toggling the display of any tables.

**D. Diagrams (Structure) dialog**

Used to control the display of the structure, loads, and other graphical items for viewing and reports.

Opens when:

- **View > Structure Diagrams** (on page 1121) is selected, or

- The **Structure Diagrams** tool is selected.

General tab
**Depth Sorting**

Both these options should be considered if the Fill Plate option is selected below.

- Sort Geometry option
- Sort Nodes option

**Plates and Slabs**

These options determine the view characteristics of a model with finite elements

- Fill Plates option
- Slab Edges option
- Hide Slab Interior Edges option

**Margin Around Structure**

Sets the percentage of the window to allow around the structure to allow for drawing force diagrams.

Results tab

Sets the results to be displayed and their colors.
Load Case A pull-down list of all defined load cases and combinations.

Forces Check boxes to toggle the display of the particular force on the structure. The color on the adjacent button shows the color of that diagram. Click on the button to select an alternative color.

Increments This sets the number of intermediate results that are shown for each element.

Scales tab
Sets the scales that loads and results are to be displayed to. Note that units for each item is set in the Options dialog. If the range does not provide a suitable scale, try alternative units.

- **Load Scale**: Range 0.001-999999
- **Bending Scale**: Range 0.001-999999
- **Shear Scale**: Range 0.001-999999
- **Axial Scale**: Range 0.001-999999
- **Torsion Scale**: Range 0.001-999999
- **Disp. Scale**: Range 0.001-999999

**Labels tab**

Displays the Labels page of the Diagrams dialog for the active structure window.
The dialog contains check boxes for configuring which labels appear on the structure diagram in the active window.

The user must choose between display of section property References or the names of the Sections.

**Node Labels**
- Nodes Numbers
- Node Points
- Supports

**Element Labels**
- Element Numbers
- Orientation Labels
- Element Length

**Property Labels**
- None (select option)
- Reference (select option)
- Section (select option)

**Member Labels**
- Member Numbers
- Group References

**General**
- Axes Diagram

Force Limits tab
Used to color the stick line model of the structure to indicate which elements have end forces or stresses that fall outside a specified range.

**Label Case**  A pull-down list of all loadcases, combinations and envelopes. Note that loadcase chosen in this pull-down updates the similar pull-down on the Results tab and vice versa.

**View Limits**  Choose the range. Whether the maximum limit, minimum limit or both should remain within range.

**Colour within limit**  Click on the colored box to change the pass color and set the thickness of line in pixels between 1 and 10 (structure elements are always drawn 1 pixel wide).

**Colour outside limit**  Click on the colored box to change the fail color and set the thickness of line in pixels between 1 and 10 (structure elements are always drawn 1 pixel wide).

**OK**  Accepts the changes made and closes the dialog.

**Cancel**  Closes the dialog without making any changes.

**Apply**  Applies any changes made in the dialog. Only active if changes have been made.

**Help**  Opens the STAAD.Pro help window.

**D. Colour Manager** dialog
Used to select graphics colors for various plot elements.

Opens when **View > Colours** (on page 1121) is selected.
**Structure Colours**
Sets the colors used in various highlights.

**Analysis Results**
Sets the colors for the Forces (see also Structure Diagrams) and element Limits.

**Design Results**
Sets the colors for the Pass/Fail ratios and member efficiencies.

**Current Structure Colour Scheme**
Sets the colors for the drawing the wire frame of the structure. The chosen scheme is displayed in the status bar (on page 1217).

**OK**
Accepts the changes made and closes the dialog.

**Cancel**
Closes the dialog without making any changes.

**D. Orientation** dialog
Used to adjust the orientation and projection of the picture of the structure in the active structure window.

Opens when **View > Orientation** (on page 1121) is selected.
Dialog controls

**View**
Choose between Isometric and Perspective drawing.

**Default Orientation To**
Click on one of these buttons to set the Elevation, Distance and Rotation to default values.

**Distance to Structure**
The distance from the viewpoint to the origin of the structure.

**Elevation Angle**
The height above ground level (global $Z = 0$) for Perspective drawing, or the projection angle used for Isometric drawing.

**Rotation Angle**
The rotation of the structure about the global $Z$ axis.

**Apply Immediately**
Check this box to see the picture in the active structure window redraw as soon as changes are made in the dialog.

**Apply**
Click to apply the changes in the dialog to the drawing in the active structure window.
This button is not needed if the Apply Immediately box is checked.

**Restore**
Restores the values in the dialog to those that were current when it was opened. Be careful because any changes made are lost.

**Close**
Closes the dialog and applies any changes made to the picture in the active structure window.
To cancel changes, click on the Restore button before clicking on Close.

D. **Open View** dialog
Used to open a saved view of the structure.

Opens when **View > Open View** (on page 1121) is selected.
Dialog controls

**Views**  Choose the view to be opened from the list of stored views.

**Options**  A new window in which to open the view can be created, or the view can be opened in the currently active structure window.

**OK**  Opens the selected view in the selected window and closes the dialog box.

**Cancel**  Closes the dialog without opening a view.

**Related Links**
- [D. Reopening a saved view](on page 1016)

D. **Add to View** dialog
Used to add elements which are selected in the active window to another view window which has already been created.

Opens when View > View Management > Add to View... (on page 1121) is selected.
### Design

**D. Concrete Design**

<table>
<thead>
<tr>
<th>Structure</th>
<th>The file name of the active structure is displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Views</td>
<td>Select the view name to which the selected elements are to be added.</td>
</tr>
<tr>
<td>OK</td>
<td>Accepts the changes made and closes the dialog.</td>
</tr>
<tr>
<td>Cancel</td>
<td>Closes the dialog without making any changes.</td>
</tr>
</tbody>
</table>

**D. Save View As dialog**

Used to save the view in the active window in the data file for the active structure. The view window can then be closed without losing the view.

Opens when **View > View Management > Save View** (on page 1121) is selected.

![Save View As dialog](image)

**Name**

Specify a name for the new view. A list of existing view names is shown below. Selecting one of these will copy the name into and, once OK is clicked, you will be prompted to over write the existing view.

If the content, diagrams or annotation of a saved view are changed, the view is marked as changed by having an asterisk * added to its name. A view with a * appended to its name must be saved in order to retain the changes.

**Tip:** Because Concrete Design uses an asterisk at the end of a view name to indicate that it has changed since it was last saved, it is not recommended to use an asterisk in a view name.

**OK**

Save the new view and closes the dialog.

**Cancel**

Closes the dialog without saving a new view.

**D. Rename View dialog**

Used to rename saved view in the active window.

Opens when **View > View Management > Rename View** (on page 1121) is selected.
**Old Name**  Displays the existing name of the view selected for renaming.

**New Name**  Specify a new name to use for the selected view.

**OK**  Updates the view name and closes the dialog.

**Cancel**  Closes the dialog without changing the view name.

**D. Toolbar Setup** dialog

Used to open toolboxes.

Opens when:

- **View > Toolbars** (on page 1121) is selected, or
- **Toolbars** is selected from the toolbar right-click pop-up menu.

---

**Dialog controls**

**Toolbars**  Allows you to see a list of all available toolbars in Concrete Design. The toolboxes with a check mark next to them are already open. To open a toolbox, you must place a check mark in its check box by clicking it. Single-clicking a check box or a toolbox's name places a check mark in the check box, which will open the toolbox.

**Large Buttons**  If checked, displays the tool icons as larger than their normal size. The default is unchecked. This feature is useful if Concrete Design is run on a very high resolution screen or if you have difficulty seeing the normal size buttons.

**Note:** Although increasing the button size may help you, it also reduces the space in which Concrete Design can draw the structure.
Show Tool Tips
If checked (the default), the name of the tool appears as you pass the pointer over the tool's icon. This option is helpful for learning names and functions the tools in Concrete Design.

**Tip:** When the mouse cursor is placed over a tool, the Status Bar provides additional context to the tool's function.

OK
Closes the dialog and opens all toolboxes with a check mark next to them in the list box. Tool size and tool tip display will also be applied at this time.

Cancel
Closes the dialog without opening the toolboxes that you just checked or applying other options.

**D. Options** dialog
Used to configure many of the graphical features of Concrete Design.

Opens when **View > Options** (on page 1121) is selected.

**View Highlight** tab
Contains the options to configure the appearance of the highlights between structure windows in Concrete Design.

View Highlight
Changes the view highlight colors of the elements in the active view or in the whole structure window, if it is open. This helps locate elements in the view.

Zoom Area
The zoom area of a Zoom window is highlighted on the original window. It helps locate the zoomed in area on the original.

Width
Edit the width of the highlights using the edit box.
Tables tab

Contains a button to configure the font used in the tables in Concrete Design. Click on the Font button to change the font. A sample of the font chosen is displayed.

Font... Click on the Font button to change the font. A sample of the font chosen is displayed.

Note: This font is only used when Page Control is turned off. This is because with Page Control turned on and a very large font would cause problems on pages that have wide tables and picture views.

Node Labels tab

Contains the options for configuring how the node labels on the picture of the structure appear, if used.

To turn Node Labels on, use the Labels command on the View menu.

Figure 137: Nomenclature used in the placement of node labels
**Style**
Choose the style of the node labels.

**Horizontal Alignment**
Choose an option for the horizontal alignment of the node label with respect to the start point for the text.

**Vertical Alignment**
Choose an option for the vertical alignment of the node label with respect to the start point for the text.

**Pixels Right & Above**
Enter the distance in pixels from the node to the start point for the text.

**Font**
Click on the Font button to change the font used for the label. The font colour can also be changed here.

**Opaque**
Select this option to make the label opaque. This obscures any structure or diagram behind the label, ensuring that it can be read.

**Sample**
A graphical preview of how the current settings will display node labels.

**Element Labels tab**
Contains the options for configuring how the element labels on the picture of the structure appear, if used.

**Note:** To turn Node Labels on, use the Labels command on the View menu.

**Figure 138: Nomenclature used in the placement of element labels**
Elements Style & Properties Style
Choose the style of the labels. Configure the style used for the property independently of the style used for the element reference. The property reference is appended to the element reference separated by a colon. e.g. E34 : P2

Horizontal Alignment
Choose an option for the horizontal alignment of the label with respect to the text start position.

Vertical Alignment
Choose an option for the vertical alignment of the label with respect to the text start position.

Pixels Right & Above
The text start point is positioned with respect to the center point of the element. Enter the distance in pixels from the element center to the start point for the text.

Font
Click on the Font button to change the font used for the label. The font colour can also be changed from here.

Opaque
Check this box to make the label opaque. This obscures any structure or diagram behind the label, ensuring that it can be read.

Angle Text
Check this box to angle the label along the line of the element. If this box is unchecked, the label is drawn horizontally.

Sample
A graphical preview of how the current settings will display element labels.

Plate Labels tab
Structure Units tab

Section Units tab
Force Units tab

**OK** Closes the dialog and applies changes to the graphical display.

**Cancel** Closes the dialog without applying any changes.

**Apply** Applies changes to the graphical display.
Help  Opens the STAAD.Pro help window.

D. Diagrams (slab) dialog
Used to control the graphical display of slab related diagrams and plots.
Opens when View > Diagram (on page 1121) is selected (in the Concrete Slab mode)

General tab
Used to control the view of items pertaining to the slab geometry and constituent elements.

Analysis Contour tab
Used to control the display of the analysis plots.
Diagram
Select which of the effect plots can be generated.

Loading
Sets the active loading envelope or load case.

Spacing of Sample points
Sets the level of plot refinement.

Style
Switches plots to line contour or filled contour.
Principal stress directions will also be shown if the box is selected.

Direction \ Result Set
Sets plot directions with respect to one of the available options.

Design Contour tab
Diagram
Used to select plot content: design moments, required reinforcements or spacing of bars.

Face / Direction / Style
Top or bottom reinforcement together with directions and contour style can also be selected with the available options.

D. Select menu
This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Elements Cursor</td>
<td>Choosing one of the cursor commands changes the cursor shape and its selection function when it is over a structure window. The elements cursor allows individual analytical elements to be selected and joined into design members.</td>
</tr>
<tr>
<td>Members Cursor</td>
<td>Used for limiting selections to members.</td>
</tr>
<tr>
<td>Plates Cursor</td>
<td>Used for limiting selections to plates.</td>
</tr>
<tr>
<td>Slabs Cursor</td>
<td>Used for limiting selections to slabs.</td>
</tr>
<tr>
<td>Select All</td>
<td>The action of the Select All command depends on the current selection mode and cursor.</td>
</tr>
<tr>
<td></td>
<td>• If the Select Elements cursor is current then all the elements in the active structure window are selected.</td>
</tr>
<tr>
<td></td>
<td>• If the Select Nodes cursor is current then all the nodes in the active structure window are selected.</td>
</tr>
<tr>
<td></td>
<td>• If the Select Element Ends cursor is current then all the element ends in the active structure window are selected. Note that this may look similar to all the elements being selected, but it is not the same.</td>
</tr>
<tr>
<td>By Members</td>
<td>Opens the Select Members dialog (on page 1147), which is used to select members in the active structure window by their member numbers.</td>
</tr>
<tr>
<td>Menu item</td>
<td>What it does</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>By Section Property</td>
<td>Selects elements in the active structure window according to their section property. Displays the Select by Property dialog which contains a list of the section properties defined in the active structure and the option of 'No Property' (a useful check to see that all elements do have a property prior to analysis). Click on properties in the list to select them. Extend the selection by holding down the CTRL key and clicking on further properties. Click OK to update the selection in the active structure window. To quickly show the Select by Property dialog, click the Select by Property button on one of the toolbars.</td>
</tr>
<tr>
<td>By Design Group</td>
<td>Opens the Select Members by Design Group dialog (on page 1148), which is used to select members in the active view window by entire design group. <strong>Note:</strong> Before selecting by Design Group, at least one design group must be defined.</td>
</tr>
<tr>
<td>New Design Group</td>
<td>Opens the New Design Group dialog (on page 1149), which is used to associate a design brief for a Design Group from the currently selected member(s). A Design Group is the selection of members that are to be designed with one of the Concrete Design modules. <strong>Note:</strong> Before defining a new Design Group, one or more members must be selected in the active structure window.</td>
</tr>
</tbody>
</table>

The menu is available in the modes:

- Design Layer
- Member Design
- Earthquake

D. Select Members dialog
Used to select members in the active structure window by their member numbers.

Opens when **Select > By Member** (on page 1146) is selected.
Displays the Select Members dialog which contains a single list box with all the member numbers. The selection in this list reflects any selection already made on the active structure window.

**Tip:** Extend the selection in the list by holding down the **CTRL** key while selecting new members. To remove a selection from the list, hold down the **CTRL** key and click on the item.

Click **OK** to transfer the selection to the active structure window.

**D. Select By Property** dialog

Used to select elements in the active structure window according to their section property.

Opens when **Select > By Section Property…** (on page 1146) is selected.

**List**

Displays the Select by Property dialog which contains a list of the section properties defined in the active structure and the option of 'No Property' (a useful check to see that all elements do have a property prior to analysis). Click on properties in the list to select them.

**Tip:** Extend the selection by holding down the **CTRL** key and clicking on further properties.

**OK**

Updates the selection in the active structure window.

**Cancel**

Closes the dialog without performing any selections.

**D. Select Members by Design Group** dialog

Used to select members in the active view window by entire design group.

Opens when:

- **Select > By Design Group…** (on page 1146) is selected, or
- **Groups > Select by Design Group…** (on page 1159) is selected.
Displays the Select Design Groups dialog which contains a list of the groups defined in the active structure. Click on groups in the list to select them.

**Note:** Extend the selection by pressing the `<CTRL>` key and clicking on additional groups.

**OK**
Updates the selection in the active structure window and close the dialog.

**Cancel**
Closes the dialog without selecting any members by design group.

**Rename...**
Opens the Rename Design Group dialog (on page 1149).

Rename... is enabled when a single design group is selected in the list.

**Delete**
Click to delete the selected Design Group(s). Only the design group is will be removed; all physical members will remain in the design model.

**Caution:** This action cannot be undone. No confirmation dialog will be presented before deleting groups.

Delete is enabled when one or more design group is selected in the list.

**D. Rename Design Group** dialog
Used to rename an existing design group.

Opens when the Rename... button is clicked in the Select Members by Design Group dialog (on page 1148).

**Old Name**
Displays the existing name of the design group selected for renaming.

**New Name**
Specify a new name to use for the selected design group.

**OK**
Updates the Design Group name and closes the dialog.

**Cancel**
Closes the dialog without changing the group name.

**D. New Design Group** dialog
Used to associate a design brief for a Design Group from the currently selected member(s).

Opens when:

- The Edit Design Group button is clicked on the Design Groups Table, or
- Select > New Design Group (on page 1146) is selected, or
- Groups > New Design Group (on page 1159) is selected, or
- The New Design Group tool is selected.

![New Design Group dialog]

G# Enter a name to identify the design group. The default name is incremented automatically.

Design Brief Select a previously defined group design brief.

OK Creates the Design Group with the specified options and closes the dialog.

Cancel Closes the dialog without creating a Design Group.

### D. Members menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Members Table</td>
<td>Displays the [D. Members table](on page 1151) for the active structure. This table is un-editable, but clicking on a member reference number will highlight that member on the diagram.</td>
</tr>
</tbody>
</table>
### Menu item | What it does
---|---
Form Members | Forms a physical member from a selection of one or more connected elements.
**Note:** One or more analytical elements must be selected for this command to be available.
**Note:** If the selection of elements is not connected then the form member command uses the first connected part of the selection only. A warning regarding this appears.
**Tip:** To view the members in the structure, use the Member Labels option in the Labels dialog which is available from the Labels command on the View menu.
See [D. Design of Members and Slabs](on page 1008) for how to use this tool.
AutoForm Members | Forms a number of Members from a selected range of elements. Each member will obey the general rules for generating a member specified (those listed for *Form Member*), but uses the following rules in addition.
- Vertical elements are converted into columns first.
- Where four elements cross and share a single node, if the elements can form two members, the deeper section will form a continuous member, but the other elements will form parts of two separate members.
Unform Member(s) | The menu is available in the modes:
- Design Layer

D. **Members** table
List all members, including their analytical parts. This table is for information only and is not editable.
Opens when:
- The [Des. Layer | Members page](on page 1202) is selected, or
- When [Members > Members Table](on page 1150) is selected, or
- The [Members Table](tool) tool is selected.
Tip: Selecting a Physical Member (or constituent analytical member) reference number will highlight that member in the View window.

Note: Analytical members are read from the STAAD.Pro input file. See D. Rules for Forming Members (on page 1009) for forming Physical Members.

Table Columns
- **Mem**: The reference number of the member.
- **Emt**: The elements that form the particular member.
- **A B**: The nodes that define the start and end of the element.
- **Prop A, Prop B**: The reference of the section properties at the start and end of the element.
- **Length**: The length of the element (in the chosen units).
- **O. length**: The overall length of the member, reduced by any cutbacks if applied (in the chosen units).

Menu Item | Description | Shortcut
--- | --- | ---
Cut | Copy the selected contents to the clipboard and delete from the table. | <Ctrl+X>
Copy | Copy the selected contents to the clipboard. | <Ctrl+C>
Paste | Paste the clipboard contents to the table. | <Ctrl+V>
Go To... | Opens the dialog box (on page 1120), which is used to specify a row number for easy selection. | <F5>
Other Tables…
Opens the dialog box (on page 1126), which is used to toggle the display of tables in the RC Designer interface.

### D. Slabs menu
This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slabs Table</td>
<td>Opens the [D. Slabs table](on page 1153) for the active structure.</td>
</tr>
<tr>
<td>Form Slab</td>
<td>Forms a structural slab from a selection of one or more connected F.E. elements. Elements must be selected for this command to be available. If the selection of elements is not connected then the form Slab command uses the first connected part of the selection only. A warning regarding this appears. To view the slabs in the structure, use the Slabs Number option in the Labels dialog which is available from the Labels command on the View menu. See [D. Design of Members and Slabs](on page 1008) for how to use this tool.</td>
</tr>
<tr>
<td>AutoForm Slab</td>
<td><strong>Attention:</strong> This feature is currently inactive.</td>
</tr>
<tr>
<td>Uniform Slab</td>
<td>Deletes the selected the slab(s) and free the constituent elements.</td>
</tr>
<tr>
<td>Add to Slab</td>
<td><strong>Attention:</strong> This feature is currently inactive.</td>
</tr>
<tr>
<td>Remove from Slab</td>
<td><strong>Attention:</strong> This feature is currently inactive.</td>
</tr>
</tbody>
</table>

The menu is available in the modes:
- Design Layer
- D. Slabs table
Used to display information for the slabs in the active design file.

**Note:** This table is not editable.
Tip: Selecting a Slab reference number will highlight that slab in the View window.

Table Columns

<table>
<thead>
<tr>
<th>Slab</th>
<th>The reference number of the Slab.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thickness</td>
<td>The slab thickness in cm. If thickness varies, 'Variable' is displayed in this column</td>
</tr>
<tr>
<td>Net Area</td>
<td>The net area of the Slab, excludes area of holes</td>
</tr>
<tr>
<td>Gross Area</td>
<td>The gross area of the Slab</td>
</tr>
<tr>
<td>Holes</td>
<td>Number of holes identified in the Slab</td>
</tr>
<tr>
<td>Plates</td>
<td>Number of F.E. forming the Slab</td>
</tr>
</tbody>
</table>

D. Brief menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design Brief</td>
<td>Opens the Edit Design brief dialog for the currently selected design brief. A Design Brief is a set of design parameters, which allows the Concrete Design checks to be done. Each Design Brief is setup for a particular Design Code. Briefs are independent of Member Design Groups so that the same brief can be re-used for several design groups. For example, you may have several groups of beams but only one brief for beams. Alternatively, you may tailor each brief to each member group. See D. Design Briefs (on page 1010) for a list of available codes.</td>
</tr>
<tr>
<td>Design Brief Table</td>
<td>Opens the D. Design Briefs table (on page 1155), which lists the design briefs already defined and the codes of practice used for each brief. See D. Design Briefs (on page 1010) for additional information</td>
</tr>
</tbody>
</table>
The menu is available in the modes:

- Design Layer
- Member Design
- Slab Design
- Earthquake

D. Creating a new design brief

1. Click the first empty Brief cell in the Design Brief table.
2. Type a name for the Brief.
3. Press `<Tab>`.
4. Select a Design code to use for this brief.
5. (Optional) Click the Edit Brief button to specify brief details.

D. Deleting a design brief

1. Select the brief's entry in the Design Brief table.
2. Either:
   - Select Edit > Delete.
   - or
   - Press <Delete>.

D. Editing an existing brief

1. Either:
   - Double click the brief's entry in the Design Brief table.
   - or
   - Select the entry with the cursor and then press the Edit Brief button.
   The `<code>` Design Brief dialog (on page 1218) opens.

D. Changing the design code for a brief

1. Select the code cell for the brief you want to change.
   A drop-down list of all beam and column codes available appears in the cell.
2. Select a new code from the list.

D. Design Briefs table
Lists the design briefs already defined and the codes of practice used for each brief.

Opens when:

- Brief > Design Brief Table is selected, or
- The Des. Layer | Groups/Briefs (on page 1202) page is selected.
Design Brief table

Lists all design briefs in the current model.

- **B#** - Number assigned to the design brief (not editable).
- **Brief** - Title for the design brief. Click in the cell to edit the text.
- **Code** - Design code and type associated with the design brief. Click in the cell to select a different code and type pair.

**Note:** If the brief already has been assigned to a Design Group, then any design data for that group will be removed. A warning dialog will appear asking to confirm a change in this case.

**New Brief**

Opens the **New Design Brief** dialog (on page 1156).

**Edit Brief**

Opens the Edit Design Brief dialog for the selected table entry. Refer to the various codes for details on the design parameters for each.

<table>
<thead>
<tr>
<th>Menu Item</th>
<th>Description</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cut</td>
<td>Copy the selected contents to the clipboard and delete from the table.</td>
<td>&lt;Ctrl+X&gt;</td>
</tr>
<tr>
<td>Copy</td>
<td>Copy the selected contents to the clipboard.</td>
<td>&lt;Ctrl+C&gt;</td>
</tr>
<tr>
<td>Paste</td>
<td>Paste the clipboard contents to the table.</td>
<td>&lt;Ctrl+V&gt;</td>
</tr>
<tr>
<td>Go To...</td>
<td>Opens the dialog box (on page 1120), which is used to specify a row number for easy selection.</td>
<td>&lt;F5&gt;</td>
</tr>
<tr>
<td>Other Tables...</td>
<td>Opens the dialog box (on page 1126), which is used to toggle the display of tables in the RC Designer interface.</td>
<td></td>
</tr>
</tbody>
</table>

**D. New Design Brief** dialog

Used to assign a title, design code, and design type to a new brief.

Opens when the New Design Brief button is clicked on the **Design Briefs table** (on page 1155).
B# Specify a title to describe the new design brief.

Design Code Select the governing building code for the design of the members in this brief.

Design Type Select the structural elements used in the group to which this design brief will be assigned: Beam, Column, or Slab.

**Note:** Not all element types are supported for all codes.

OK Creates the new design brief and closes the dialog.

Cancel Closes the dialog without creating a new brief.

D. **Bending Dimensions** dialog

Used to specify custom bending dimension radii for use with a user-specified shear steel yield strength.

Opens when **Bending Dimensions**... is clicked on the Shear Reinforcement tab of a beam design brief dialog.
### Minimum Bending Radius

Enter a minimum bar radius to be used for the corresponding bar size (in current length units).

### Anchorage provided by a bend as a multiple of bar size

(Shear Reinforcement only) Specify a numeric value which represents the anchorage length provided by a bar bend (hook). This value is provided in terms of multiples of a bar diameter, and therefore is unitless.

### OK

Accept the specified values and closes the dialog.
## Cancel

Closes the dialog without updating any value.

## D. Group menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select By Design Group</td>
<td>Opens the Select Members by Design Group dialog (on page 1148), which is used to select members by entire design group. Note: Before selecting by Design Group, member groups must be defined for the structure.</td>
</tr>
<tr>
<td>Group Members List Table</td>
<td>Opens the Group Member List table (on page 1160), which displays a list of the members in the current design group with their Analysis and Design sections.</td>
</tr>
<tr>
<td>New Design Group</td>
<td>Opens the New Design Group dialog (on page 1149), which is used to create a new design group from the currently selected member(s). A Design Group is the selection of members that are to be designed with one of the Concrete Design modules. Note: Before defining a new Design Group, one or more members must be selected in the active structure window.</td>
</tr>
<tr>
<td>Design Group Table</td>
<td>Opens the Design Groups Table (on page 1160), which contains the elements and design briefs associations used for designing elements in groups. This table is opened automatically when the Des.Groups option in Page Control Mode is selected. Tip: To open this table when not running in Page Control Mode, select the table from the Tables dialog (on page 1126).</td>
</tr>
<tr>
<td>Member Summary</td>
<td></td>
</tr>
<tr>
<td>Export Group for Detailing</td>
<td>Opens the Export Design Group to Bentley Rebar dialog (on page 1161), which is used to select members for exporting to external detailing programs, such as Bentley Rebar.</td>
</tr>
</tbody>
</table>

The menu is available in the modes:

- Design Layer
Member Design

D. Group Member List table
Displays the members which make up a Design Group, along with the sections used for analysis and design.
Opens when:

- **Groups > Group Member List Table** is selected, or
- When Edit Design Group button is clicked on the **D. Design Groups table** (on page 1160).

![Group Member List Table](image)

Analysis and Design section displayed are those used in the last analysis or design performed, respectively. The design section will display the last analysis section used if no design has been performed. These cells are for information purposes only and cannot be edited.

**Note:** To add a member to the design group, type the member number, omitting the “M”, in the first column of the table.

See **D. Design Groups** (on page 1012) for information on adding or removing members from a design group.

<table>
<thead>
<tr>
<th>Menu Item</th>
<th>Description</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cut</td>
<td>Copy the selected contents to the clipboard and delete from the table.</td>
<td>&lt;Ctrl+X&gt;</td>
</tr>
<tr>
<td>Copy</td>
<td>Copy the selected contents to the clipboard.</td>
<td>&lt;Ctrl+C&gt;</td>
</tr>
<tr>
<td>Paste</td>
<td>Paste the clipboard contents to the table.</td>
<td>&lt;Ctrl+V&gt;</td>
</tr>
<tr>
<td>Go To...</td>
<td>Opens the dialog box (on page 1120), which is used to specify a row number for easy selection.</td>
<td>&lt;F5&gt;</td>
</tr>
<tr>
<td>Other Tables...</td>
<td>Opens the dialog box (on page 1126), which is used to toggle the display of tables in the RC Designer interface.</td>
<td></td>
</tr>
</tbody>
</table>

D. Design Groups table
Contains the elements and design briefs associations used for designing elements in groups. The content of the table is grouped into two tabs: Members and Slabs.
Opens when:

- The Des. Layer | Groups/Briefs mode is selected, or
- when **Groups > Design Group Table** (on page 1159) is selected, or
The Design Groups table tool is selected.

![Image of Design Groups table with Members tab selected]

**Figure 139: Design Groups table with the Members tab selected**

**Members tab**

- **Member design group table**
  Each row of the table represents a separate design group, with the group number, Design Group title, and associated Design Brief.

- **New Design Group**
  Click to open the New Design Group dialog (on page 1149), which is used to create a new design group from selected member(s) and associate it with a design brief.

- **Edit Design Group**
  Click to edit the members included in a design group.

**Slabs tab**

- **Design slab table**
  Each row of the table represents a separate design slab, with the slab number, Design Slab title, and associated Design Brief.

- **New Design Slab**
  Click to open the New Design Slab dialog (on page 1162), which is used to create a new design group from selected slab and associate it with a design brief.

- **Edit Design Slab**
  Click to open the Edit Design Slab dialog, which is used to edit the slab or associated design brief included in a design slab.

**D. Export Group to Bentley Rebar**

Used to select members for exporting to external detailing programs, such as Bentley Rebar. The design data can be saved in either a STAAD Markup Language File (file extension .stml) or a Bentley Rebar Link Binary File (file extension .brl).

Opens when Groups > Export Group for Detailing (on page 1159) is selected.

**Note:** Refer to AD.2006-1004.4.1 in the What's New section of the STAAD.Pro help for additional information on using this feature with Bentley Rebar.
Available list  Contains all members within the selected design group.

Selected list  Contains all members which will be included in the export. By default, all members in the group are included.

Cancel  Closes the dialog without exporting any data.

Export  Closes the dialog and opens a Save As dialog for selecting a location and filename (by default, the convention of [STAAD Input File]_[Group Title] is used for the filename). The file filter is set to either a STAAD Markup Language file or a Bentley Rebar Link binary file, depending on the program to which you want to export the data.

Help  Opens the STAAD.Pro help window.

Note: MicroStation and Bentley Rebar are separate products from STAAD.Pro and are independently licensed. If you do not have copies of these products, please contact your STAAD.Pro provider.

D. New Design Slab dialog
Used to associate a design brief and slab for a Design Slab.

Opens when the New Design Slab button is clicked in the Design Groups Table (on page 1160).
**SD#**
Enter a name to identify the design slab. The default name is incremented automatically.

**Design Brief**
Select a previously defined slab design brief.

**For Slab**
Select a physical slab number.

**OK**
Creates the Design Slab with the specified options and closes the dialog.

**Cancel**
Closes the dialog without creating a Design Slab.

### D. Result Line menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create</td>
<td>Used to define a line through the slab for which a set of force and/or displacement results will be established.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the result line and clears associated result plots.</td>
</tr>
<tr>
<td>Result Line Graph</td>
<td>Opens the <a href="#">Result Line Graph and table</a> (on page 1213), which displays a cross section result of the results displayed on the slab and is used to examine the results.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: If the graph is already open, then the focus is switched to this window.</td>
</tr>
<tr>
<td></td>
<td>The Result Line Graph displays a cross section result of the results displayed on the Slab. This can be changed by selecting the required result from the toolbar drop list or by selecting View &gt; Diagram.</td>
</tr>
<tr>
<td>Constrain to Slab X</td>
<td>If this option is set, when <a href="#">creating a Result Line</a> (on page 1164), the line is fixed to lie parallel to the Slab X axes.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: This option can be turned off by selecting Result Line &gt; Unconstrained.</td>
</tr>
</tbody>
</table>
The menu is available in the modes:

- Slab Design

D. Drawing a result line

1. Either:
   
   Select Result Line > Create.
   or
   
   Select the Result Line tool

   The mouse pointer changes to a Result Line cursor.

   **Tip:** When the command is active, a tick is displayed against the menu item and the toolbar button is shown as depressed.

2. Click once to define a start point for the Results Line.
   
   A line is rubber-banded from this point to the mouse pointer.

   **Tip:** Select Result Line > Constrain to Slab X to limit the result line to parallel to the slab local x-axis.

3. Click a second time to define the end point.

   **Note:** While the line can be created by clicking on any two points within the Slab Diagram window, the line will be extended such that it will cross the entire slab and cross any openings if present. See D. Slab Alignment dialog (on page 1165) for more details.

4. Repeat steps 2 through 3 to redraw result lines.

5. Press <Esc> to stop drawing Result Lines (or simply click a different page).

**D. Slab menu**

This menu contains the following commands:
Slab Axes

What it does

Opens the Slab Alignment dialog (on page 1165), which is used to define the X axis of the slab.

Set Axes from Line

What it does

If a result line exists, with this command you can set the slab X axes to coincide with it.

Note: After the slab axes is set, the option Constrain to Slab X is set.

The menu is available in the modes:

- Slab Design

D. Slab Alignment dialog

Used to define the X axis of the slab.

Opens when:

- Slab > Slab Axes (on page 1164) is selected, or
- The Slab Axes tool is selected.

The Slab Alignment dialog can be used to define the X axis of the slab. It contains the following options:

- **Perimeter Node**
  - Used to define a line from one perimeter node to another representing the X axes of the slab. The drop down lists contains all the perimeter nodes.

- **Component Plate**
  - Used to realign the slab axis with the local axis of the selected element from the list.

- **Additional Rotation**
  - This value specifies the further rotation of the slab axis by the specified angle in degrees.

- **OK**
  - Accepts the slab alignment parameters and closes the dialog.

- **Cancel**
  - Closes the dialog without saving any settings.

D. Regions menu

This menu contains the following commands:
### Menu item | What it does
--- | ---
**Draw Boundaries** | Used to draw a line with in a slab, which represents a boundary line for Regions within a slab. It can be drawn from one boundary node to another.

**Select Region Boundaries** | Used to select Region boundaries for deletion. When a Region's boundary is deleted, Concrete Design automatically combines the merged Regions.

**Reset Regions** | This command will erase all Regions boundaries, defaulting back to the original layout that has the slab being a single region.

The menu is available in the modes:

- Slab Design

- [D. Changing the orientation of a region](#) (on page 1167)

**D. Drawing a new region boundary**

1. Select the **Concrete Slab | Regions** page.
2. Either:
Select **Regions > Draw Boundaries**.

or

Select the **Add Boundary** tool.

The cursor changes to the Add Boundary pointer in the View window.

3. Click the first node to define the boundary between two regions.
   A dashed line is “rubber banded” to this node from the mouse pointer.
4. Click the second node used to define the region boundary.
   A solid line is added to show the boundary between the two newly created regions. Labels and local axis are also added to each region, if these are set in the **Diagram (slab) dialog General tab** (on page 1144).

**Related Links**

- **D. Regions menu** (on page 1165)

D. Deleting a region boundary

1. Either:
   Select **Regions > Select Region Boundaries**.
   
   or
   
   Select the **Select Boundary** tool.
   
   The cursor changes to the Select Boundary pointer in the View window.

2. Select the boundary line to be removed.
   The line is highlighted blue.

3. Either:
   Select **Edit > Delete**.
   
   or
   
   Press **Delete**.
   The two regions separated by the boundary line are merged.

**Related Links**

- **D. Regions menu** (on page 1165)

D. Changing the orientation of a region

1. Select the **Concrete Slab | Regions** page.
   
   The **Regions** table opens.
   
   2. Select the Orientation cell for the Region you want to reorient.
   
   3. Specify a rotation value for the local x-axis.
Note: The default slab local x-axis is used as the default for each region.

4. Press <Return>.

D. Design menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design Options</td>
<td>Opens the Design Options dialog (on page 1168), which is used to control the physical members to be included in a design command.</td>
</tr>
<tr>
<td>Design Now</td>
<td>Designs the current group according to the settings in the Design Options dialog (on page 1168).</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> In the case of Concrete Slab design, the Design &gt; Design menu item designs the selected slab (no options are available).</td>
</tr>
</tbody>
</table>

The menu is available in the modes:

- Member Design
- Slab Design

D. (Members) Design Options dialog

Used to control the physical members to be included in a design command. The current Design Group and associated Design Brief are displayed at the top of the dialog for reference.

Opens when Design > Design Options (on page 1168) is selected.
Available list  Contains all members added to the current Design Group.

Selected list  Members which will be included in the pending design.

<table>
<thead>
<tr>
<th>Tool icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>Adds the member(s) selected in the Available list to the Selected list.</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Adds all members from the Available list to the Selected list.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Removes the selected member(s) from the Selected list.</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Removes all member(s) from the Selected list.</td>
</tr>
</tbody>
</table>

**Note:** By default, no load cases or combinations are selected.

**OK**  Saves the member selection and closes the dialog.

**Cancel**  Closes the dialog without saving changes.

**Design**  Initiates the member design for Selected members.

**Help**  Opens the STAAD.pro help window.
D. Check menu

This menu contains the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check Parameters</td>
<td>This command re-opens the Collapse Check Setup dialog (on page 1170) that is displayed when the Earthquake Mode is first entered so that the settings can be redefined. Earthquake page (on page 1216) for more information.</td>
</tr>
</tbody>
</table>

The menu is available in the modes:

- Earthquake Mode

D. Collapse Check Setup dialog

Used to specify seismic parameters for performing a collapse check.

Opens when:

- The Earthquake mode (on page 1216) is selected, or
- Check > Check Parameters... is selected.
**Figure 140: The Collapse Check Setup dialog for ACI 318-05 and EC8-2004 codes, respectively**

**Design Code**
Select the appropriate code governing seismic design: ACI (99 or 2005), Eurocode 8, or TS500.

**National Annex**
(EC8-2004 only) Select the national annex to use with Eurocode 8.

**Ductility Level**
Select the level of ductility for the structure overall.
- ACI 318 and TS 500: Either level 1 or 2.
- EC8: Select either Ductility Class Medium (DCM) or Ductility Class High (DCH).
Earthquake Load case
Select the seismic load case from the list of primary and combination results in the pull-down list.

Check Reinforcement detailing rules for Ductility
(EC8-2004 only) Select this option to.

Curvature ductility factor
(EC8-2004 only)

Check Now
All the joints which have beams and columns connected are checked

Cancel
Closes the dialog without checking for collapse under seismic load.

D. Results menu
This menu contains the following command:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design Results Setup</td>
<td>Opens the Design Results Setup dialog (on page 1173), which is used to control the display of results by design group and color.</td>
</tr>
<tr>
<td>Individual Graphs</td>
<td>Opens a Member Graph window (on page 1175) for the selected element or member. Each window can show results of multiple force types and multiple load cases, combinations and/or envelopes.</td>
</tr>
<tr>
<td>Tip: To change or add load cases or lines to the graph, use the Diagrams command from the View menu.</td>
<td></td>
</tr>
<tr>
<td>Main Reinforcement Diagram</td>
<td>Displays the result of the design on the current member. The diagram is divided into parts which can be resized by dragging the separator. A Beam Design produces a different diagram to a column design.</td>
</tr>
<tr>
<td>Shear Reinforcement Diagram</td>
<td>Displays the shear result of the design on the current member. The diagram is divided into three parts that can be resized by dragging the separator. A Beam Design produces a different diagram to a column design.</td>
</tr>
<tr>
<td>Plan View</td>
<td>Toggles the view on the top section of a main or shear reinforcement diagram to display the reinforcement from an elevation view to a plan view.</td>
</tr>
<tr>
<td>Beam Spans</td>
<td>Opens the Beam Spans table (on page 1177), which provides member span and support information.</td>
</tr>
<tr>
<td>Main Reinforcement</td>
<td>Opens the Main Reinforcement table (on page 1179), which shows the design moments, required steel areas and provided steel bars for each location along the beam that was checked.</td>
</tr>
<tr>
<td>Menu item</td>
<td>What it does</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Shear Links</td>
<td>Opens the Shear Links table (on page 1182), which shows the shear forces and stresses at the design locations along with the required steel area.</td>
</tr>
<tr>
<td>Shear Zones</td>
<td>Opens the Shear Zones table (on page 1183), which displays the results of the shear design.</td>
</tr>
<tr>
<td>Deflection</td>
<td>Opens the Span/Depth Ratio table (on page 1184), which is used to verify the limit of effective depth divided by the actual span length is not exceeded.</td>
</tr>
<tr>
<td>Scheduled Bars</td>
<td>Opens the Member # Scheduled Bars table (on page 1186), which is used to specify individual covers and link sizes for each span, as well as verify the support definitions.</td>
</tr>
<tr>
<td>Member Summary</td>
<td>Opens the Summary table (on page 1187) for the group design, which displays the pass/fail status of all members in the Design Group.</td>
</tr>
<tr>
<td>Clear Results</td>
<td>Deletes the results of the current design.</td>
</tr>
<tr>
<td>Edit Bar Cage</td>
<td>Opens the M# Bar Positions table (on page 1181), which is used to edit the size and arrangement of reinforcing bars in the column reinforcement bar cage.</td>
</tr>
</tbody>
</table>

The menu is available in the modes:

- Member Design
- Slab Design
- Earthquake

D. Design Results Setup dialog
Used to control the display of results by design group and color.

Opens when Results > Design Results Setup (on page 1172) is selected.
Groups tab

Choose the design groups for which results are to be displayed in the graphics window.

**Available list**  
The Available list shows the groups for which results may be displayed.  
Select a group by clicking on it, then transfer it to the Selected list by clicking on the > button.  
Select more than one at once by holding down the **<CTRL>** key while selecting.  
All the groups in the Available list can be selected by clicking on the >> button.

**Selected list**  
The Selected list shows the groups for which results are displayed.  
To remove a group from the Selected list, highlight it by clicking on it, then click on the < button to return it to the Available list.  
All the groups can be removed from the Selected list by clicking on the << button.

Colour Coding tab

The color coding of the results display can be configured.
Colour
Select the “None” check box and no results are shown on the graphic.

Pass Fail
Select the “Pass/Fail” check box to activate the left hand option list. Select the options to display by picking the check boxes.

To reconfigure the colors used for the various options, pick one of the color blocks next to the option list. The Design Results Pass/Fail Colours dialog opens. Pick the item to be changed from the pull down list, then select the color to be used for displaying this item from the palette displayed.

Select the “Efficiencies” check box to activate the right hand option list.

To reconfigure the colors used for the various options, pick on one of the color blocks next to the option list. The Design Results Efficiency Colors dialog opens. Pick the item to be changed from the pull down list, then select the color to be used for displaying this item from the palette displayed.

OK
Changes the group or color settings and closes the dialog.

Cancel
Closes the dialog without applying any changes.

Apply
 Applies selected changes.

Help
Opens the STAAD.Pro help window.

D. Member Graph window
Show results of multiple force types and multiple load cases, combinations and/or envelopes.

Opens when Results > Individual Graphs (on page 1172) is selected.
Right Click Pop-up Menu

<table>
<thead>
<tr>
<th>Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy Picture</td>
<td>Copies the graph to the Windows clipboard, so that it may be pasted into other programs that support pasting of images.</td>
</tr>
<tr>
<td>Take Picture</td>
<td>Opens the Picture # dialog (on page 1120), which is used to save the graph to the photo album.</td>
</tr>
<tr>
<td>Diagrams...</td>
<td>Opens the Diagram (graph) dialog (on page 1176), which is used to control the display of load cases and internal forces displayed in the graph.</td>
</tr>
<tr>
<td>Follow View Selection</td>
<td>When this option is toggled on, the Member Graph updates with the member selection in the active view window.</td>
</tr>
<tr>
<td>Follow Current Member</td>
<td></td>
</tr>
</tbody>
</table>

D. Diagram (graph) dialog

Used to control the display of load cases and internal forces displayed in the graph.

Opens when Diagrams... is selected from the right click pop-up menu in the Member Graph window (on page 1175).
Dialog Box options

**Load Cases list** Select the load cases for which the graphs are to be drawn.

**Tip:** More than one load case can be selected by holding down the CTRL key.

**Colours…** Click on this button to customize the colours of the graphs. This button displays the Graph Colours dialog. Select a graph from the drop-down list and then set its colour by clicking on the palette.

**Forces** Select the forces graphs to be drawn.

**OK** Updates the graph and closes the dialog.

**Cancel** Closes the dialog without making any changes to the graph.

**D. Beam Span table**
Used to specify individual covers and link sizes for each span, as well as verify the support definitions.

Opens when:

- **Results > Beam Spans** is selected, or
- the [Concrete Members | Main Rft. page](on page 1207) is selected

**Spans tab**
Used to setup individual covers and link sizes for each span. The values for the Covers and Link Size are initially set by the values from the Design Brief, but can be edited and set separately for each span.
**Design**

**D. Concrete Design**

![Supports tab](image)

**Supports tab**

Used to define the size and type of support that can be used for shear enhancement. Both the Support Type (No support, Simple or Fixed) and Support Width can be set.

![Table Right-Click Pop-Up Menu](image)

**Table Right-Click Pop-Up Menu**

</tr>
</tbody>
</table>

**D. Main Reinforcement table**

Shows the design moments, required steel areas and provided steel bars for each location along the beam that was checked.

Opens when:

- **Results > Main Reinforcement** (on page 1172) is selected, or
- the Concrete Members | Main Rft. page (on page 1207) is selected

The Hoggging and Sagging tabs display the selected reinforcement under negative and positive bending, respectively.

**Note:** This table is not editable. The values displayed are taken from the design of the current member.
Values that are displayed in green indicate sections where the reinforcement that is provided is to meet the minimum reinforcement requirements, as the design moment is too small. Values that are displayed in red indicate that not all the design requirements were met for the provided reinforcement.

**D. M# Bar Positions table**

Used edit the size and arrangement of reinforcing bars in the column reinforcement bar cage.

Opens when **Results > Edit Bar Cage** (on page 1172) is selected.

![M# Bar Positions Table](image)

The following columns of data are used in each row:

- **Position** - Select the side or top bar position for
- **Dist. to C/L** - Specify the center-line to center-line distance between bars.
- **Size** - Select a bar size to use for the longitudinal bars in this cage.
- **Number** - Number of bars in this cage. This value is not user editable and is defined by the **Position** type.

**Apply** Update the member design with the changes made to the bar positions.

**Reset** Undo all changes made and revert to the program selected arrangements.

**Related Links**

- **D. Adding a new bar cage** (on page 1181)

#### D. Drawing menu

This menu contains the following commands:

The menu is available in the modes:

- Member Design
- Slab Design

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export to DXF</td>
<td>Opens the [Export to Drawing dialog](on page 1188), which is used to create a DXF file of the current member (please contact Bentley Technical Support for more information on this feature). The file contains elevations, sections and a bending schedule.</td>
</tr>
</tbody>
</table>

**D. Export to Drawing** dialog

Used to create a DXF file of the current member that can be read into the AutoCAD application Multi-RC (please contact Bentley Technical Support for more information on this product). The file contains elevations, sections and a bending schedule.

For DXF output, the concrete outlines, covers, and center lines are all output as simple lines to appropriate layers. The bars are sent as polylines, again to separate layers. The schedule is not exported, but may be printed from the normal report setup.

Opens when:

- **Drawings > Export to DXF** is selected, or
- **The Concrete Member | Drawing page** is selected.
Preview window  Shows how the member will appear when imported into Multi-RC with the current settings.

Size and Scale  This sets the size of paper that the drawing is to be imported into and scale of the drawings to be generated.

Export Format  Select either .DXF or MultiREBAR drawing format.

Title Block  This is used for guidance so that the user can position the drawing without encroaching the space that is provided for title blocks in the final drawing.

Cut Beam after span  When the current beam is a multiple span, then the beam can be cut at support locations and the next section is then continued below.

Spacing  There are three values that are used to locate the drawings onto the drawing sheet. The First Span Left and First Span Top locate the top left corner of the first span relative to the top left corner of the drawing. The value Separation Constant defines the distance between sections of a beam that have been cut using the Cut Section as outlined above.

OK  Closes the dialog and opens a Save As dialog (on page 1190) for specifying a name and location for the drawing file.

Cancel  Closes the dialog without creating a drawing file.
D. Save (Drawing) As dialog
Used to name and select a location when saving a .DXF created from the Export to Drawing dialog.

Controls in this dialog are analogous to common Windows Save As dialogs.

**D. Mode menu**

This menu contains the following commands:

The menu is available in the modes:

- Design Layer
- Member Design
- Slab Design
- Earthquake

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design Layer</td>
<td>Switches the operating mode of Concrete Design to the Design Layer mode (on page 1202) and page layout to the Job Information Page.</td>
</tr>
</tbody>
</table>
| Member Design       | This switches the operating mode of Concrete Design to the Concrete Member mode (on page 1207).  
                        | There must be at least one Member Design Group defined to enter this mode. If the current design group is a Member Group, the mode is entered with this group. If the current design group is a Slab Group, then the mode is entered with the first Member Design Group.  
                        | The page layout is determined by the design code associated with the current design group. |
### Menu item | What it does
--- | ---
Slab Design | This switches the operating mode of Concrete Design to the Concrete Slab mode (on page 1212).

There must be at least one Slab Design Group defined to enter this mode. If the current design group is a Slab Group, the mode is entered with this group. If the current design group is a Member Group, then the mode is entered with the first Slab Design Group.

The page layout is determined by the design code associated with the current design group.

Earthquake | This switches the operating mode of Concrete Design to the Earthquake mode (on page 1216).

In this mode, the junctions of all the beams and columns designed with the Concrete Design can be checked to one of a number of design codes.

Page Control | Toggles the Page Control (on page 1202) menu on the left hand side of Concrete Design.

### D. Window menu

This menu contains the following commands:

The menu is available in the modes:

- Design Layer
- Member Design
- Slab Design
- Earthquake

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cascade</td>
<td>Arranges the windows in Concrete Design in an overlapping pattern so that the title bar of each window remains visible.</td>
</tr>
<tr>
<td>Tile Horizontal</td>
<td>Arranges the windows in Concrete Design so that all the windows which are not minimized do not overlap and are as wide as possible. Any minimized window icons are arranged in a gap underneath the tiled windows.</td>
</tr>
<tr>
<td>Tile Vertical</td>
<td>Arranges the windows in Concrete Design so that all the windows which are not minimized do not overlap and are as tall as possible. Any minimized window icons are arranged in a gap underneath the tiled windows.</td>
</tr>
</tbody>
</table>
### Menu item | What it does
--- | ---
Arrange Icons | Arranges the icons of any minimized Concrete Design windows into rows across the bottom of the MDI window. This command does not affect the size or position of any open windows.
Structure Only | Closes all Concrete Design windows for the active structure except for a single whole structure window. If a whole structure window is not currently open, then RC Designer creates a new one.

### D. Help menu
This menu contains the following commands:
The menu is available in the modes:
- Design Layer
- Member Design
- Slab Design
- Earthquake

<table>
<thead>
<tr>
<th>Menu item</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contents</td>
<td>Displays the contents page of the Concrete Design Help system. The Help system contains sections for Overview, Engineering Information, Using RC Designer step-by-step, Options and a Command Reference. When looking through Help, the Contents page can be returned to by clicking on the Contents button in the Concrete Design Help window.</td>
</tr>
<tr>
<td>About STAAD.Pro RC</td>
<td>Opens the About STAAD.Pro RC dialog (on page 1192) for the program, which provides the version number and copyright information for the software.</td>
</tr>
</tbody>
</table>

D. About STAAD.Pro RC dialog
Provides the version number and copyright information for the software.
Opens when Help > About is selected.
D. Toolbars

Concrete Design displays two toolbars at the top of the screen by default.

The top toolbar, called the **Standard toolbar** (on page 1193), is consistent. The second toolbar, called the Page/Mode Automatic toolbar, is dependent upon the current page.

A third toolbar, called the **Labels toolbar** (on page 1201), may be turned on, as well.

### D. Standard Toolbar

The Standard toolbox contains icons that enable quick access to commonly used pull-down menu items.

**Note:** View, Zoom, Rotation, and Margin can also be finely controlled using the **Orientation dialog** (on page 1133).

<tr>
<td><img src="icon" alt="Property Labels" /></td>
<td>Draws section property reference labels (toggle) in the active window</td>
</tr>
<tr>
<td><img src="icon" alt="Section Names" /></td>
<td>Draws section name labels (toggle) in the active window</td>
</tr>
<tr>
<td><img src="icon" alt="Orientation Symbols" /></td>
<td>Draws orientation symbol labels (toggle) in the active window</td>
</tr>
<tr>
<td><img src="icon" alt="Axes Diagram" /></td>
<td>Draws the axis key diagram (toggle) in the active window</td>
</tr>
</tbody>
</table>
### D. Toolbar Pop-up Menu

Used to quickly toggle the display of toolbars and access toolbar controls.

Opens when a right-click is made on any window toolbar.

<table>
<thead>
<tr>
<th>Menu entry</th>
<th>What it does</th>
<th>Same effect as selecting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard</td>
<td>Toggles the display of the Standard toolbar (on page 1193).</td>

</tr>
<tr>
<td>Page/Mode</td>
<td>Toggles the display of the context sensitive Page/Mode Automatic toolbar (on page 1195).</td>
<td></td>
</tr>
<tr>
<td>Labels</td>
<td>Toggles the display of the Labels toolbar (on page 1201).</td>
<td></td>
</tr>
<tr>
<td>Toolbars...</td>
<td>Opens the Toolbar Setup dialog (on page 1137).</td>
<td>View &gt; Toolbars</td>
</tr>
</tbody>
</table>

### D. Page Control Layout

As with STAAD.Pro, Concrete Design uses a Page Control interface. Each mode has “Pages” that set the layout of the application.

**Tip:** The Page Control display can be toggled by selecting **Mode > Page Control** (on page 1190).

The Page Control menu is comprised of two sets of the buttons, the left side set which indicate the Mode and the right side set which are the Pages. The actual Pages that are displayed are dependent upon the current Mode.

#### D. Design Layer Mode

There are five Pages in the Design Layer. Each page lays out the screen so that you can easily step through the process of setting up and checking data. They are read from the bottom left corner upwards. The pages in the Design Layer are:
<table>
<thead>
<tr>
<th>Page control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Job Information</td>
<td>The Job Information Page is to allow the user to add additional information into the <strong>D. Job Information dialog</strong> (on page 1109). When Concrete Design is first opened, the Job Information dialog is populated with the Job Information entered in STAAD.Pro.</td>
</tr>
<tr>
<td>Envelopes</td>
<td>Used to define envelopes of basic load cases and combination load cases that have been defined in the analysis model. Envelopes are required for Beam Design Briefs. When the Envelopes page is selected, the <strong>D. Envelopes table</strong> (on page 1204) opens in the right of the RC Designer window.</td>
</tr>
<tr>
<td>Members</td>
<td>Designs of beams and columns are performed on physical members which are made of one or more analytical beam parts. The Members Page is to allow the user to combine together a number of individual beam elements and create members. All designs are performed on these members. See <strong>D. Design of Members and Slabs</strong> (on page 1008) for information on how to create a physical member. A list of members, including their analytical parts are listed in the <strong>D. Members table</strong> (on page 1151) on the right of the screen.</td>
</tr>
<tr>
<td>Slabs</td>
<td>Designs of slabs are performed on slab objects which are made of one or more finite element (plate element) parts, which can be later broken down again into design regions. The Slabs Page is to allow the user to combine together a number of individual finite elements and create members. All slab designs are performed on these slab objects. See <strong>D. Design of Members and Slabs</strong> (on page 1008) for information on how to create a slab. A list of all defined slabs, with a summary of their thicknesses, net and gross areas, number of holes and number of plates, are listed in the <strong>Slabs table</strong> (on page 1153) on the right of the screen.</td>
</tr>
</tbody>
</table>
The Groups / Briefs Page is to allow the user to define Design Groups and setup the parameters in Design Briefs. Any number of Design Groups and Design Briefs can be defined, however it is important to note that it is only possible to enter the Design Mode if the security device supports the design code associated with the Design Brief of the current Design Group.

Once one or more Design Groups have been created, the Design Mode (on page 1207) can be entered and the Design Brief of current design group will determine the page layout.

See D. Design Briefs (on page 1010) and D. Design Groups (on page 1012) for additional information on using this page.

D. Envelopes table
Used to manage load envelopes used for element design.

Opens when:

- the Des. Layer | Envelopes page (on page 1202) is selected, or
- The Envelopes table tool is selected.

- Envelopes list Displays the number and title for each envelope used in the current model.
- New Env. Click to open the New Envelopes dialog (on page 1204), which is used to name a new load envelope. Once you have specified a name, the Define Envelopes dialog (on page 1205) will open to define the load cases for the new envelope.
- Edit Env. Opens the Define Envelopes dialog (on page 1205), which is used to modify, rename, or remove load envelopes from the model.
Opens when New Env. is clicked on the Envelopes table (on page 1204).

E# Specify a name for the new load envelope. This will be used to identify the envelope in RC Designer and will be referenced in Reports.

OK Add a new envelope with the specified name and open the Define Envelope dialog (on page 1205).

Cancel Close the dialog without creating a new envelope.

D. Define Envelope dialog
Used to modify, rename, or remove load envelopes from the model.

Opens when:
- the Edit Env. button is clicked on the Envelopes table (on page 1204), or
- when the Define Envelope tool is selected.

*Load Cases*
Displays a list of all basic load cases and load combinations included in the STAAD.Pro input file.

*Envelope*
Select the Envelope number and title from the list of all current envelopes. All included load cases and combinations considered in this envelope is displayed in the list below.
This selection will be set to either a newly created envelope or the current envelope selected in the Design Layer toolbar (on page 1195).

Add basic load cases or combinations to the load envelope using the list transfer tools:

<table>
<thead>
<tr>
<th>Tool</th>
<th>What it Does</th>
<th>Same Effect as</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>Add the selected item(s) in the Load Case list to the Envelope list.</td>
<td>Double clicking an item in the Load Case list.</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Add all currently displayed items in the Load Case list to the Envelope list.</td>
<td></td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Remove all items in the Envelope list.</td>
<td></td>
</tr>
<tr>
<td>&lt;</td>
<td>Remove the selected item(s) in the Envelope list.</td>
<td>Double clicking an item in the Envelope list.</td>
</tr>
</tbody>
</table>

Show Combinations Only
Select this option to limit the Load Cases list to load combinations only (basic load cases will not be displayed).

OK
Applies the changes to the selected Envelope load and closes the dialog.

Cancel
Closes the dialog without making any changes to the load envelope.

Note: If the Define Envelopes dialog was opened through the New Envelope dialog, the newly created envelope is not removed by not loads will be added.

New
Opens the New Envelope dialog (on page 1204), which is used to create a new load envelope.

Rename
Opens the Rename Envelope dialog (on page 1206), which is used to specify a new title for the currently selected envelope.

Delete
Used to remove the currently selected Envelope from the model. A warning dialog opens to verify you want to proceed.

Caution: This action cannot be undone.

D. Rename Envelope dialog
Used to rename an existing load envelope.
Opens when Rename is clicked in the Define Envelope dialog box (on page 1205).
Old Name  Displays the existing name of the envelope selected for renaming.
New Name  Specify a new name to use for the selected envelope.
OK  Updates the envelope name and closes the dialog.
Cancel  Closes the dialog without changing the envelope name.

D. Concrete Member Mode

The layout of the pages of the Concrete Member design mode is dependent on the Design Code associated with the current Design Group.

Concrete Beam pages

A Design Group associated with an Beam Brief will have a Concrete Member Mode containing seven pages. Each page lays out the screen so that the user can easily step through the process of setting up and checking data. They are read from the bottom left corner upwards.

<table>
<thead>
<tr>
<th>Page control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design</td>
<td>Similar in layout to the Summary Page, but on entering the page the Design Options dialog (on page 1168) opens allowing the beam design to be initiated. The &lt;Design Group&gt; Summary table (on page 1187) displays the status of the design.</td>
</tr>
<tr>
<td>Summary</td>
<td>Displays the summary of the design of the current beam Design Group. The page is laid out with a Structure View window on the left and on the right is the Member Summary Table (on page 1187) displaying the status of the members in the current group above the Beam Spans Table (on page 1177) displaying the supports and resulting spans defined for members in the current group.</td>
</tr>
</tbody>
</table>
### Page control

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Main Layout</strong>&lt;br&gt;Graphically displays the main reinforcement resulting from the design of the current beam Design Group.&lt;br&gt;The page is laid out with a Structure View window on the left and a <strong>Main Reinforcement Diagram</strong> of the current member on the right. The current member can be changed by selecting it from the pull-down menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window.&lt;br&gt;&lt;br&gt;Note: The summary of the reinforcement requirements is displayed in the Main Reinforcement Page.</td>
</tr>
<tr>
<td><strong>Main Reinforcement</strong>&lt;br&gt;Displays the main reinforcement resulting from the design of the current beam Design Group as numerical data.&lt;br&gt;The page is laid out with a Structure View window on the left and on the right the <strong>Beam Spans Table</strong> (on page 1177) of all the members in the current design group, above the <strong>Main Reinforcement Table</strong> (on page 1179) of the current member on the right. The current member can be changed by selecting it from the pull-down menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window.</td>
</tr>
<tr>
<td><strong>Shear Layout</strong>&lt;br&gt;Displays the shear reinforcement resulting from the design of the current beam Design Group.&lt;br&gt;The page is laid out with a Structure View window on the left and the <strong>Shear Reinforcement Diagram</strong> of the current member on the right. The current member can be changed by selecting it from the menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window.&lt;br&gt;&lt;br&gt;The <strong>Shear Reinforcement Diagram</strong> displays the shear result of the design on the current member. The diagram is divided into three parts that can be resized by dragging the separator. A Beam Design produces a different diagram to a column design.</td>
</tr>
</tbody>
</table>
### Page control

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shear Reinforcement</td>
<td>Displays the shear reinforcement resulting from the design of the current beam Design Group as numerical data. The page is laid out with a Structure View window on the left and on the right the Shear Links Table (on page 1182) above the Shear Zones Table (on page 1183), both for the current member. The current member can be changed by selecting it from the pull-down menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window.</td>
</tr>
<tr>
<td>Drawing</td>
<td>Used to export member detail drawings and to display a summary of the scheduled bars for the current beam design group. The Bar Schedule Table (on page 1186) opens to the right of the Whole structure View window. This provides a summary of the reinforcing bars used in the current member. When the drawing page is selected, the Export to Drawing dialog (on page 1188) is automatically opened with the current beam information loaded. <strong>Note:</strong> For TS500 beam groups, this tab is labeled Schedule and the Export to Drawing dialog does not open when the page is selected.</td>
</tr>
</tbody>
</table>

### Column Design pages

A Design Group associated with a Column Brief will have a Concrete Member Mode containing seven pages. Each page lays out the screen so that the user can easily step through the process of setting up and checking data. They are read from the bottom left corner upwards.

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Summary</td>
<td>Displays the summary of the design of the current column Design Group. The page is laid out with a Structure View window on the left and on the right is the Member Summary Table (on page 1187) displaying the status of the members in the current group.</td>
</tr>
<tr>
<td>Page control</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Input        | Displays the design settings of the members in the current column Design Group.  
The page is laid out with a Structure View window on the left and the **Member Design Data table** (on page 1211) on the right. This table is used to override the settings of the design Brief for individual members. The effective length factors, braced directions and cover can be set for each column in the group separately. |
| Design       | Similar to the Summary Page, but on entering the page the **Design Options dialog** (on page 1168) opens allowing the column design to be initiated.  
The **<Design Group> Summary table** (on page 1187) displays the status of the design. |
| Main Layout  | Graphically displays the main reinforcement resulting from the design of the current column Design Group.  
The page is laid out with a Structure View window on the left and a main reinforcement diagram of the current member on the right. The current member can be changed by selecting it from the pull-down menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window. |
| Shear Layout | Displays the shear reinforcement resulting from the design of the current column Design Group.  
The page is laid out with a Structure View window on the left and a Shear reinforcement diagram of the current member on the right. The current member can be changed by selecting it from the pull-down menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window. |
| Results      | Displays the reinforcement resulting from the design of the current column Design Group as numerical data.  
The page is laid out with a Structure View window on the left and a Main Reinforcement Table above the Shear Reinforcement Table for the current member on the right. The current member can be changed by selecting it from the pull-down menu on the second toolbar or by clicking on a member in the current Design Group on the Structure View window. |
D. Entering the Concrete Member Design Mode

1. Either:
   
   **Modes > Concrete Member.**
   
   or
   
   the Concrete tab in the Page Control.
   
   The **Concrete Member | Summary** page is displayed.

D. (Column) Member Design Data table

Used to override the settings of the design Brief for individual members. The effective length factors, braced directions and cover can be set for each column in the group separately.

Opens when the **Concrete Member | Input page** (on page 1207) is selected for a column design group.

<table>
<thead>
<tr>
<th>Length</th>
<th>Physical member length as determined by the formed physical member.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Physical member type, assigned by the Design Group associated Design Brief.</td>
</tr>
<tr>
<td>Eff. Len. Factors</td>
<td>The Effective Length factors for major and minor axis bending. These default to the values assigned to the associated design brief. A numeric value can be entered in the cell if a different value is required.</td>
</tr>
</tbody>
</table>
**Design**

**D. Concrete Design**

| **Braced** | The major and minor axis bending braced status is selected using this options. A check is placed if the member is braced in the bending direction. The braced conditions can be changed. |
| **Covers** | The concrete cover dimensions are listed here. The default cover value assigned to the associated design brief are used. A numeric value can be entered if a different value is required. |
| **Link Size** | The size of reinforcing bar is selected from a list here. |

**D. Concrete Slab pages**

The layout of the pages of the Concrete Member design mode is dependent on the Design Code associated with the current Design Group.

Design Codes that are currently available are:

- **BS 8110 Slab** (on page 1260)
- **ACI 318-05/ 318M-05 Slab** (on page 1235)

The engineering information on a BS8110 design can be found in section 3.4.4 (on page 1081)

**Table 83: Sub-pages in the Concrete Slab page**

<table>
<thead>
<tr>
<th>Page name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Summary</td>
<td>Used to view design reinforcement plots, and view tabulated output that lists design moments and bar details with respect to Region axis. Plots can be created for both required reinforcements or bar spacing. Direction settings cover top and bottom reinforcement with respect to local axis of the Region/Slab. You may generate filled or lined plots for all outputs.</td>
</tr>
<tr>
<td>Displacement</td>
<td>Used to evaluate deflection of the slab and produce contour plots. You may draw a Result Line on the plot and view the deflection along the line. The result line can be drawn parallel to the slab axis or in any other direction.</td>
</tr>
<tr>
<td>Moments</td>
<td>Used to interrogate design effects and create plots much the same way as the displacement page.</td>
</tr>
</tbody>
</table>
Regions

Used to divide a Design Slab into Regions, which with its own local axis setting. This page also opens the Regions table (on page 1166). Each Region may represent an area of the slab where you may want to change bar layout.

Note: By default, each ‘Slab’ has one coincident ‘Region’. Designs are carried out for each ‘Region’ and with respect to the Region’s local axis setting.

Regions can be defined in a number of ways. You may draw lines from boundary nodes of elements, or, you may highlight a boundary line and insert a node and the use it for region definition.

Design

Opens the Design Options dialog (on page 1214), used to initiate the design of all regions as per design brief of the slab and local axis of each region.

Related Links

- D. BS8110 Slab Design Principles (on page 1085)

D. Using the Concrete Slab | Displacements page

The Result Line Graph displays a cross section result of the results displayed on the Slab.
A. Select the results to display from this drop-down list or by selecting View > Diagram (on page 1121).

B. A Results Line is drawn onto the slab surface.

**Note:** The graph is set to Filled in the Analysis Contour diagram options (on page 1144).

C. The selected results are displayed along the result line in the Result Line Graph. Numerical results are displayed in the table below.

The Result Line graph and table can also be opened when Result Line > Result Line Graph is selected.

D. Regions table

Used to display and edit details for slab design regions.

Opens when the Concrete Slab | Regions page is selected.

---

**Related Links**

- [D. Changing the orientation of a region](#) (on page 1167)

**D. (Slab) Design Options** dialog

Used to initiate the design of all regions as per design brief of the slab and local axis of each region. Displays all the regions in the active Slab.

Opens when the Concrete Slab | Design page is selected.
**Design**

**D. Concrete Design**

![Design Options dialog](image)

**Note:** All design moments are resolved with respect to local axis of each region before reinforcement calculation proceeds.

- **Regions** Displays the slab regions which will be included in the pending design.
- **OK** Closes the dialog.
- **Cancel** Closes the dialog.
- **Design** Initiates a slab design and closes the dialog.
- **Help** Opens the STAAD.Pro help window.

**D. Entering slab design mode**

1. Either:
   - select **Modes > Slab Design**
   - or
   - select the **Concrete Slab** page.

**D. Changing plot settings**

1. Either:
   - select **View > Diagram**
   - or
   - right click anywhere in the View window and select **Diagram** from the pop-up menu.
The **Diagrams dialog box** (on page 1144) opens with new tabs for slab display.

### D. Earthquake page

When this mode is selected, a **Collapse Check dialog** (on page 1170) is opens. This dialog is used to set the code and code parameters for the seismic load.

#### Table 84: Sub-pages in the Earthquake page

<table>
<thead>
<tr>
<th>Page name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moment</td>
<td>Opens the [Moment Collapse Check table](on page 1216).</td>
</tr>
<tr>
<td>Deflection</td>
<td>Opens the [Story Collapse Check table](on page 1216).</td>
</tr>
<tr>
<td>Shear</td>
<td>Opens the [Shear Collapse Check table](on page 1217).</td>
</tr>
<tr>
<td>Reinforcement</td>
<td>Opens the Reinforcement Checks - Beams table and Reinforcement Checks - Columns table.</td>
</tr>
</tbody>
</table>

#### D. Moment Collapse Check table

This feature is not yet documented.

Opens when the [Earthquake | Moment page](on page 1216) is selected.

![EXAMP09 - Moment Collapse Check](image)

#### D. Story Collapse Check table

This feature is not yet documented.

Opens when the [Earthquake | Deflection](on page 1216) page is selected.
D. **Shear Collapse Check** table

This feature is not yet documented.

Opens when the [Earthquake | Shear page](on page 1216) is selected.

D. **Reinforcement Checks - Beams** table

This feature is not yet documented.

D. **Reinforcement Checks - Columns** table

This feature is not yet documented.

D. **Status Bar**

Provides prompts and context-sensitive assistance.
**Selected tool prompt**
Shows a tip for using the tool the mouse pointer is hovering over.

**Colour: <scheme>**
Displays the currently selected color scheme. The color scheme is selected in the Colour Manager dialog (on page 1132).

**Load case title**
Displays the title of the currently selected load case. The load case can be changed using the Load Case selector found in the Page/Mode Automatic toolbar (on page 1195) on various pages.

### D. View Window Controls

The view window contains some view controls in the lower, right corner.

Click E to zoom to the extent of the structure view.

![Zoom controls](image)

Holding the `<CTRL>` key down and pressing one of the direction keys on the keyboard will rotate the structure on the original and zoomed windows.

**Tip:** To quickly open a zoom window, select the Zoom tool on the Standard toolbar.

To move the position of the zoom window use either the scroll bars on the window, the cursor keys on the keyboard, or the Viewpoint tools on the toolbar. The cursor keys and the viewpoint buttons move the viewing point around the structure.

### D. Design Brief dialogs

Used to enter code-specific parameters for a member or slab design brief. The dialog contents is dependent on the code and member type selected.

**D. ACI 318-99 & ACI 318-05 Member Briefs**

**D. ACI 318-99 Beam Brief** dialog
The ACI Beam Design Brief has the following tabs for setting out the design parameters:

- General tab
**Minimum Covers**
Set the cover to the top, bottom and sides of the beams (in inches).

**Concrete**
Set the strength (in ksi), maximum aggregate size (in inches) and option to use lightweight concrete, in which case either the Tensile fct should be defined (in ksi) or the Lightweight Factor as a fraction.

**Forces**
Set the option whether the torsion forces should be designed for and whether the design should be taken at the face or center-line of the support.

**Envelope**
The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

**Divide Beam**
Set the minimum number of segments that each member should be divided into for calculating the reinforcement (must be at least four).

Main Reinforcement tab
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in inches) between the top 2 layers.

Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in inches) between the bottom 2 layers.

Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

Specify the steel strength (in ksi) and whether the steel is epoxy coated.

Select whether the development length is defined from cl 12.2.2 or cl 12.2.3.

Click the Bending Dimensions… button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Note: Bar sizes include: #3, #4, #5, #6, #7, #8, #9, #10, #11, #14, #18

Shear Reinforcement tab
Design Shear For

Select the option to design the shear reinforcement up to the **Center Line of Column** (support), **Column Face** (edge of support), or the distance 'd' from the **Column Face**. Note that the column or support face is defined in the Spans Table.

Select whether to **Include Axial Load Effects** in the longitudinal reinforcement.

Shear Bar Criteria

Specify the Bar Strength to use for shear reinforcement (in ksi).

The bar size to use from the pull-down list of available sizes.

The minimum number of shear legs, 2, 3, 4, 5 or 6.

The minimum spacing between links to consider, if a smaller distance is required, then the number of legs will be increased.

Set whether the stirrups are defined as Closed or Open for the schedule.

Click the **Bending Dimensions...** button to open the **Bending Dimensions dialog** (on page 1157), which is used to specify the bending dimensions for each bar size.

**Note:** Bar sizes include: #3, #4, #5, #6, #7, #8, #9, #10, #11, #14, #18

**OK**  Accepts parameters on all dialog tabs and closes the dialog.

**Cancel**  Closes the dialog without saving any changes.

**Apply**  Saves changes made in the dialog. Only available if changes have been made.

**Help**  Opens the STAAD.Pro help window.

**D. ACI 318-99 Column Design Brief** dialog

The ACI Column Design Brief has the following tabs for setting out the design parameters:
General tab

**Concrete** Specify the strength (in ksi), maximum aggregate size (in inches) and option to use lightweight concrete, in which case either the Tensile fct should be defined (in ksi) or the Lightweight Factor as a fraction.

Specify the cover to the shear links (in inches)

Specify the maximum size of aggregate (in inches)

**Main Bars** Specify the strength of the main bars (in ksi), the range of sizes to consider from minimum to maximum sizes and the bending dimensions.

**Links** Specify the strength of the link bars (in ksi), the minimum size link to consider and the bending dimensions.

For circular columns select whether the design should specify tie or spiral reinforcement.

**Note:** Bar sizes include: #3, #4, #5, #6, #7, #8, #9, #10, #11, #14, #18

Column Parameters tab

**Bracing Conditions** Specify whether the columns are braced in the local y-y and/or z-z directions.

**Effective Length Factors** Specify the effective length factors to be used in the local y-y and z-z directions.

For either direction, whether it is braced (if not specify the stability index to use) and for sidesway whether a specific load case should be considered or the design load case should be used.

**Slenderness Limits** This may be set to 1, or calculated by the design.
Starter bars Specify the area of starter bar steel (in mm$^2$) to ensure that maximum area of steel is not exceeded by the design.

Other Parameters Select whether or not to include design for torsion.
Select whether or not to design as a Sway Frame
Specify the biaxial beta factor.
Specify the beta(d) value to use in the design.

Member Loadcases tab

Used to select load case results which are used for column design with this brief.

Available list Contains all primary load cases and load combinations in the STAAD.Pro input file.

Selected list Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

<table>
<thead>

<td>The maximum aggregate size used.</td>
</tr>
</tbody>
</table>
| **Lightweight**        | Select this option if a lightweight aggregate concrete is used. Specify either the average splitting tensile strength of the lightweight concrete value, Tensile fct, (if known) or the Lightweight Factor (by which √fc’ is multiplied, for when Tensile fct is not known) by selecting the appropriate option.  
  The Unit weight of the lightweight concrete must also be specified. |
| **Include Torsion Effects** | Select this option to consider torsion in the design of the reinforcement. |
| **Design moment at support** | Select whether the design section should be taken at the face or center-line of the support. |
| **Envelope**           | The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205). |
| **Divide Beam**        | Set the minimum number of segments that each member should be divided into for calculating the reinforcement (must be at least four). |
Top Bar Criteria

Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.
The Min gap defines the spacing between the top 2 layers.

**Bottom Bar Criteria**

Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing between the bottom 2 layers.

**Side Bar Criteria**

Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

**Main Bar**

Specify the steel strength and whether the steel is epoxy coated.

Select whether the development length is defined from cl 12.2.2 or cl 12.2.3.

Click the **Bending Dimensions**... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

**Note:** Bar sizes include: #3, #4, #5, #6, #7, #8, #9, #10, #11, #14, #18

Shear Reinforcement tab
Design Shear For

Select the option to design the shear reinforcement up to the Center Line of Column (support), Column Face (edge of support), or the distance 'd' from the Column Face. Note that the column or support face is defined in the Spans Table.
Select whether to **Include Axial Load Effects** in the longitudinal reinforcement.

**Shear Bar Criteria**

Specify the Bar Strength to use for shear reinforcement.

The bar size to use from the pull-down list of available sizes.

The minimum number of shear legs, 2, 3, 4, 5 or 6.

The minimum spacing between links to consider, if a smaller distance is required, then the number of legs will be increased.

Set whether the stirrups are defined as **Closed** or **Open** for the schedule.

Click the **Bending Dimensions**… button to open the Bending Dimensions dialog (on page 1157), which is used to specify the bending dimensions for each bar size.

**Note:** Bar sizes include: #3, #4, #5, #6, #7, #8, #9, #10, #11, #14, #18

**OK** Accepts parameters on all dialog tabs and closes the dialog.

**Cancel** Closes the dialog without saving any changes.

**Apply** Saves changes made in the dialog. Only available if changes have been made.

**Help** Opens the STAAD.Pro help window.

The ACI Column Design Brief has the following tabs for setting out the design parameters:

**Note:** Units used are dependant on the unit system (U.S. Customary or Metric) brief selected. Otherwise, the briefs are identical.

Materials tab
### Design

#### D. Concrete Design

**ACI 318-05 Column Design Brief**

- **Concrete**
  - Strength $f'_c$: 4 ksi
  - Aggregate size: 1.5 in
  - Cover: 2 in
  - Lightweight: Off
  - Tensile $f_t$: 0 ksi
  - Lightweight Factor: 0.75
  - Unit weight: 120 lb/cu ft

- **Main Bars**
  - Strength $f_y$: 60 ksi
  - Min Size: #6
  - Max Size: #11

- **Links**
  - Strength $f_y$: 60 ksi
  - Min Size: #4

**ACI 318M-05 Column Brief**

- **Concrete**
  - Strength $f'_c$: 28 MPa
  - Aggregate size: 40 mm
  - Cover: 50 mm
  - Lightweight: Off
  - Tensile $f_t$: 0 MPa
  - Lightweight Factor: 0.75
  - Unit weight: 1920 kg/cu m

- **Main Bars**
  - Strength $f_y$: 420 MPa
  - Min Size: #13
  - Max Size: #35

- **Links**
  - Strength $f_y$: 420 MPa
  - Min Size: #13

For Circular Sections Use:
- Tie Rft.
- Spiral Rft.
**Strength fc’**  The specified compressive strength of the concrete.

**Aggregate Size**  The maximum aggregate size used.

**Cover**  Specify the clear cover used outside the shear links.

**Lightweight**  Select this option if a lightweight aggregate concrete is used. Specify either the average splitting tensile strength of the lightweight concrete value, **Tensile fct** (if known) or the **Lightweight Factor** (by which $\sqrt{fc'}$ is multiplied, for when Tensile fct is not known) by selecting the appropriate option.

The Unit weight of the lightweight concrete must also be specified.

**Main Bars**  Specify the strength of the main bars, the range of sizes to consider from minimum to maximum sizes, and the bending dimensions.

Click the **Bending Dimensions…** button to open the [Bending Dimensions dialog](#) (on page 1157), which is used to specify bending dimensions for each bar size.

**Links**  Specify the strength of the tie or spiral bars (links), the minimum size link to consider, and the bending dimensions.

Click the **Bending Dimensions…** button to open the [Bending Dimensions dialog](#) (on page 1157), which is used to specify bending dimensions for each bar size.

For circular columns select whether the design should specify tie or spiral reinforcement.

**Note:** Bar sizes include: #3, #4,#5, #6, #7, #8, #9, #10, #11, #14, #18

Column Parameters tab
Effective Length Factors
Specify the effective length factors to be used in the local y-y and z-z directions.

Bracing Conditions
Specify whether the columns are braced in the local y-y and/or z-z directions or, if not, the Stability Index Q value for that direction.

Sidesway Load Case
Select whether a specific load case should be considered or the design load case should be used for causing sidesway.
Include Torsion Effects
Select this option to consider torsion in the design of the reinforcement.

Design as Sway Frame
Select this option if the frame(s) which include the column(s) are subject to sidesway.

Starter Bar Area Provided
Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

βd
Specify the sustained to total axial load value to use in the design as defined in Chapter 10 of ACI 318. This value is used to calculate the magnified moments for second order effects per section 10.11 and is dependent on the presence of sidesway.

Maximum spacing between main bars
Specify a maximum center-to-center spacing to be used for the longitudinal bars.

Member Loadcases tab
Used to select load case results which are used for column design with this brief.

| Available list | Contains all primary load cases and load combinations in the STAAD.Pro input file. |
| Selected list | Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group. |

**D. ACI 318-05 and 318M-05 Slab Design Brief** dialog
The ACI 318-05 Beam Design Brief has the following tabs for setting out the design parameters:

**Note:** Units used are dependant on the unit system (U.S. Customary or Metric) brief selected. Otherwise, the briefs are identical.

**General tab**
Design

D. Concrete Design

ACI Slab Design Brief

- **General**
  - Minimum Cover:
    - Top: 2 in
    - Bottom: 2 in
  - Concrete:
    - 4 ksi
    - Aggregate Size: 1.5 in
  - Envelope: E1: Envelope 1
  - Minimum distance between sample points: 20 cm

- **Main Reinforcement**

ACI 318M-05 Slab Brief

- **General**
  - Minimum Cover:
    - Top: 50 mm
    - Bottom: 50 mm
  - Concrete:
    - 28 MPa
    - Aggregate Size: 40 mm
  - Envelope: E1: Envelope 1
  - Minimum distance between sample points: 20 cm
**Minimum Cover**
These set the cover to the top and bottom of the slab.

**Concrete Grade**
Specify the compressive concrete strength of the concrete.

**Aggregate Size**
Specify the maximum size of aggregate.

**Envelope**
The slabs will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

**Note:** Top and bottom of slabs are defined by the local axis of the constituent elements.

It may or may not relate to the physical top or bottom of the slab. In order to eliminate any mismatch or confusion, please ensure that all local axes of constituent elements point in the positive y direction of the global coordinate axis.

This ensures consistency of element orientation and alignment of top and bottom of slabs with local axes.

Main Reinforcement tab
Design

There are two ways to carry out slab design. You may set fixed bar spacing and let the program calculate acceptable bar sizes to suit or fix the bar size and calculate acceptable bar spacing.

Main Bar Type

Specify the yield Strength of steel to be used for the main bars either from the available steel grades.

Top/Bottom Bar Criteria

Set the outer bar direction for top reinforcement to follow the ‘X’ or ‘Y’ axis of the slab. Set bar sizes for ‘X’ and ‘Y’ directions. Set bar spacing in the ‘X’ and ‘Y’ direction if design is based on fixed bar size.

**D. AIJ Member Briefs**

**D. AIJ Beam Brief** dialog
The AIJ Beam Design Brief has the following tabs for setting out the design parameters:

**General tab**

- **Minimum cover** Set the cover to the top, bottom and sides of the beams (in mm).
- **Aggregate Size** Specify the maximum size of aggregate to be used (in mm)
- **Concrete** Specify the concrete strength, Fc (in Kg/cm²).
  - Select whether this is a lightweight concrete mix.
- **Loading Type** Select whether the loading is Short Term or Long Term.
- **Envelope** The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the [Define Envelope dialog](on page 1205).
- **Divide Beam** Set the minimum number of segments that each member should be divided into for calculating the reinforcement.
Main Reinforcement tab

**Top Bar Criteria**
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

**Bottom Bar Criteria.**
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

**Main Bar Type.**
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.

The available steel grades include: SR235, SRR235, SR295, SRR295, SDR235, SD295A, SD295B, SDR295, SDR345, SD345 and SD390

Specify whether the bars are epoxy coated.

Select whether the 'Development Length' is taken from the ACI 318 code, clause 12.2.2 or 12.2.3

**Side Bar Criteria.**
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

Bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

**Note:** Unless stated otherwise the available bar sizes include: 8, 10, 13, 16, 19, 22, 25, 29, 32, 35, 38, 41

Shear Reinforcement tab
**Design Shear**

Select whether or not to include for the shear forces within the width of the column (or support) by selecting either 'center Line of Support' or 'Column face' (support) or at a distance 'd' from the face of the column (support).

**Shear Bar Criteria.**

Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

**Shear Bar Type.**

Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm$^2$) and set the bending dimensions to be used with that strength.

The available steel grades include: SR235, SRR235, SR295, SRR295, SDR235, SD295A, SD295B, SDR295, SDR345, SD345 and SD390

Specify whether the links are 'Open' or 'Closed' for the classifying in the schedule.

**Note:** Unless stated otherwise the available bar sizes include: 8, 10, 13, 16, 19, 22, 25, 29, 32, 35, 38, 41

D. AS 3600 Column Design Brief dialog

The AS 3600 Column Design Brief has the following tabs for setting out the design parameters:

General tab
Concrete Specify the concrete strength either from the available concrete grades or by defining a concrete strength, $f_{cu}$, (in N/mm$^2$).

Specify the minimum center to center spacing for reinforcement.

Specify the cover to the shear reinforcement.

Main Bars Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Links Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Column Factors tab
Bracing Conditions Specify whether the columns are braced in the local y-y and/or z-z directions.

Effective Length Factors Specify the effective length factors to be used in the local y-y and z-z directions.

Slenderness Limits This may be set to 1 (unity), or calculated by the design.

Area provided by starter bars Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

Member Loadcases tab

Used to select load case results which are used for column design with this brief.

Available list Contains all primary load cases and load combinations in the STAAD.Pro input file.
### Selected list
Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

### D. BAEL

**D. BAEL 91 Beam Design Brief** dialog
The BAEL Beam Design Brief has the following tabs for setting out the design parameters:

**General tab**
Minimum covers
Set the cover to the top, bottom and sides of the beams (in mm).

High Grip Bond Coefficient
Specify the value of $\psi_s$ (Psi s).

Aggregate Size
Specify the maximum size of aggregate used in the concrete mix (in mm).

Concrete Strength $f_{cj}$
Set the strength either from the list of available grades, or by defining the strength, $f_{cj}$ (in MPa).

Envelope
The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

Divide Beam
Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

Main Reinforcement tab
**Top Bar Criteria**  Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

**Bottom Bar Criteria**  Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

**Side Bar Criteria**  Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

**Main Bar Type**  Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.

The available steel grades include: Fe E 215, Fe E 235, Fe E 400 and Fe E 500

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Shear Reinforcement tab
Design

Shear For

Select whether or not to include for the shear forces within the width of the column (or support) by selecting either Center Line of Support or Column Face (support).

Select Include Axial Load Effects to account for the axial forces in design of longitudinal reinforcement.

Select whether 'k' in cl. A 5.1.23 should be taken as 0, 1 or calculated from the pull-down list.

Select the option Include Torsional Effects to consider torsion in the selection of reinforcement steel.

Shear Bar Criteria

Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Shear Bar Type

Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm²) and set the bending dimensions to be used with that strength.

The available steel grades include: Fe E 215, Fe E 235, Fe E 400 and Fe E 500

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

SLS Envelope tab
Envelope Select whether any defined envelope should be considered as the serviceability envelope.

Cracking Condition If an envelope is selected, then the cracking condition must be specified as either Detrimental or Very Detrimental.

Safety Factors tab

Concrete $\gamma_b$ Select whether the concrete safety factor, $\gamma_b$ (gamma b), should be taken as 1.5 or 1.0.
**Concrete** θ  Select whether the concrete factor, θ (theta), should be taken as 1.0, 0.9, or 0.85.

**Steel** γ_s  Select whether the steel safety factor, γ_s (gamma s), should be taken as 1.15 or 1.0.

**D. BAEL 91 Column Design Brief** dialog

The BAEL Column Design Brief has the following tabs for setting out the design parameters:

**General tab**

- **Concrete** Specify the concrete strength either from the available concrete grades or by defining a concrete strength, fcj, (in MPa).
  - Specify the maximum aggregate size.
  - Specify the cover to the shear reinforcement.
  - Available concrete grades include: 12, 16, 20, 25, 30, 40, 45 and 50

- **Main Bars** Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used (in MPa). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
  - Specify the minimum and maximum bar sizes to be used.
  - Available steel grades include: Fe E 215, Fe E 235, Fe E 400 and Fe E 500
Links

Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used (in MPa). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.

Available steel grades include: Fe E 215, Fe E 235, Fe E 400 and Fe E 500

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Column Factors tab

Slenderness

Specify the slope of the column e’ as length / (value).

Specify value for α (alpha).

Specify value for φ (phi).

Effective Length Factors

Specify the effective length factors to be used in the local y-y and z-z directions.

Starter bars

Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

Cracking Condition

Select whether cracking condition is either: Not Important, Detrimental, or Very Detrimental.

Safety Factors tab
Concrete $\gamma_b$ Select whether the concrete safety factor, $\gamma_b$ (gamma b), should be taken as 1.5 or 1.0.

Steel $\gamma_s$ Select whether the steel safety factor, $\gamma_s$ (gamma s), should be taken as 1.15 or 1.0.

Member Loadcases tab

Used to select load case results which are used for column design with this brief.

Available list Contains all primary load cases and load combinations in the STAAD.Pro input file.

**D. BS8110**

**D. BS 8110 Beam Design Brief** dialog
The BS8110 Beam Design Brief has the following tabs for setting out the design parameters:

**General tab**

<table>
<thead>
<tr>
<th>Minimum Cover</th>
<th>Aggregate Size</th>
<th>Concrete Strength Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top 30 mm</td>
<td>Max 20 mm</td>
<td>C40/50</td>
</tr>
<tr>
<td>Side 30 mm</td>
<td>User fcu 50.0 N/mm²</td>
<td></td>
</tr>
<tr>
<td>Bottom 30 mm</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Bond Coefficients**
- Tension: 0.5
- Compression: 0.64

**Envelope**
- Envelope 1
- Divide Beam into 12 Segments

**Minimum covers** Specify the cover to the top, bottom and sides of the beams (in mm).
**Bond Coefficients** Specify the values for use in calculating the anchorage lengths for both tension and compression.

**Aggregate size** Specify the maximum size of aggregate used in the concrete mix (in mm).

**Concrete Grade** Either select a standard grade from the pull-down list or enter the concrete cube strength into the user value (in N/mm$^2$). Available concrete grades include: C30, C35, C40, C45, and C50.

**Envelope** The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

**Divide Beam** Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

**Design for Torsion** Select this option to consider torsion in the design shear and longitudinal reinforcement.

### Main Reinforcement tab

![Main Reinforcement tab](image)

**Top Bar Criteria** Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

**Bottom Bar Criteria** Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

**Side Bar Criteria** Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

**Main Bar Type** Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.
The available steel grades include: T(460) and R(250)

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Shear Reinforcement tab

**Design**

**Shear For**
Select whether or not to include for the shear forces within the width of the column (or support) by selecting either **Center Line of Support** or **Column Face** (support).

Select **Use Enhanced Shear Effects** to increase shear capacity close to column (support) faces as the shear angle increase.

Select **Include Axial Load Effects** to account for the axial forces in design of longitudinal reinforcement.

**Shear Bar Criteria**
Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Select whether the links should be scheduled as **Closed** or **Open**.

**Shear Bar Type**
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm²) and set the bending dimensions to be used with that strength. The available steel grades include: R(250) or T(460)

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

*D. BS 8110 Column Design Brief* dialog
The BS8110 Column Design Brief has the following tabs for setting out the design parameters:

**General tab**

### Concrete
- Specify the concrete strength, $f_{cu}$, either selected as a standard grade or as a user specified value (in N/mm$^2$).
- Available concrete grades include: C30, C35, C40, C45 and C50
- Specify the maximum aggregate size used in the concrete mix (in mm)
- Specify the cover to the shear reinforcement (in mm)

### Main Bars
- Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used (in N/mm$^2$). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
- Specify the minimum and maximum bar sizes to be used.
- Available steel grades include: T(460) or R(250)

### Links
- Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used (in MPa). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
- Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.
- Available steel grades include: T(460) or R(250)
**Bracing Conditions**
Specify whether the columns are braced in the local y-y and/or z-z directions.

**Effective Length Factors**
Specify the effective length factors to be used in the local y-y and z-z directions.

**Slenderness Limits**
This may be set to 1, or calculated by the design.

**Area provided by starter bars**
Specify the area of starter bar steel (in mm$^2$) to ensure that maximum area of steel is not exceeded by the design.

**Member Loadcases tab**
Used to select load case results which are used for column design with this brief.
**Available list**  Contains all primary load cases and load combinations in the STAAD.Pro input file.

**Selected list**  Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

<table>

**D. BS8110 Slab Design Brief** dialog
The BS8110 Slab Design Brief has the following tabs for setting out the design parameters:

- General tab
**Minimum Cover**

These set the cover to the top and bottom of the slab.

**Aggregate Size**

Aggregate size sets the maximum size of aggregate.

**Concrete Grade**

Either select a standard grade from the pull-down list or enter the concrete cube strength into the user value.

Available concrete grades include: C30, C35, C40, C45 and C50

**Envelope**

The slabs will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

**Note:** Top and bottom of slabs are defined by the local axis of the constituent elements.

It may or may not relate to the physical top or bottom of the slab. In order to eliminate any mismatch or confusion, please ensure that all local axes of constituent elements point in the positive y direction of the global coordinate axis.

This ensures consistency of element orientation and alignment of top and bottom of slabs with local axes.

Main Reinforcement tab
Design

There are two ways to carry out slab design. You may set fixed bar spacing and let the program calculate acceptable bar sizes to suite or, fix the bar size and calculate acceptable bar spacing.

Wood and Armer

Select this option to use Wood & Armer moments.

Main Bar Type

Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used (in N/mm²). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Available steel grades include: T(460) or R(250)

Top/Bottom Bar Criteria.

Set the outer bar direction for top reinforcement to follow the ‘X’ or ‘Y’ axis of the slab.

Set bar sizes for ‘X’ and ‘Y’ directions.

Set bar spacing in the ‘X’ and ‘Y’ direction if design is based on fixed bar size.

D. CAN/CSA-A23.3-10 Briefs

D. CSA-A23.3-10 Beam Design Brief dialog

The CAN/CSA-A23.3-10 Beam Design Brief has the following tabs for setting out the design parameters:

General tab
Minimum Cover group
Set the cover to the Top, Side, and Bottom of the beams (in mm).

Concrete group
- **Strength f_c'**: Type the design strength of the concrete, f_c' (in MPa).
- **Aggregate Size**: Type the maximum size of aggregate used in the concrete mix (in mm).
- **Density**: Type the density of the concrete used (in kg/m³).
- **Interior / Exterior Exposure**: Select the exposure of the concrete based on its use in the structure.

Forces group
- **Include Torsion Effects**: Set this check box to consider torsion effects on the beam design.
- **At support, take design moment at**: Select where support moments should be considered: Center Line of Column or at Column Face.

Envelope
The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

Divide Beam into Segments
Set the minimum number of segments that each member should be divided into for calculating the reinforcement.
**Dead Load/Total Load Ratio**

Type the ratio of the dead load to total load to consider for service load.

**Main Reinforcement tab**

<table>
<thead>
<tr>
<th><strong>Top Bar Criteria</strong></th>
<th>Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bottom Bar Criteria</strong></td>
<td>Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.</td>
</tr>
<tr>
<td><strong>Other Bar Criteria</strong></td>
<td>Set either the Minimum Side Bar Size to be used along with minimum and maximum spacing to achieve a suitable spacing on deep beams.</td>
</tr>
</tbody>
</table>
| **Main Bar Group** | **Strength** Type the steel yield strength, \( f_y \), to use for the main reinforcing steel (in MPa).  
**Modulus** Type the modulus of elasticity for the reinforcing steel, \( E_s \) (in MPa).  
**Epoxy Coated** Set this check box when epoxy coated reinforcing steel is used for the main reinforcing. |

Click the **Bending Dimensions...** button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

**Shear Reinforcement tab**

*Note:* Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50
Shear Bar Criteria group

- **Bar Strength**: Type the steel yield strength, \( f_y \), to use for the shear reinforcing steel (in MPa).
- **Min Spacing**: Type a minimum spacing to use between shear bar (in mm).
- **Modulus**: Type the modulus of elasticity for the shear reinforcing steel, \( E_s \) (in MPa).
- **Bar Size**: Select the bar size to use for shear reinforcement.
- **Min No. of Legs**: Select the number of legs (2, 3, 4, 5, or 6) to be used.

Click the **Bending Dimensions...** button to open the **Bending Dimensions dialog** (on page 1157), which is used to specify bending dimensions for each bar size.

</tbody>
</table>

Include Torsion Effects  Set this option to consider torsion in the design of the reinforcement.

Design as Sway Frame  Set this option if the frames which include the columns are subject to sidesway.
**Design**

D. Concrete Design

---

**Ignore second order effects**

Select this option to ignore magnified moments accounting for second order effects.

**$\beta_d$**

Type the ratio of sustained axial load to total axial load to use in the design as defined in Chapter 10 and clause 10.14.1.3 of CAN/CSA A23.3-04. This value is used to calculate the EI value in equation 10-19.

** Started Bar Area Provided**

Type the area provided for initial main reinforcement steel (in mm$^2$).

**Max spacing between main bars**

Type the maximum spacing to be used between the longitudinal bars (in mm).

---

**Member Loadcases tab**

Used to select load case results which are used for column design with this brief.

---

**Available list**

Contains all primary load cases and load combinations in the STAAD.Pro input file.

**Selected list**

Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

D. CP65

D. CP65 Beam Design Brief dialog

The CP65 Beam Design Brief has the following tabs for setting out the design parameters:

General tab

Minimum covers Specify the cover to the top, bottom and sides of the beams (in mm).

Bond Coefficients Specify the values for use in calculating the anchorage lengths for both tension and compression.

Aggregate size Specify the maximum size of aggregate used in the concrete mix (in mm).

Concrete Grade Either select a standard grade from the pull-down list or enter the concrete cube strength into the user value (in N/mm²).

Envelope The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).
Divide Beam
Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

Main Reinforcement tab

Top Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

Bottom Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

Side Bar Criteria
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

Main Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.

The available steel grades include: T(460) and R(250)

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Shear Reinforcement tab
Design Shear For
Select whether or not to include for the shear forces within the width of the column (or support) by selecting either 'center Line of Support' or 'Column face' (support).

Select Use enhanced effects to increase shear capacity close to column (support) faces as the shear angle increase.

Select Include Axial Load Effects to account for the axial forces in design of longitudinal reinforcement.

Shear Bar Criteria
Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Shear Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm²) and set the bending dimensions to be used with that strength.

The available steel grades include: R(250) or T(460)

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Related Links

D. DIN1045

D. DIN 1045 Beam Design Brief dialog
The DIN 1045-1 Beam Design Brief has the following tabs for setting out the design parameters:

General tab
Top Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

Bottom Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

Side Bar Criteria
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

Envelope
The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

Divide Beam
Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

Materials tab
Main Bar Type

Either select a standard grade from the pull-down list or enter the steel yield strength, fyk (in N/mm²) into the user value and set the bending dimensions to be used with that strength as well as a factor to define ftk as a multiple of fy and the ultimate strain.

The available steel grades include: BSt 500 S(A), BSt 500 M(A), BSt 500 S(B) and BSt 500 M(B).

Concrete Grade

Either select a standard grade from the pull-down list or enter the concrete strength, fcu, into the user value (in N/mm²).

If a user strength is defined, then the maximum Elastic Strain and Ultimate Strain must also be defined.

Available concrete grades include: C12/15, C16/20, C20/25, C25/30, C30/37, C35/45, C40/50, C45/55, C50/60, C60/75, C70/85, C80/95, C90/105 and C100/115.

Aggregate Size

Specify the maximum size of aggregate used in the concrete mix (in mm).

Select whether the stress strain relationship should use the Idealised or Slant chart in Ref Bild 27.
Exposition Class

- Select option for **Reinforcement Corrosion, activated by carbonate influences**, either X0, XC1, XC2, XC3 or XC4.
- Select option for **Reinforcement Corrosion, activated by Chlorides, except sea water**, either **Not Applicable**, XD1, XD2 or XD3.
- Select option for **Reinforcement Corrosion, activated by sea water chlorides**, either **Not Applicable**, XS1, XS2 or XS3.
- Select option for **Attack risk by frost with or without de-icing chemicals** either **Not Applicable**, XF1, XF2 or XF3.
- Select option for **Attack risk by chemical attack by the environment** either **Not Applicable**, XA1, XA2 or XA3.
- Select option for **Concrete Attack by abrasion strain**, either 'Not Applicable, XM1, XM2 or XM3.
- Select option for **Fire Resistance Grade as per DIN 4102**, either **F30-B** or **F90-A**
- Specify **Reduction over C(min) for higher grade** (in mm)

The result of these selections will define the concrete cover, C(min), delta(c) and C(nom) and will suggest the minimum concrete grade that will be required for the design.

Shear Reinforcement tab
Design

D. Concrete Design

Design Shear

Select whether the design of shear force is taken to the face of the column (support) by selecting Use shear at support face or Use shear at a distance d from the support face to account for the enhanced shear effects close to the support.

Select option Design for torsion to account for the torsion forces in the beam.

Shear Bar Criteria

Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Shear Bar Type

Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm²) and set the bending dimensions to be used with that strength.

The available steel grades include: BSt 500 S(A), BSt 500 M(A), BSt 500 S(B) and BSt 500 M(B)

Note: Unless stated otherwise the available bar sizes include: 6, 8, 10, 12, 14, 16, 20, 25, 28, 32, 35 and 40

Arrangement tab
Specify **The overall depth of section limit for good anchorage bond** (in mm).

Specify **Minimum distance from top surface for good anchorage** (in mm).

Specify **Minimum anchorage length** (in mm)

Specify **Side cover limit relating to alpha(a) coefficient** (in number of diameters)

**Limit for spacing bars**

Set options to include minimum spacing of bars not less than **maximum bar diameter** and/or user dimension (in mm) on top of the limit of \(d(g) + 5\text{mm}\) when \(d(g) > 16\text{mm}\)
### Equation 127, Clause 11.2.2

- Specify **Value for k factor**
- Specify **Value for $f_{ct,eff}$** (in N/mm$^2$)
- Specify **sigma(s)** (as percentage of $f_{yk}$)

Specify **Allowable crack width limit for calculation of maximum allowable spacing** (in mm)

**Related Links**

**D. DIN 1045 Column Design Brief** dialog

The DIN1045-1 Column Design Brief has the following tabs for setting out the design parameters:

- General tab
**Concrete**  Specify the concrete strength, \( f_{ck} \), either selected as a standard grade or as a user specified value (in N/mm\(^2\)).

Available concrete grades include: C12/15, C16/20, C20/25, C25/30, C30/37, C35/45, C40/50, C45/55, C50/60, C60/75, C70/85, C80/95, C90/105 and C100/115

Specify the maximum aggregate size used in the concrete mix (in mm)

Specify the cover to the shear reinforcement (in mm)

**Main Bars**  Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used (in N/mm\(^2\)). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Available steel grades include: BSt 500 S(A), BSt 500 M(A), BSt 500 S(B) and BSt 500 M(B)

**Links**  Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used (in MPa). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 10, 12, 14, 16 or 20.

Available steel grades include: BSt 500 S(A), BSt 500 M(A), BSt 500 S(B) and BSt 500 M(B)

Unless stated otherwise, available bar sizes include: 12, 14, 16, 20, 25, 28, 32, 35 and 40

**Column Factors** tab

---

*STAAD.Pro*  1281  *User Manual*
Slenderness Limits
This may be set to 1, or calculated by the design.

Effective Length Factors
Specify the effective length factors to be used in the local y-y and z-z directions.

Starter bars
Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

Specify Maximum spacing between main bars (in mm)
Specify Minimum spacing between link bars (in mm)
Set whether to Use second order theory when slenderness < critical slenderness

User Settings - Main tab
Specify partial safety factors for concrete gamma(c) and steel gamma(s).

Specify sustained compression factors for rectangular and circular columns.

Specify **Minimum** and **Maximum** reinforcement percentages.

Specify **Minimum number of bars to be used in a circular column**.

Specify **Minimum transverse dimension of section** (in mm)

Specify **Upper slenderness limit for model column method**

**Limit for spacing**  Set options to include minimum spacing of bars not less than **maximum bar diameter** bars and/or user dimension (in mm) on top of the limit of $d_g + 5\text{mm}$ when $d_g > 16\text{mm}$

Boxed Values - Shear tab
Specify **Minimum diameter of links** (in mm) and **fraction of diameter of larges longitudinal bar**.

Select options to limit minimum spacing of links from the following:

- **A multiple of the longitudinal bar diameter**, specify the number for multiple.
- **Least dimension of the column**.
- **A minimum distance**, specify the distance (in mm).

**Clause 10.3.3 - Equation - 70**

Specify value of $\sigma_{cd}$.

Specify limit for value of $\rho_1$.

**Member Loadcases tab**

Used to select load case results which are used for column design with this brief.
Available list Contains all primary load cases and load combinations in the STAAD.Pro input file.

Selected list Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

<table>
<thead>

**D. Eurocode 2 2004 briefs**

D. Eurocode 2 2004 Beam Design Brief dialog

The EC2:2004 Beam Design Brief has the following tabs for setting out the design parameters:

- General tab
Minimum covers  Set the cover to the top, bottom and sides of the beams (in mm).
Aggregate Size  Specify the maximum size of aggregate used in the concrete mix (in mm).
Concrete Grade  Either select the strength either from the list of available grades in the pull-down list or by defining the strength, fck (in MPa).
Envelope  The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).
Divide Beam  Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

Main Reinforcement tab
Top Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams.
The Min gap defines the spacing (in mm) between the top 2 layers.

Bottom Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams.
The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.
The Min gap defines the spacing (in mm) between the bottom 2 layers.

Side Bar Criteria
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

Main Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.
Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.
Select the Class of the Main Bar from the pull-down list.

Shear Reinforcement tab
**Design Shear For**

Select whether or not to include for the shear forces within the width of the column (or support) by selecting either **Center Line of Support** or **Column Face** (support).

**Shear Bar Criteria**

Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Select if the links are to be detailed as **Closed** or **Open**.

**Shear Bar Type**

Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm$^2$) and set the bending dimensions to be used with that strength.

Click the **Bending Dimensions**... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

**National Annex tab**

Used to select a Eurocode 2 National Annex, if necessary, and open a dialog for editing National Annex parameters.
**Country**

Sets the country for which you want to use the National Annex. Select **EC2 without Annex** to use the EC2 code with no national annex changes or additions or to specify custom national annex values.

**Edit button**

Opens a dialog for editing national annex values. The dialog opened is dependant on the selected **Country** option.

- **UK National Annex** - Opens the dialog box (on page 1300), which is used editing EC2 values as directed by the UK National Annex.
- **EC2 without Annex** - Opens the dialog box (on page 1297), which is used to specify general National Annex values.

**D. EC2 2004 Column Design Brief**

The EC2:2004 Column Design Brief has the following tabs for setting out the design parameters:

Materials tab
Concrete

Specify the concrete strength either from the available concrete grades or by defining a concrete strength, fck, (in N/mm²).

Specify the minimum center to center spacing for reinforcement.

Specify the cover to the shear reinforcement.

Include Creep Effects

[BA] Creep effects can be accounted for in the design of compression members as specified in Cl. 5.8.6(3) & (4) of the code. The program requires the Effective Creep Ratio [Cl. 5.8.4(2)] as input to consider the creep effects.

Effective Creep Ratio

If creep is to be accounted for, specify an effective creep ratio to be used.

Main Bars

Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Links

Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.
Click the **Bending Dimensions**… button to open the **Bending Dimensions dialog** (on page 1157), which is used to specify bending dimensions for each bar size.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

### Column Factors tab

![Diagram of Column Factors tab](image)

- **Inclination**
  - Specify a value for $\theta$, for use in the structural analysis per clause 5.2(5).

- **Slenderness Criterion**
  - Select the slenderness criteria to be used for column design is per clause 5.8.3.1 or clause 5.8.3.3.

- **Ignore second order effects**
  - Select this option to ignore magnified moments accounting for second order effects.

- **Braced Conditions**
  - Specify whether the columns are braced in the local $y$-$y$ and/or $z$-$z$ directions.

- **Effective length factors**
  - Specify the effective length factors to be used in the local $y$-$y$ and $z$-$z$ directions.

- **Starter bar area provided**
  - Specify the area of starter bar steel (in mm^2) to ensure that maximum area of steel is not exceeded by the design.

- **Max spacing between main bars**
  - Specify the maximum spacing to be used between the longitudinal bars.

- **Min spacing between link bars**
  - Specify the minimum spacing to be used between link bars.

### National Annex tab

- Used to select a Eurocode 2 National Annex, if necessary, and open a dialog for editing National Annex parameters.
**Country**  
Sets the country for which you want to use the National Annex. Select **EC2 without Annex** to use the EC2 code with no national annex changes or additions or to specify custom national annex values.

**Edit button**  
Opens a dialog for editing national annex values. The dialog opened is dependant on the selected **Country** option.

- **UK National Annex** - Opens the [dialog box](on page 1300), which is used editing EC2 values as directed by the UK National Annex.
- **EC2 without Annex** - Opens the [dialog box](on page 1297), which is used to specify general National Annex values.

**Member Loadcases tab**  
Used to select load case results which are used for column design with this brief.
Available list Contains all primary load cases and load combinations in the STAAD.Pro input file.

Selected list Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

- *D. Eurocode 2:2004 Slab Design Principles* (on page 1049)

**D. EC2 2004 Slab Design Brief** dialog
The EC2 2004 Slab Design Brief has the following tabs for setting out the design parameters:

General tab
Minimum Cover
These set the cover to the top and bottom of the slab.

Aggregate Size
Aggregate size sets the maximum size of aggregate.

Concrete Grade
Either select a standard grade from the pull-down list or enter the concrete cube strength into the user value.
Available concrete grades include: C30, C35, C40, C45, and C50

Envelope
The slabs will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

Note: Top and bottom of slabs are defined by the local axis of the constituent elements.

It may or may not relate to the physical top or bottom of the slab. In order to eliminate any mismatch or confusion, please ensure that all local axes of constituent elements point in the positive y direction of the global coordinate axis.

This ensures consistency of element orientation and alignment of top and bottom of slabs with local axes.

Main Reinforcement tab
Design

There are two ways to carry out slab design. You may set fixed bar spacing and let the program calculate acceptable bar sizes to suite or, fix the bar size and calculate acceptable bar spacing.

Main Bar Type

Specify the strength of steel to be used for the main bars either from the available steel grades (S500 or S400) or by specifying the steel yield strength to be used (in N/mm$^2$). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Select the reinforcement Class as either A, B, or C. Reinforcement class is based on Table C.1 of EN 1992-1-1:2004.

Top/Bottom Bar Criteria

Set the outer bar direction for reinforcement to follow the ‘X’ or ‘Y’ axis of the slab.
Set the Bar Size for ‘X’ and ‘Y’ directions.
Set bar Spacing in the ‘X’ and ‘Y’ direction if design is based on fixed bar size.

National Annex tab

Used to select a Eurocode 2 National Annex, if necessary, and open a dialog for editing National Annex parameters.
Country

Sets the country for which you want to use the National Annex. Select **EC2 without Annex** to use the EC2 code with no national annex changes or additions or to specify custom national annex values.

Edit button

Opens a dialog for editing national annex values. The dialog opened is dependant on the selected **Country** option.

- UK National Annex - Opens the dialog box (on page 1300), which is used editing EC2 values as directed by the UK National Annex.
- EC2 without Annex - Opens the dialog box (on page 1297), which is used to specify general National Annex values.

Related Links

- *D. Eurocode 2:2004 Beam Design Principles* (on page 1044)
- *D. Eurocode 2:2004 Column Design Principles* (on page 1047)
- *D. Eurocode 2:2004 Slab Design Principles* (on page 1049)

D. National Annex Values dialog

Used to edit Eurocode 2 2004 concrete design parameters. This allows you to modify values for National Annexes not included in RC Designer by default.

Opens when the Edit button is selected in the **EC2-2004 Beam Design Brief** dialog box (on page 1286) National Annex tab, with the EC2 without annex option selected.

**Save as default values**

Sets the current values on the active dialog box tab as default values.

- **OK** Saves the current values and closes the dialog.
- **Cancel** Closes the dialog without saving any changes.
- **Apply** Saves any changes made in the dialog.
**Partial Factors for Materials 2.4.2.4 (1)**

Specify values to be used as $\text{Gamma } c (\gamma_c)$ and $\text{Gamma } s (\gamma_s)$.

**Design Compressive and Tensile Strengths 3.1.6**

*Alpha cc* is the coefficient to account for the long term effects on the compressive strength of concrete and any unfavorable effects due to the method of application of external loads.

*Alpha ct* is the coefficient to account for the long term effects on the tensile strength of concrete and any unfavorable effects due to the method of application of external loads.

**Slenderness Criterion 5.8.3.1 (1)**

Specify a ratio value (less than 1) which is to satisfy the "predominately" requirement in the note for this clause. This indicates the limit above which the end moments are considered to be caused "predominately" due to imperfections or transverse loads.
Detailing - Section 8 tab

Spacing of Bars 8.2 (2)
Specify values for k1 and k2 factors, which are used to set the minimum spacing requirements for reinforcing bars. The minimum clear bar spacing will be calculated as the maximum of:
- k1 x bar diameter, or
- K2 + maximum aggregate size, or
- 20 mm

Detailing - Section 9 tab

Minimum Tension Steel Area 9.2.1.1 (1)
Specify a coefficient to use in the calculation of $A_{s,\text{min}}$.
Similarly, specify a coefficient for $b_t d$ to take as the minimum value for $A_{s,\text{min}}$. 
### Solid Slab Maximum Bar Spacing 9.3.1.1 (3)
Specify a coefficient to use in the calculation of maximum spacing value to use in slabs (taken as a ratio of h).
Similarly, specify a maximum spacing value in mm.

### Minimum Compression Steel Area 9.5.2 (2)
Specify a coefficient to use in the calculation of $A_{s,\text{min}}$.
Similarly, specify a coefficient for $A_c$ to take as the minimum value for $A_{s,\text{min}}$.

### Maximum Longitudinal Reinforcement 9.5.2 (3)
Specify a coefficient to use in the calculation of $A_{s,\text{min}}$.
Similarly, specify a coefficient for $A_c$ to take as the minimum value for $A_{s,\text{min}}$.

---

#### Shear tab

**C Rd,c**  
Used to calculate the design shear resistance as per equation 6.2.a of the code.

**k1c**  
Used to calculate the design shear resistance as per equation 6.2.a of the code.

**Alpha cw**  
The coefficient to account for the state of the stress in the compression chord of the strut & tie mechanism used to calculate the design shear resistance of the member.

---

---

**D. UK National Annex Values** dialog
Used to control safety factors and other values specified in the UK National Annex to Eurocode 2: 2004.

Opens when the Edit button is selected in the *EC2-2004 Beam Design Brief* dialog box (on page 1286) National Annex tab, with the UK National Annex option selected.
Save as default values  Click to update the default values this dialog with the current values.

Partial Factors for Materials 2.4.2.4 (1) Specify values to be used as Gamma c (γ_c) and Gamma s (γ_s).

Slenderness Criterion 5.8.3.1 (1) Specify a ratio value (less than 1) which is to satisfy the "predominately" requirement in the note for this clause.

OK Saves the current values and closes the dialog.
Cancel Closes the dialog without saving any changes.
Apply Saves any changes made in the dialog.
Help Opens the STAAD.Pro Help window.

D. ECCS 203 Column Design Brief dialog

The ECCS 203 Column Design Brief has the following tabs for setting out the design parameters:

General tab
### Concrete Grade

Specify the concrete strength either from the available concrete grades or by defining a concrete strength, $f_{cu}$, (in N/mm$^2$).

- Specify the minimum center to center spacing for reinforcement.
- Specify the cover to the shear reinforcement.

Available concrete grades include: C20, C25, C30, C35, C40, C45 and C50

### Main Bars

Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

- Specify the minimum and maximum bar sizes to be used.

Available steel grades include: T(240), T280 and T(360).

### Links

Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

- Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.

Available steel grades include: T(240), T280 and T(360).

Unless stated otherwise, the range of available bars sizes includes: 12, 16, 20, 25, 32 and 40.

---

**Column Factors tab**
Bracing Conditions  Specify whether the columns are braced in the local y-y and/or z-z directions.

Effective Length Factors  Specify the effective length factors to be used in the local y-y and z-z directions.

Slenderness Limits  This may be set to 1, or calculated by the design.

Area provided by starter bars  Specify the area of starter bar steel (in mm$^2$) to ensure that maximum area of steel is not exceeded by the design.

Member Loadcases tab

Used to select load case results which are used for column design with this brief.

Available list  Contains all primary load cases and load combinations in the STAAD.Pro input file.
Selected list

Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

D. EHE

D. EHE Beam Brief
The EHE Beam Design Brief has the following tabs for setting out the design parameters:

General tab
Minimum cover  Set the cover to the top, bottom and sides of the beams (in mm).

Aggregate Size  Maximum size of aggregate to be used (in mm).

Concrete Grade  Set the strength either from the list of available grades, or by defining a cube strength, fck (in N/mm²).

Available concrete grades include: C25, C30, C35, C45 and C50

Envelope  The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

Divide Beam  Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

Main Reinforcement tab
Top Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

Bottom Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

Side Bar Criteria
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

Main Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.

The available steel grades include: B220S, B400S and B500S

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Shear Reinforcement tab
Design Shear For
Select whether or not to include for the shear forces within the width of the column (or support) by selecting either center Line of Support or Column face (support).

Select Include Axial Load Effects to account for the axial forces in design of longitudinal reinforcement.

Shear Bar Criteria
Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Shear Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm²) and set the bending dimensions to be used with that strength.

The available steel grades include: B220S, B400S and B500S

Boxed Values - General tab

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50
Specify the partial safety factors for concrete, \( \gamma_c \) and steel, \( \gamma_s \).

Specify the **Additional factor for sustained compression** \( \alpha \).

Specify the **Maximum percentage of tension and compression reinforcement**.

Select options for limiting spacing of bars to include:

- **Maximum bar diameter**
- **Specified dimension** (in mm).

Boxed Values - Anchorage & Slender tab

```
<table>
<thead>

</tbody>
</table>
```

Spacing of bars is not less than:

- \( d_b + 5 \text{ mm when } d_b > 32 \text{ mm} \)
- \( \checkmark \) maximum bar diameter,
- \( \checkmark \) 20 mm
Specify **Overall depth of section limit for good anchorage bond** (in mm)

Specify **Minimum distance from top surface for good anchorage** (in mm)

Specify **Minimum anchorage length** (in mm)

Specify **Side cover limit relating to \( \alpha_a \) coefficient** (as diameter)

Specify **Compression flange length factor limit for EC2 Eq. 4.77**

Specify Compression flange breadth factor limit for EC2 Eq. 4.77'

Boxed Values - Shear tab
Specify **Maximum \( \overline{d} \) of links** (max. diameter) (in mm).

Specify **Maximum longitudinal spacing of links when \( VSD \leq \frac{2}{3} VRd2 \)** (in mm).

Specify **Maximum longitudinal spacing of links when \( VSD > \frac{2}{3} VRd2 \)** (in mm).

Specify **Maximum transverse spacing of links** (in mm).

Specify **Upper limit of \( \beta \) used for shear enhancement**

Clause 44.2.3.2.1

Specify \( \sigma_{cp} \)

Specify ’Maximum value of \( \rho_1 \).

- *D. EHE Column Design Principles* (on page 1077)

D. EHE Column Design Brief dialog
The EHE Column Design Brief has the following tabs for setting out the design parameters:

General tab
Concrete

Specify the concrete strength either from the available concrete grades or by defining a concrete strength, fck, (in N/mm²).

Available concrete grades include: C25, C30, C35, C40, C45 and C50

Aggregate Size

Specify the maximum aggregate size.

Cover

Specify the cover to the shear reinforcement.

Main Bars

Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Available steel grades include: B220S, B400S and B500S.

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Links

Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.
**Slenderness Factors**  This may be set to 1, or calculated by the design.  Select value used in clause 43.5.2 from either 0.003 or 0.004'.

**Effective Length Factors**  Specify the effective length factors to be used in the local y-y and z-z directions.

**Starter bars**  Specify the area of starter bar steel (in mm$^2$) to ensure that maximum area of steel is not exceeded by the design.

**Spacing values**  Specify **Maximum allowable spacing between main bars** (in mm).  Specify **Minimum allowable spacing between link bars** (in mm).

---

**Boxed Values - Main tab**
Partial safety factors

Specify the partial safety factors for concrete, gamma(c) and steel, gamma(s).

Sustained compression factor

Specify Sustained compression factor for rectangular and circular columns.

Reinforcement Percentages

Specify Percentage of reinforcement limits for both Minimum and Maximum values.

Minimum no. of bars in a circular section

Specify Minimum number of bars to be used in a circular column.

Minimum transverse dimension of section

Specify Minimum transverse dimension of section (in mm).

Upper slenderness limit for model column method

Specify 'Upper slenderness limit for model column method.

Bar spacing options

Select options for limiting spacing of bars to include:

- Maximum bar diameter
- Specified dimension (in mm).

Boxed Values - Shear tab

Min. diameter of links

Specify Minimum diameter of link bars (in mm), and limiting fraction of diameter of longitudinal bars.

Link spacing options

Select option for minimum spacing of links do not exceed lesser of:

- Multiple of longitudinal bar diameters, specify the number of diameters.
- Least dimension of the column.
- Maximum distance, specify the distance (in mm).

Clause 44.2.3.2.1

Specify the values used in calculating the constant k, the average stress in the concrete due to axial force,
Specify the value of \( \sigma_{cp} \).
Specify the value \( \rho(1) \), maximum value of the reinforcement ratio corresponding to the area of reinforcement effective at the section under consideration.

Member Loadcases tab
Used to select load case results which are used for column design with this brief.

<table>
<thead>
<tr>
<th>Tool icon</th>
<th>Description</th>

Fax: (0411) 8479-7700
Concrete Design 混凝土构形手册

D. GB50010 Beam Design Brief dialog
The GB50010 Beam Design Brief dialog has the following tabs for setting out the design parameters:

Frame Information tab
Used to provide seismic lateral load resisting frame information for the portion of the structure containing the beam(s) associated with this brief.

Frame Type
Select the type of lateral load resisting system in which the beam(s) associated with this brief are used.
Beam Type

Beam element types, different types of reinforcement will affect the construction requirements.

Earthquake resistant Grade

Select the Grade classification for seismic design.

Select None if the component no seismic testing provisions are used for design (i.e., frame is not considered for seismic resistance).

Earthquake Intensity

Select the intensity level of the design earthquake.

Select None if no Earthquake is considered (i.e., frame is not considered for seismic resistance).

General tab

Minimum Cover
Set the cover to the top, bottom, and sides of the beams (in mm).

Concrete
Select a standard grade of concrete or select the User fcu option to specify a different strength value (in MPa).

Aggregate Size
The maximum aggregate size (in mm) used in the concrete mix.

Envelope
The beams will be designed to the forces from the envelope selected from the pull-down list.

Beam division
Set the minimum number of segments that each member should be divided into for calculating the reinforcement (must be at least four).

Main Reinforcement tab

Used to provided parameters for the longitudinal reinforcing bars.
### Top bar settings
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The Min gap defines the spacing (in mm) between the top 2 layers.

### Bottom bar settings
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links. The Min gap defines the spacing (in mm) between the bottom 2 layers.

### Side Bar Criteria
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

### Main Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the User fy field and set the bending dimensions to be used with that strength.

For User fy values, click the Bending Dimensions button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

---

**Shear Reinforcement tab**

Used to provide parameters for shear reinforcement (e.g., transverse stirrups).
Design Shear Reinforcement

Select the option to design the shear reinforcement up to the center line of the column (support) or column face (edge of support). Note that the column or support face is defined in the Spans Table.

Shear Bar Criteria

Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

Select whether the links should be scheduled as Closed or Open.

Shear Bar Type

Either select a standard grade from the pull-down list or enter the steel yield strength into the User fyv (in MPa) and set the bending dimensions to be used with that strength by clicking the Bending Dimensions... button (opens the Bending Dimensions dialog (on page 1157)).

- **OK** Accepts parameters on all dialog tabs and closes the dialog.
- **Cancel** Closes the dialog without saving any changes.
- **Apply** Saves changes made in the dialog. Only available if changes have been made.
- **Help** Opens the STAAD.Pro help window.

D. GB50010 Column Design Brief dialog
The GB50010 Column Design Brief dialog has the following tabs for setting out the design parameters:

Frame Information tab

Used to provide seismic lateral load resisting frame information for the portion of the structure containing the column(s) associated with this brief.

**Frame Type**
Select the type of lateral load resisting system in which the column(s) associated with this brief are used.

**Column Type**
Column element types, different types of reinforcement will affect the construction requirements.

- **Frame Col** General columns in a regular frame
- **Transfer Col** General columns in a transfer frame
- **Bot Frm** Columns at the base of a regular frame
- **Bot Trans** Columns at the base of a transfer frame
- **Top Trans** Columns at the top of a transfer frame
- **Corner** Corner Columns of a regular frame
- **Side** Side Columns of a regular frame
- **Middle** Internal Columns of a regular frame

**Earthquake resistant Grade**
Select the Grade classification for seismic design.
Design
D. Concrete Design

Select None if the component no seismic testing provisions are used for design (i.e., frame is not considered for seismic resistance).

**Earthquake Intensity**
Select the intensity level of the design earthquake.
Select None if no Earthquake is considered (i.e., frame is not considered for seismic resistance).

**General Settings tab**
Used to provide parameters for concrete strength, main reinforcement, and shear reinforcement in the columns.

![GB50010 Column Design Brief](image)

**Concrete**
the definition of concrete strength. Aggregate size can be ignored.

**Longitudinal bars, stirrups**
define the type and size of reinforcement.

**Concrete**
Select a standard grade of concrete or select the User fcu option to specify a different strength value (in MPa).

**Aggregate Size**
The maximum aggregate size (in mm) used in the concrete mix.

**Cover**
Set the cover used at the column faces (in mm).

**Main Bars**
Either select a standard grade from the pull-down list or enter the steel yield strength into the User fy field and set the bending dimensions to be used with that strength.

For User fy values, click the Bending Dimensions button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.
Set the Minimum and Maximum allowable bar sizes to be used.

**Links**

Either select a standard grade from the pull-down list or enter the steel yield strength into the **User fyv** (in MPa) and set the bending dimensions to be used with that strength by clicking the **Bending Dimensions...** button (opens the [Bending Dimensions dialog](#) on page 1157).

Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used.

Column Factors tab

Specify column conditions for bracing, effective length, and slenderness.

![GB50010 Column Design Brief](image)

- **Bracing Conditions**: Specify whether the columns are braced in the local y-y and/or z-z directions.
- **Effective Length Factors**: Specify the effective length factors to be used in the local y-y and z-z directions.
- **Slenderness Limits**: This may be set to 1, or calculated by the design.
- **Area provided by starter bars**: Specify the area of starter bar steel (in mm$^2$) to ensure that maximum area of steel is not exceeded by the design.

Member Loadcases tab

Used to select load case results which are used for column design with this brief.
**Available list**  Contains all primary load cases and load combinations in the STAAD.Pro input file.

**Selected list**  Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

**D. IS456**

**D. IS456 Beam Design Brief** dialog

The IS456 Beam Design Brief has the following tabs for setting out the design parameters:

- General tab
Minimum cover
Set the cover to the top, bottom and sides of the beams (in mm).

Minimum Reinforcement Spacing.
Specify the Minimum (in mm)

Beam Design option.
Select either 'Vertical Bending and Shear' or 'Lateral Bending and Shear'

Concrete Grade
Set the strength either from the list of available grades, or by defining a cube strength, fck (in N/mm²).

Available concrete grades include: M20, M25, M30, M35 and M40

Envelope
The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

Divide Beam
Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

Design for Torsion
Select whether the beam should include the design for torsion.

Check for IS 13920
Select this option to instruct the program to perform additional seismic checks per IS 13920 for the main bars.

Note: Select the Earthquake page (on page 1216) to check for collapse and shear criteria.

Main Reinforcement tab
### Top Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

### Bottom Bar Criteria
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

### Side Bar Criteria
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

### Main Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.

The available steel grades include: Fe250, Fe415 and Fe500

Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

### Shear Reinforcement tab

---

![Concrete Design Interface](image-url)
Design
Shear For
Select whether or not to include for the shear forces within the width of the column (or support) by selecting either 'Center Line of Support' or 'Column face' (support).
Select 'Enhanced Shear Effects' to account for changes in shear angle when approaching a column (support) face.
Select 'Include Axial Load Effects' to account for the axial forces in design of longitudinal reinforcement.

Shear Bar Criteria
Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.
Select if the links are to be detailed as Closed or Open.

Shear Bar Type
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value (in N/mm²) and set the bending dimensions to be used with that strength.
The available steel grades include: Fe250, Fe415, and Fe500.
Click the Bending Dimensions... button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40, and 50

The IS456 Column Design Brief has the following tabs for setting out the design parameters:
General tab

Concrete
Specify the concrete strength either from the available concrete grades or by defining a concrete strength, fck, (in N/mm²).
Specify the minimum center to center spacing for reinforcement.
Specify the cover to the shear reinforcement.
Available concrete grades include: M20, M25, M30, M35 and M40.

Main Bars
Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
Specify the minimum and maximum bar sizes to be used.
Available steel grades include: Fe250, Fe415 and Fe500.
Click the **Bending Dimensions…** button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Links
Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.
Available steel grades include: Fe250, Fe415 and Fe500.
Click the **Bending Dimensions…** button to open the Bending Dimensions dialog (on page 1157), which is used to specify bending dimensions for each bar size.

Check for IS 13920
Select this option to instruct the program to perform additional seismic checks per IS 13920 for the main bars.
Design
D. Concrete Design

**Note:** Select the [Earthquake page](#) (on page 1216) to check for collapse and shear criteria.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Column Parameters tab

**Bracing Conditions**
Specify whether the columns are braced in the local y-y and/or z-z directions.

**Effective Length Factors**
Specify the effective length factors to be used in the local y-y and z-z directions.

**Slenderness Limits**
This may be set to 1, or calculated by the design.

**Area provided by starter bars**
Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

Member Loadcases tab

Used to select load case results which are used for column design with this brief.
Available list  Contains all primary load cases and load combinations in the STAAD.Pro input file.

Selected list  Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

D. NS 3473 Column Design Brief dialog

The NS 3473 Column Design Brief has the following tabs for setting out the design parameters:

General tab
**Concrete**  Specify the concrete strength either from the available concrete grades or by defining a concrete strength, fck, (in N/mm²).

Specify the maximum aggregate size.

Specify the cover to the shear reinforcement.

Available concrete grades include: C25, C35, C45, C55, C65, C75 and C85

**Main Bars**  Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Available steel grades include: B400, B500 and B600.

**Links**  Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.

Available steel grades include: B400, B500 and B600.

Unless stated otherwise, the range of available bars sizes includes: 12, 16, 20, 25, 32 and 40.

Column Factors tab
Slenderness Factors  This may be set to 1, or calculated by the design.

Specify Creep coefficient

For long term loads, specify Longitudinal Force (in kN) and First order moment (in kNm)

Effective Length Factors  Specify the effective length factors to be used in the local y-y and z-z directions.

Area provided by starter bars  Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

Specify Maximum allowable spacing between main bars (in mm).

Specify Minimum allowable spacing between link bars' (in mm).

Boxed Values - Main tab
Specify **Partial safety factors** for Concrete, \( \gamma_c \) and Steel, \( \gamma_s \).

Specify **Sustained compression factor** for rectangular and circular sections.

Specify **Reinforcement percentages** both minimum and maximum values.

Specify **Minimum number of bars to be used in circular columns**

Specify **Minimum transverse dimension of section** (in mm)

Specify **Upper slenderness limit for model column method**

Specify **Minimum spacing of bars** on top of 2x bar limit.

Boxed Values - Shear tab

Specify **Minimum diameter of link** (in mm) and fraction of diameter of longitudinal bars.

</table>

Spacing of links does not exceed the lesser of:
- multiple of longitudinal bar diameter 12
- the least dimension of the column
- minimum distance 300 mm

Equation 4.18

\[
k = 1.50 - d + \frac{0.00}{\phi} - \frac{0.02}{1}
\]
Select whether options to limit spacing of links as:

- a user number diameters of longitudinal bar diameters.
- the least dimension of the column.
- a user dimension.

**Equation 4.18** Specify a value to use in k factor equation, with a lower limit

Specify \( \sigma_{cp} \)

Specify **Maximum value of \( \rho(1) \)**

**Member Loadcases tab**

Used to select load case results which are used for column design with this brief.

**Available list** Contains all primary load cases and load combinations in the STAAD.Pro input file.

**Selected list** Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

Note: The Russian Design Codes are only available with the ‘Euro-zone – Eastern Design Codes’ SELECT license.

General Tab

Concrete grade
Select a standard grade from the pull-down list.

Minimum Cover
Specify the cover to the top, bottom and sides of the beams (in mm).

Partial Safety Factors
Specify safety factors to be used in the design for both concrete and steel.

Design for (shear at)
Select whether or not to include for the shear forces within the width of the column (or support) by selecting either Center Line of Support or Column Face (support).
**Design for Torsion**  
Select this option to consider torsion in the design of the reinforcement.

**Envelope**  
The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the [Define Envelope dialog](#) (on page 1205).

**Divide Beam into**  
Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

**Reinforcement Tab**

![Reinforcement Tab](image)

**Main Bar Criteria**  
Select the Steel grade

Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams in the **Min Size** and **Max Size** fields, respectively. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The **Minimum gap between bars** defines the spacing (in mm) between the top 2 layers.

**Shear Bar Criteria**  
Select a standard grade from the pull-down list.

Select the minimum bar **Size** and **No. of Legs** to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

**Sag Bar Diameters**  
Select the criteria for selecting the sag bar diameters from either **Equal to hog bars**, **Optimized for each span independently**, or **Optimized for sag-critical span**.

**OK**  
Accepts parameters on all dialog tabs and closes the dialog.

**Cancel**  
Closes the dialog without saving any changes.

**Apply**  
Saves changes made in the dialog. Only available if changes have been made.

**Help**  
Opens the STAAD.Pro help window.

**Note:** The Russian Design Codes are only available with the 'Euro-zone – Eastern Design Codes' SELECT license.

General tab

- **Concrete**
  - Select a standard grade from the pull-down list. Specify the cover to the top, bottom and sides of the beams (in mm).

- **Effective Length Factors**
  - Specify the effective length factors to be used in the local y-y and z-z directions.

- **Partial Safety Factors**
  - Specify safety factors to be used in the design for both concrete and steel.

- **Equations for Circular Columns**
  - Select the methodology to be used for calculating the capacity of circular columns: Non-linear theory, SNiP 1984, or SNiP Alternative.
Main Bar Criteria

Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used (in MPa). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum and maximum bar sizes to be used.

Shear Bar Criteria

Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used (in MPa). If a user strength is defined, then the appropriate bar bending dimensions need to be specified.

Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.

Note: Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

Member Loadcases tab

Used to select load case results which are used for column design with this brief.
Available list  Contains all primary load cases and load combinations in the STAAD.Pro input file.

Selected list  Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

*D. TS500*
D. TS500 Beam Design Brief dialog

The TS500 Beam Design Brief has the following tabs for setting out the design parameters:

**General tab**

- **Minimum cover**
  - Set the cover to the top, bottom and sides of the beams (in mm).

- **Concrete**
  - Set the strength either from the list of available grades, or by defining a cube strength, fck (in N/mm²).
  
  Available concrete grades include: C20, C25, C30, C35, C40, C45 and C50

  Specify the maximum size of aggregate to be used (in mm)

- **Forces**
  - Select whether to design the forces within the width of the column (support) or only up-to the face of the column (support).

- **Envelope**
  - The beams will be designed to the forces from the envelope selected from the pull-down list. Load Envelopes are added using the Define Envelope dialog (on page 1205).

- **Divide Beam**
  - Set the minimum number of segments that each member should be divided into for calculating the reinforcement.

**Main Reinforcement tab**
**Top Bar Criteria**  
Set the Minimum and Maximum allowable bar sizes to be used on the top of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the top 2 layers.

Available bar sizes include: 12, 16, 20, 25, 32, 40 and 50

**Bottom Bar Criteria**  
Set the Minimum and Maximum allowable bar sizes to be used on the bottom of the beams. The link hanger size is used for detailing where no reinforcement bars are required for bending, but bars are required for supporting links.

The Min gap defines the spacing (in mm) between the bottom 2 layers.

Available bar sizes include: 12, 16, 20, 25, 32, 40 and 50

**Main Bar Type**  
Either select a standard grade from the pull-down list or enter the steel yield strength into the user value and set the bending dimensions to be used with that strength.

The available steel grades include: S220a, S420a or S500a

If the **User fyk** option is selected, specify a size. The bend radii can be specified in the Bending Dimensions dialog (on page 1157) by clicking the Bending Dimensions... button.

Select whether the ‘Development Length’ is taken from the ACI 318 code, clause 12.2.2 or 12.2.3

Select the **Epoxy Coated** option if the development length calculations should consider this reduction.

**Side Bar Criteria**  
Set either the minimum bar size to be used or let the program calculate which bars can be used to achieve a suitable spacing on deep beams.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50
Shear Reinforcement tab

**Design Shear Force**
Select whether or not to include for the shear forces within the width of the column (or support) by selecting either 'center Line of Support' or 'Column face' (support).

Select 'Include Axial Load Effects' to account for the axial forces in design of longitudinal reinforcement.

**Shear Bar Criteria**
Select the minimum bar size and number of legs (2, 3, 4, 5, or 6) to be used and set the minimum spacing (in mm). If the design requires a smaller spacing, then the number of legs will be increased.

**Shear Bar Type**
Select either a standard grade from the list or **User fyks** to specify the steel yield strength (in N/mm²). If the User fyks option is selected, you may also specify custom minimum bending radii to be used with that strength in the Bending Dimensions dialog (on page 1157) by clicking the Bending Dimensions... button.

The available steel grades include: S220a, S420a and S500a

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

**OK**
Accepts parameters on all dialog tabs and closes the dialog.

**Cancel**
Closes the dialog without saving any changes.

**Apply**
Saves changes made in the dialog. Only available if changes have been made.

**Help**
Opens the STAAD.Pro help window.

**Related Links**
- **D. TS 500 Beam Design Principles** (on page 1078)
- **D. TS 500 Column Design Principles** (on page 1080)
D. TS500 Column Design Brief dialog
The TS-500 Column Design Brief has the following tabs for setting out the design parameters:

General tab

Concrete
Specify the concrete strength either from the available concrete grades or by defining a concrete strength, fck, (in \( N/mm^2 \)).
Specify the maximum aggregate size, (in mm)
Specify the cover to the shear reinforcement, (in mm)
Available concrete grades include: C20, C25, C30, C35, C40, C45 and C50

Main Bars
Specify the strength of steel to be used for the main bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
Specify the minimum and maximum bar sizes to be used.
Available steel grades include: S220a, S420a and S500a.

Links
Specify the strength of steel to be used for the shear reinforcement bars either from the available steel grades or by specifying the steel yield strength to be used. If a user strength is defined, then the appropriate bar bending dimensions need to be specified.
Specify the minimum bar size to be used from 6, 8, 12, 16 or 20.
Select whether for circular columns either 'Tie' or 'Spiral' reinforcement should be used.
Available steel grades include: S220a, S420a and S500a
**Include Seismic Checks**
Select this option to include additional checks.

**Note:** Unless stated otherwise, the available bar sizes include: 6, 8, 10, 12, 16, 20, 25, 32, 40 and 50

**Column Factors tab**

- **Biaxial β factor**
  - Specify the value for the biaxial beta factor.

- **R_m**
  - Specify the value for the R(m) factor.

- **Include Torsion Effects**
  - Select this option to include torsion effects.

- **Design as Sway Frame**
  - Select this option to Design as Sway Frame.

- **Starter Bar Area Provided**
  - Specify the area of starter bar steel (in mm²) to ensure that maximum area of steel is not exceeded by the design.

**Slenderness Factors**
This may be set to 1, or calculated by the design.

Specify 'Creep coefficient'
For long term loads, specify 'Longitudinal Force' (in kN) and 'First order moment' (in kNm)

**Bracing Conditions**
in both local y-y and z-z directions.

Specify the effective length factors to be used.
Select whether or not the local axis is braced, and if not, the value of stability Index Q to use.
Select the load case to be used for Sidesway or use the same as the design load case.
Used to select load case results which are used for column design with this brief.

**Available list**  Contains all primary load cases and load combinations in the STAAD.Pro input file.

**Selected list**  Load cases and combinations the results of which will be used for the column design when this brief is used in a Design Group.

**D. Advanced Concrete Design**

This workflow launches the STAAD.Pro Advanced Concrete Design (RCDC) program, which is used for the design and detailing of reinforced concrete building structures.
The Advanced Concrete Design workflow provides direct access for STAAD.Pro models to leverage the power of the RCDC application. This is a standalone application, which is operated outside the STAAD.Pro environment, but requires a model and results data from a suitable analysis.

The model should typically be formed from beams and columns (plates are currently not supported). RCDC can be used to design the following objects:

- Pile Caps
- Footings
- Columns and walls (note walls are determined from a STAAD model as very wide columns, see the RCDC documentation for more details)
- Beams
- Slabs (zones defined by a loop of beams, not plates, see RCDC documentation for more details)

As projects progress, each design created in RCDC is retained and displayed when RCDC is reentered so that previous designs can be recalled and/or continued. If any analysis is performed on the STAAD.Pro model from when the RCDC document was last edited, this is identified as an old document and should be reviewed again to ensure that the results of the design are still valid.

**Note:** When using the model in STAAD.Pro Advanced, access to RCDC will be provided using the same STAAD.Pro Advanced license and no other license is required. If using STAAD.Pro (basic), then the Advanced Concrete Design workflow will still allow access to RCDC, but this will require the use of an additional license. This could either be a STAAD.Pro Advanced license or a STAAD Advanced Concrete license. Please check which licenses are available to you before attempting to use this and ensure that you use the correct license.

**D. Advanced Slab Design**

The STAAD.Pro Advanced Slab Design workflow is an integrated tool that works from within the STAAD.Pro environment. Concrete slabs can be defined and the data can be transferred to RAM Concept.

The data passed into RAM Concept includes the geometry, section and material properties, loads and combination information, and analysis results.

**Note:** This feature requires STAAD.Pro 2006 Build 1001 or higher and is compatible with RAM Concept version v2.1 and higher.

Basic reinforced concrete slab design per BS8110, ACI 318-05/ 318M-05, or EC2:2004 can also be performed using the **D. Interactive Concrete Design** (on page 1005).

**Note:** Beginning with STAAD.Pro CONNECT Edition, direct export to ADAPT-Builder® has been deprecated.

**D. Using the Advanced Slab Design workflow**

**Note:** A successful analysis of a STAAD.Pro input file is required before initiating and using the Advanced Slab Design workflow.

**D. To open the Advanced Slab Design workflow**

1. Open an input file (containing the slab to be designed) in STAAD.Pro.
2. Perform a successful analysis.
3. Select Advanced Slab Design in the Workflows panel.

D. To create a load envelope

1. Select the Envelopes page in the Advanced Slab Design page control bar.
The Envelopes table.

   **Tip:** This page is typically open by default.

2. Click New Envelope on the Envelopes table.
   workflow.
The Load Envelope dialog opens.

3. (Optional) Type a title for the load envelope.
   A Load Envelope name should be entered, being defined by the chosen load cases by clicking the check boxes corresponding to each load case.

4. Select the load cases or combinations to be included in the design load envelope.

   **Tip:** Check the Select All Load Cases Shown Below option to add all available load cases to the envelope.

5. For each load case included, select a Load Type to describe the nature of that load.
6. Click OK.
The new load envelope is added to the Envelopes table.

Related Links
- D. Envelopes table (on page 1356)
- D. Load Envelope dialog (on page 1356)

D. To create a slab definition

1. Select the Slab Design page in the Advanced Slab Design page control bar.
The Geometry Cursor tool is selected.

2. Select the structure geometry which will form the slab.

   **Note:** The slab geometry should include all plate elements which form the slab, as well as column members both above and below the slab, beam members framing the slab, and wall plate elements which are connected both above and below to the slab.

3. Click New Slab on the Slabs table.
The Slab Definition dialog opens.

4. Select the Load Envelope with which to associate the slab definition.
5. Click OK.
The new slab definition is added to the Slabs table.

   **Note:** If the selection of plates is such that the plates form two separated entities (e.g., plates that form parallel floors) then STAAD.Pro will create multiple separate slab entities.
D. To export slab definitions to RAM Concept

1. Select the slab design definition(s) in the Slabs table.
2. Select the Export > Export RAM Concept Information tool in the RAM Concept group on the Advanced Slab Design ribbon tab.

A dialog opens to confirm that the data files were created.

D. To open the STAAD.Pro slab data in RAM Concept

1. Select the slab design definition(s) in the Slabs table.
2. Either:
   Select the Export > Run RAM Concept tool in the RAM Concept group on the Advanced Slab Design ribbon tab.

   or

   Right-click on the Slabs table and select Run > RAM Concept from the pop-up menu.
   RAM Concept launches and The Concept import dialog opens.
3. Leave all structure geometry element types selected (default) and click OK.
   Upon the completion of a successful import, a message dialog opens to inform you of the total number of structural elements and loads created.

Refer to the RAM Concept documentation for assistance performing analysis and design operations.

D. Pages in the Advanced Slab Design workflow

The Pages in the Advanced Slab Design workflow are described below in brief.

Table 85: Page Controls in the Advanced Slab Design workflow

<table>
<thead>
<tr>
<th>Page</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Envelopes</td>
<td>Used to create set(s) from available Primary and Combination Loads defined in the current STAAD.Pro file for which analysis results are already available. When the Envelopes page is selected, the Envelopes table opens.</td>
</tr>
</tbody>
</table>
### Slab Design

<table>
<thead>
<tr>
<th>Page</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slab Design</td>
<td>Used to create Slab definitions for slab design. When the <strong>Slab Design</strong> page is selected, the <strong>Slabs</strong> table opens.</td>
</tr>
</tbody>
</table>

**D. Envelopes** table

Used to view a table containing all the load envelopes created by the user for the current model. This table will also open even if there is no load envelope created yet.

Opens when the **Envelopes** page is selected in the **Advanced Slab Design** workflow.

**Envelopes list**  Contains a list of all Envelopes available for Slab Design, along with the component load cases.

**New Envelope**  Opens the **Load Envelope** dialog (on page 1356), which is used to create a load envelope from defined loads.

**Edit Envelope**  Opens the **Load Envelope** dialog for editing the selected envelope.

**Related Links**

- **D. To create a load envelope** (on page 1354)

**D. Load Envelope** dialog

Used to define an envelope of primary and combined load cases used in the analysis that will then be used by RAM Concept for performing code checks or member selections.

Opens when **New Envelope** is clicked on the **Envelopes table** (on page 1356).
Envelope Name

Specify a title for the load envelope. The default title uses an incremented id number.

Select All Load Cases Shown Below

Select this option to add all load cases in the Defined Loads list to the new load envelope.

Defined Loads list

Lists all previously defined load cases in the input file. For each load selected for the Load Envelope, the Load Type must be defined.

The Load Type describes the nature of the load. Clicking in the cell for a Load Case opens a drop-down list containing all load types. Select the most appropriate type to make the assignment.

OK

Creates a new Load Envelope with the selected parameters and closes the dialog.

Cancel

Closes the dialog without creating a new load envelope.

Related Links

- D. To create a load envelope (on page 1354)

D. Slabs table

Contains the slabs already defined along with the associated design load envelope.

Opens when the Slab Design page is selected in the Advanced Slab Design workflow.
Slab no Lists sequential slab reference numbers (S1, S2, etc.)
Slab Name Name of the Slab definition.
Envelope name The load envelope associated with the slab.

New Slab Opens the Slab Definition dialog (on page 1358), which is used to create a slab definition from a set of selected plate elements.

Edit Slab Opens the Slab Definition dialog to edit or rename the currently selected slab.

Related Links
• D. To create a slab definition (on page 1354)

D. Slab Definition dialog

Used to create a slab definition from a set of selected geometry.

Opens when New Slab is clicked on the Slabs table (on page 1357).

Slab name (Edit mode only) Enter the name of the Slab definition. Slab definitions are automatically named with incrementing numbers when they are created.
Load Envelope Select a previously defined design load envelope from the list.
OK Closes the dialog and creates a slab from the selected geometry.
Cancel Closes the dialog without creating a slab definition.

Related Links
• D. To create a slab definition (on page 1354)
D. Foundation Design

The Foundation Design workflow integrates STAAD Foundation Advanced into STAAD.Pro. In this workflow, you can select loads and geometry to pass to a new STAAD Foundation Advanced project.

**Note:** This feature requires STAAD.Pro V8i (SELECTseries 2) (release 20.07.07) or higher.

**Tip:** Models containing a large number of supported nodes or load cases may result in slow performance on older computer hardware. Exporting a limited set of data can be used to improve performance in STAAD Foundation Advanced in these cases.

D. Using the Foundation Design workflow

**Note:** See Limited Versus Full Licensed Versions of STAAD Foundation Advanced (on page 1359) for details on the two license options available and the foundations that can be designed using those licenses.

Limited Versus Full Licensed Versions of STAAD Foundation Advanced

STAAD Foundation Advanced is available in two forms:

- licensed version
- a limited version which may be used with a STAAD Foundation Advanced license

**Note:** This limited version requires a license for STAAD.Pro but not a separate license for STAAD Foundation Advanced.

When you launch the program with STAAD Foundation Advanced installed, you are given a choices to select one of these in the **License Configuration** dialog. If you select the limited version option, then you only have access
to the items as indicated in the following table. If you have purchased a license then you will have access to all the modules in STAAD.Pro.

**Note:** All available design codes are included for each feature.

**Table 86: Items included in the free, limited version of STAAD Foundation Advanced**

Items indicated with a “✔” are available with a free, limited version license. Items indicated with an “X” require a license to use.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Feature Name</th>
<th>Limited Version (license free)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Toolkit</td>

<td>X</td>
</tr>
<tr>
<td>General</td>
<td>Combined with rib</td>
<td>X</td>
</tr>
<tr>
<td>Plant</td>
<td>All modules</td>
<td>X</td>
</tr>
</tbody>
</table>

**Tip:** If you uncheck the **Show on startup** option but need to access the **License Configuration** dialog, you can select the **License Configuration** tool in the **Settings** group on the **Home** ribbon tab.

D. To open the Foundation Design workflow

1. Perform a successful analysis.
2. Select **Foundation Design** in the **Workflows** panel.

The **Foundation Design** dialog opens.

D. To export all of the structure data to a STAAD Foundation Advanced project

This is the typical method of transferring data. Keep in mind that you can set up multiple jobs in STAAD Foundation Advanced, each containing some or all of the STAAD.Pro supports or load cases.
1. In the **Foundation Design Options** dialog, select the **All Supports** option if it is not already selected.
2. Click **Include All** to transfer all available load cases to the list of load cases to be included in design.
3. Click **STAAD Foundation Advanced**.
   STAAD Foundation Advanced opens and the STAAD.Pro support data and results are imported.

**D. To export a limited set of structure data to a STAAD Foundation Advanced project**

1. Either:
   - Use the **Node Cursor** tool (selected by default with then Foundation Design workflow is selected) to graphically select the support nodes you want to transfer. The **Selected Supports** option will be selected automatically in the **Foundation Design** dialog.
   - or
   - Select the **Listed Supports** option in the **Foundation Design** dialog and then type a list of node numbers.
2. Either:
   - Select one or more load cases in the **Excluded from design** list and click **Include** to transfer them to the **To be included in design** list.
   - or
   - Select the **Select Envelope** option and then select a load envelope from the drop-down list.
3. Click **STAAD Foundation Advanced**.
   STAAD Foundation Advanced opens and the STAAD.Pro support data and results are imported.

**Tip:** To change the loads or update the STAAD Foundation Advanced model per any geometry changes to your STAAD.Pro model, simply re-perform the steps involved in exporting the data.

**D. Foundation Design** dialog

Used to specify the supports and results to be exported to a STAAD Foundation Advanced project.

Opens when the **Foundation Design** workflow is selected.

<table>
<thead>

- *D. Batch Design versus Interactive Design Workflows* (on page 944)
D. To specify aluminum design code and parameters

To initiate the design of aluminum members and specify the code parameters, use the following procedure.

**Note:** To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the Analysis and Design ribbon tab, select Aluminium in the Design gallery.
   The Aluminum Design - Whole Structure dialog opens.
   **Note:** Only the US Aluminum code is available for design of aluminum members.
2. Click Define Parameters.
   The Design Parameters dialog opens.
3. Specify a value or option for each required parameter for a set of members and then click Add.
   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.
   **Note:** Different parameters can be used for different member type designs (e.g., columns, beams, etc.). Alternatively, you can use a separate set of parameters for different member types.
4. Click Close.
   The design parameters are marked with an icon. This indicates that the need to be assigned to members.
5. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

**Related Links**
- *D. Available Aluminum Design Codes* (on page 1362)
- *Aluminum Design - Whole Structure dialog* (on page 3086)

- *TR.48.1 Parameter Specifications* (on page 2851)

D. To specify aluminum design commands

To specify the code checking or design commands to be used for the aluminum design operation, use the following procedure.

1. On the Aluminum Design - Whole Structure dialog, click Commands.
   The Design Commands dialog opens.
2. To perform a design action, select one of the following options (as they are available for the code selection):
   **Select...**
   - check the capacity of the current member sizes
     the CHECK CODE tab
   - select a member size based on the last analysis results
     the SELECT tab
3. Click Add.
4. Click Close.
5. Assign the design commands to the appropriate members.
D. To generate aluminum take off

To generate a summary of all aluminum sections with their lengths and weights for the whole structure or a list of members, use the following procedure.

2. Select the TAKE OFF tab. This will generate a list of sections used including total length and weight.
3. Click Add.
4. Click Close.
5. Assign the take off command to members or to a named group of members.

D. Timber Design

D. Available Timber Design Codes

The following timber design codes are available in batch design in STAAD.Pro.

Table 89: Timber Design codes available in STAAD.Pro

<table>
<thead>
<tr>
<th>Country</th>
<th>Code</th>
<th>Title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Canada</td>
<td>CSA 086-01</td>
<td>Wood Design Standard</td>
</tr>
</tbody>
</table>
D. To specify timber design code and parameters

To initiate the design of timber members and specify the code parameters, use the following procedure.

**Note:** To reduce the number of load cases used in design operations, you may want to create a load envelope or load list prior to specifying the design.

Batch mode design is specified and performed in the Analytical Modeling workflow.

1. On the Analysis and Design ribbon tab, select Timber in the Design group gallery.
   The Timber Design - Whole Structure dialog opens.
2. In the Timber Design - Whole Structure dialog, select the applicable concrete design code from the Current Code drop-down list.
3. Click Define Parameters.
   The Design Parameters dialog opens.
4. Specify a value or option for each required parameter for a set of members and then click Add.
   You only need to specify parameters that require a different value from the default value. Repeat this step for all non-default parameters.

**Note:** Different parameters can be used for different member type designs (e.g., columns, beams, etc.). Alternatively, you can use a separate set of parameters for different member types.

5. Click Close.
   The design parameters are marked with an icon. This indicates that the need to be assigned to members.
6. Use one of the STAAD.Pro assignment methods to assign each parameter to the applicable members.

You will now need to instruct the program to perform a design command on these members.

**Related Links**

- D. Available Timber Design Codes (on page 1364)
- Timber Design - Whole Structure dialog (on page 3088)
- Design Parameters dialog (on page 3083)

D. To specify timber design commands

To specify the code checking or design commands to be used for the timber design operation, use the following procedure.

   The Design Commands dialog opens. The tabs (if any) available in this dialog are dependant on the current design code selection. Not all commands are available for every design code.
2. To perform a design action, select one of the following options (as they are available for the code selection):
To...

check the capacity of the current member sizes

select a member size based on the last analysis results

Select...

the CHECK CODE tab

the SELECT tab (AITC 1984 code only)

3. Click Add.
4. Click Close.
5. Assign the design commands to the appropriate members.

D. Design Codes

This section contains engineering reference material and input commands for structural design using batch mode. The codes are organized by country, material, and edition.

D1. American Codes

D1.A. American Codes - Steel Design per AISC 360 Unified Specification

Steel member design per ANSI/AISC 360-05, 360-10, and 360-16 Specifications for Structural Steel Buildings, is available in STAAD.Pro. These specifications are published as part of the AISC Steel Construction Manual. Since the ASD and the LRFD method are both addressed in those specifications, they are referred to as UNIFIED.

To use the 2016 edition (default), specify the command:

CODE AISC UNIFIED

or

CODE AISC UNIFIED 2016

To use the 2010 edition, specify the command:

CODE AISC UNIFIED 2010

To use the 2005 edition, specify the command:

CODE AISC UNIFIED 2005

Tip: Either method may be selected in the user interface using the Steel Design - Whole Structure dialog.

Design can be performed according to the provisions for Load and Resistance Factor Design (LRFD) or to the provisions for Allowable Strength Design (ASD), as per section B3 of the code. This selection of the design methodology can be done through the METHOD parameter. The full list of parameters is given in D1.A.6 Design Parameters (on page 1378).

Related Links
- G.17.2.1.4 AISC 360 Direct Analysis (on page 2352)
D1.A.1 General Comments on Design as per AISC Unified Code

Both Allowable Stress Design and Load Resistance Factor Design methods are implemented in STAAD. The selection of the method can be done through the METHOD parameter explained in the parameter list. This Unified Code allows the designer to design the member as per LRFD as well as ASD method.

**Design for Strength Using Load and Resistance Factor Design (LRFD)**

Design according to the provisions for Load and Resistance Factor Design (LRFD) satisfies the requirements of the AISC 360 Unified Code Specification, when the design strength of each structural component equals or exceeds the required strength determined on the basis of the LRFD load combinations.

Design shall be performed in accordance with Equation B3-1 of the Code:

\[ R_u \leq \varphi R_n \]

where

- \( R_u \) = required strength (LRFD)
- \( R_n \) = nominal strength
- \( \varphi \) = resistance factor
- \( \varphi R_n \) = design strength

**Design for Strength Using Allowable Strength Design (ASD)**

Design according to the provisions for Allowable Strength Design (ASD) satisfies the requirements of the AISC 360 Unified Code Specification when the allowable strength of each structural component equals or exceeds the required strength determined on the basis of the ASD load combinations.

Design shall be performed in accordance with Equation B3-2 of the Code:

\[ R_a \leq R_n / \Omega \]

where

- \( R_a \) = required strength (ASD)
- \( R_n \) = nominal strength
- \( \Omega \) = safety factor
- \( R_n / \Omega \) = allowable strength

D1.A.2 Section Classification

The LRFD specification allows inelastic deformation of section elements. Thus local buckling becomes an important criterion. Steel sections are classified as compact, non-compact or slender element sections depending upon their local buckling characteristics. This classification is a function of the geometric properties of the section. The design procedures are different depending on the section class. STAAD.Pro is capable of determining the section classification for the standard shapes and design accordingly.

The Section Classification is done as per section B4 and Table B4.1, for Stiffened and Un-Stiffened Elements of a section.

D1.A.3 Member Properties

For specification of member properties of standard American steel sections, the steel section library available in STAAD.Pro may be used. The syntax for specifying the names of built-in steel shapes is described in the next section.
D1.A.4 Built-in Steel Section Library

The following sections describe specification of steel sections from the AISC Steel Tables.

Related Links

• G.6.2 Built-In Steel Section Libraries (on page 2325)

D1.A.4.1 AISC Steel Table

Almost all AISC steel shapes are available for input. Following are the descriptions of all the types of sections available:

Wide Flanges (W shapes)

All wide flange sections as listed in AISC are available the way they are written, e.g., W10X49, W21X50, etc.

20 TO 30 TA ST W10X49
33 36 TA ST W18X86

C, MC, S, M, HP Shapes

The above shapes are available as listed in AISC (9th Edition) without decimal points. For example, C8X11.5 will be input as C8X11 and S15X42.9 will be input as S15X42, omitting the fractional portion of the weight past the decimal.

Note: Exception: MC6X151 for MC6X15.1 and MC6X153 for MC6X15.3.

10 TO 20 BY 2 TA ST C15X40
1 2 TA ST MC8X20

Double Channels

Back to back double channels, with or without spacing between them, are available. The letter D in front of the section name will specify a double channel.

21 22 24 TA D MC9X25
55 TO 60 TA D C8X18

Front to front channel steel sections can be defined by using the FR (Double Channel – Front to Front) option and any spacing required between the channels are specified with the SP designation.

61 62 TABLE FR C4X5 SP 0.5

Note: The SP parameter is optional, but if it is not set, the section will not be assumed to be a closed box for torsional calculations.

Angles

Angle specifications in STAAD.Pro are different from those in the AISC manual. The following example illustrates angle specifications.

\[ L_{40356} = L \times 3-1/2 \times 3/8 \]
Similarly, $L_{505010} = L 5 \times 5 \times 5/8$ and $L_{904016} = L 9 \times 4 \times 1$

At present, there are two ways to define the local y and z-axes for an angle section. To make the transition from the AISC Manual to the program data easy, the standard section for an angle is specified:

$51 \ 52 \ 53 \ TA \ ST \ L40356$

This specification has the local z-axis (i.e., the minor axis) corresponding to the Z-Z axis specified in the steel tables. Many engineers are familiar with a convention used by some other programs in which the local y-axis is the minor axis. STAAD provides for this convention by accepting the command:

$54 \ 55 \ 56 \ TA \ RA \ L40356$

**Note:** RA denotes reverse angle

**Double Angles**

Short leg back to back or long leg back to back double angles can be specified by inputting the word SD or LD, respectively, in front of the angle size. In case of an equal angle either LD or SD will serve the purpose.

$14 \ TO \ 20 \ TA \ LD \ L35304 \ SP \ 0.5$

Long leg back to back L3-1/2x3x1/4 with 0.5 space.

$23 \ 27 \ TA \ SD \ L904012$

Short leg back to back L 9x4x3/4

**Tees**

Tees are not input by their actual names, as they are listed in the AISC manual, but instead by designating the beam shapes (W and S) from which they are cut. For example

$1 \ 2 \ 5 \ 8 \ TA \ T \ W8X24$

Tee cut from W8x24, or a TW4x12.

**Pipes**

Two types of specifications can be used for pipe sections. Pipe sections listed in the AISC manual can be specified as follows.

$5 \ TO \ 10 \ TA \ ST \ PIPX20$

**PIPX20** = extra-strong pipe 2" in dia.

Pipe symbol - 10 times diameter in inches only portion before decimal

Strength spec -

Where the strength spec is one of the following:

- S = standard
- X = extra-strong
- D = double extra-strong

General pipe sections may be input by their outer and inner diameters. For example,

$1 \ TO \ 9 \ TA \ ST \ PIPE \ ØD \ 2.0 \ ID \ 1.875$

Indicates a pipe with an outer diameter of 2.0 and inner diameter of 1.875 in current input units.
Round HSS

Round hollow structural sections listed in the AISC manual can be specified as follows.

| 5 TO 10 | HSS16X0.438 |
| 11 TO 12 | HSS14X0.5_A1085 |

Indicates members 5 through 10 as 16” outer diameter and a nominal wall thickness of 7/16” (0.4375”). Members 11 and 12 have a 14” outer diameter and a 1/2” nominal wall thickness and use A1085 grade material.

**Notes:**

- AISC codes require that the design of HSS sections use section properties calculated based on a reduced wall thickness. The STAAD.Pro database values incorporated a design thickness of 0.93× the nominal thickness.
- HSS sections using A1085 grade material per the AISC 360-16 and 360-10 codes are designed using section properties with the full nominal wall thickness. Thus, a separate set of tables is available to specify this material grade as these use different section properties.

Tubes

Two types of specifications can be used for tube sections. Tube sections from the AISC tables can be specified as follows.

| 5 TO 10 | TA ST TUB120808 |

Indicates a tube that has a height of 8, a width of 6, and a wall thickness of 0.5 in the current input units.

**Note:** Member Selection cannot be performed on tubes specified by their dimensions. Only code checking can be performed on these sections.

Rectangular HSS

Rectangular hollow structural sections listed in the AISC manual can be specified as follows.

| 5 TO 10 | HSST14X10X0.313 |
| 11 TO 12 | HSST6X3X0.375_A1085 |

Indicates members 5 through 10 as a 14” x 10” tube with a nominal wall thickness of 5/16” (0.3125”). Members 11 and 12 are a 6” x 3” tube with a 3/8” nominal wall thickness and use A1085 grade material.
**D1.A.4.2 Welded Plate Girders**

The AISC welded plate girder shapes (pages 2-230 and 2-231 – AISC 9th edition) are available in the Steel Section library of the program.

<table>
<thead>
<tr>

- [D1.B.2 Castellated Beams](on page 1422)

**D1.A.5 Limit States**
D1.A.5.1 Axial Tension

The criteria governing the capacity of tension members are based on:

- Tensile Yielding in Gross Section and
- Tensile Rupture of Net Section.

The limit state of yielding in the gross section is intended to prevent excessive elongation of the member, and the corresponding check is done as per section D2-(a) of the code.

The second limit state involves fracture at the section with the minimum effective net area, and the corresponding check is done as per section D2-(b) of the code.

STAAD.Pro calculates the tension capacity of a given member based on these two limit states.

The Net Section Area may be specified by the user through the use of the parameter NSF (see D1.B.1.2 Design Parameters (on page 1409)). The Effective Net Area of tension members can be determined by using the Shear Lag Factor. You can also input the shear lag factor through the use of the parameter SLF.

D1.A.5.2 Axial Compression

The Design Compressive Strength (LRFD), $\phi_c \times P_n$, and the Allowable Compressive Strength (ASD), $P_n / \Omega_c$, are calculated by the program.

The Nominal Compressive Strength, $P_n$, shall be the minimum value obtained according to the Limit States of:

- Flexural Buckling,
- Torsional Buckling, and
- Flexural-Torsional Buckling.

The Nominal Compressive Strength, $P_n$, for a particular member is calculated by STAAD.Pro according to the procedure outlined in Chapter E, section E3 to E5, of the unified code specifications. For slender elements, the procedure described in section E7 is used.

Effective length for calculation of compression resistance may be provided through the use of the parameters KY and KZ. If not provided, the entire member length will be taken into consideration.

In addition to the compression resistance criterion, compression members are required to satisfy slenderness limitations which are a function of the nature of use of the member (main load resisting component, bracing member, etc.). In both the member selection and code checking process, STAAD.Pro immediately does a slenderness check on appropriate members before continuing with other procedures for determining the adequacy of a given member.

D1.A.5.3 Flexural Design Strength

The Design Flexural Strength (LRFD), $\phi_b \cdot M_n$, and the Allowable Flexural Strength (ASD), $M_n / \Omega_b$, are being calculated by the program.

The Nominal Flexural Strength, $M_n$, is determined according to Sections F2 through F12 of unified code specifications, for different types of rolled sections.

Doubly symmetric, I-shaped sections with slender flanges are also checked, as per Section F3 of AISC 360-10.

The Nominal Flexural Strength of a member is determined by the limit states of Yielding (Y), Lateral-Torsional Buckling (LTB), Flange Local Buckling (FLB), Web Local Buckling (WLB), Tension Flange Yielding (TFY), Leg Local Buckling (LLB), and Local Buckling (LB).
The program internally calculates the Lateral-Torsional Buckling Modification Factor \( C_b \) for non-uniform moment diagrams when both ends of the unsupported segment are braced. The purpose of this factor is to account for the influence of the moment gradient on lateral-torsional buckling.

To specify laterally unsupported length, the parameter UNF can be used, by default which takes the value of the member length.

**D1.A.5.4 Design for Shear**

The Design Shear Strength (LRFD), \( Q_v \times V_n \), and the Allowable Shear Strength (ASD), \( V_n / \Omega_v \), are calculated by the program, as per section G2 of the unified code specifications.

The Nominal Shear Strength, \( V_n \), of un-stiffened or stiffened webs, is calculated taking care of limit states of shear yielding and shear buckling. The sections G4 to G7 of the code specifications are used to evaluate Nominal Shear Strength, \( V_n \) for different types of rolled sections.

Shear Capacity Along the Major Axis

For determining shear capacity, \( V_c \) in the major axis Clause G2, G3, G4 are followed based on the different shapes.

**Note:** For user-defined sections the value of shear area will be used instead of the term ‘Aw’ in the equation in the above-mentioned clauses.

Shear Capacity Along the Weak Axis

The nominal shear strength, \( V_n \) for each shear resisting element in doubly symmetric and singly symmetric shapes loaded in the weak axis (minor axis, or along the flanges) without torsion in is determined per AISC 360-16 G6 as follows:

\[
V_n = 0.6F_y b_f t_f C_{v2} \tag{G6-1}
\]

The use of the section dimensions\[1\] \( b_f \& t_f \) in the above equation will be based on the section profile type. The following table lists the value of the terms \( b_f \), \( t_f \), \( k_v \), \( C_{v2} \) that are used in the calculation of shear capacities for various section profile shapes, when subject to shear along the z-axis of the section.

<table>
<thead>

</tr>
<tr>
<td>T - Section</td>
<td>( b_f = \text{Flange width} ) &amp; ( t_f = \text{flange thickness} )</td>
<td>( h = \text{Flange width} ) ( (b_f) ) &amp; ( t = \text{flange thickness} )</td>
<td>1.2</td>
</tr>
<tr>
<td>Solid bar / rod[3]</td>
<td>( B_f \times t_f = 0.5 \times \text{section area} )</td>
<td>1.0</td>
<td>-</td>
</tr>
</tbody>
</table>

### Notes:

1. For the shear in the weak axis, the value is determined using \( B_f \) and \( T_f \) alone. \( AZ \) cannot be used.
2. The shear capacities of the base I section and the top and/or bottom cover plates are evaluated separately using the dims shown and a \( k_v = 1.2 \). These values are then added to get the final section shear strength.
3. For solid rectangular bars and rods, half the total section area is assumed to resist the shear along the vertical axis and the other half to resist the shear along the horizontal axis. This could lead to conservative results in some cases.

- [V. AISC 360-16 Shear Weak Axis](on page 3881)

#### D1.A.5.5 Design for Combined Forces

The interaction of flexure and axial forces in singly and doubly symmetric shapes is governed by sections H1 and H3. These interaction formulas cover the general case of biaxial bending combined with axial force and torsion. They are also valid for uniaxial bending and axial force.

#### D1.A.5.6 Design for Torsion

Stresses due to torsion in non-HSS sections are considered per AISC 360-10 Section H3.3. This section states that the available torsional strength for non-HSS members shall be the least value obtained according to the limit states of yielding under normal stress, shear yielding under shear stress, or buckling:

\[
\phi_t = 0.9 \quad (LRFD), \quad \Omega_t = 1.67 \quad (ASD)
\]

For the limit state of yielding under normal stress (H3-7):

\[
F_n = F_y
\]

For the limit state of shear yielding under shear stress (H3-8):
The calculation of $F_v$ and $F_n$ is based on AISC Design Guide 9 *Torsional Analysis of Structural Steel Members* (DG-9). In general terms, in case of shear stress, $F_v$ will comprise of components of shear stress due to shear about both axes, warping shear stress and shear stress due to pure torsion. In case of normal stress $F_n$, stress due to axial force and stress due to flexure about both axes is considered. For some sections, like Single Angles and Tees, the component due to warping is negligible with respect to stress for pure torsion (Ref. Section 4.2 and 4.3 of Design Guide 9).

**Notes**

- STAAD.Pro will perform these torsion design checks when the **TORSION** parameter has been set to 1 (these are *not* checked by default).
- When torsion checks are performed, TRACK 3 output may be used to provide detailed torsion design output for Design Guide 9 checks.
- The torsion checks per Design Guide 9 require additional analysis to calculate $\Theta$ (rotation of the element due to applied torsion; refer to the following sections) at the 13 design segments along the member. Thus there is a performance cost for each torsion check. Therefore, it is recommended that torsion checks only be performed on the necessary members (rather than all members).

**Pure Torsional Shear Stress**

These shear stresses are always present in the cross-section of a member subjected to torsional moment. They are in plane shear stresses which vary linearly along the thickness of an element.

\[ \tau_t = G t \Theta' \]

where

- $\tau_t$ = the pure torsional shear stress at the element edge
- $G$ = the shear modulus of elasticity of steel
- $t$ = thickness of the element
- $\Theta'$ = first derivative of rotation expressed as a function of local $x$ (distance from start end to point where rotation is calculated)

In the case of an element with a rectangular cross section:

\[ \tau_t = T_u t/J \]

In the case of a hollow circular element or a pipe section with an inner radius of $R$:

\[ \tau_t = T_u R/J \]

In the case of a tube section:

\[ \tau_t = T_u/(2bht) \]

where

- $T_u$ = the total torsional moment action at any location along the beam

**Shear Stress Due to Warping**

When warping in a member is restrained, in plane shear stresses are developed which are constant along thickness of the element but vary along the length of the element.

\[ \tau_{ws} = -E S_{ws} \Theta''/t \]

where

\[ F_v = 0.6 F_y \]
where
\[ \tau_{ws} = \text{shear stress at a point, } s, \text{ due to warping} \]
\[ E = \text{the modulus of elasticity of steel} \]
\[ t = \text{thickness of the element} \]
\[ S_{ws} = \text{warping statical moment at a point, } s \]
\[ \Theta''' = \text{third derivative of rotation expressed as a function of local } x \text{ (distance from start end to point where rotation is calculated)} \]

**Note:** The shear stress due to warping is neglected for angle, tee, tube, or pipe sections.

Normal Stress Due to Warping

When warping in a member is restrained, direct stress acting perpendicular to the cross-section of the element is generated. These stresses are constant along the cross-section but vary along the length of the member.

\[ \sigma_{ns} = EW_{ns}\Theta'' \]

where
\[ \sigma_{ns} = \text{normal stress at a point, } s, \text{ due to warping} \]
\[ E = \text{the modulus of elasticity of steel} \]
\[ W_{ns} = \text{normalized warping function at a point, } s \]
\[ \Theta'' = \text{second derivative of rotation expressed as a function of local } x \text{ (distance from start end to point where rotation is calculated)} \]

**Note:** Point s refers to a point on the cross section area of a particular section as explained in Section 3.2.2 of Design Guide 9.

Combined Stresses due to Axial, Bending, and Torsional Stresses

Under section 4.6 of Design Guide 9, the combined stress in a section due all the stresses as explained in sections 4.1, 4.2, 4.3, and 4.4 is

\[ f_n = \sigma_a + \sigma_{bz} + \sigma_{by} + \sigma_s \]
\[ f_t = \tau_{sz} + \tau_{sy} + \tau_t + \tau_{ws} \]

These stresses are calculated at 13 sections along the beam length.

Considered Loads

Only member loads of the following types are considered in these checks:

- concentrated torque (moment about local x axis)
- concentrated force eccentric from the member shear center
- uniformly distributed torque (full or partial)
- uniformly distributed force eccentric to the member shear center
- end torques (only considered when end supports are fixed)

Linearly varying torque is *not* considered in the torsion checks. Joint loads are also *not* considered in the torsion checks.

The boundary conditions for torsional analysis and the method to calculate rotation, \( \Theta \), and its derivatives are used as described in DG-9.

STAAD.Pro calculates the stresses due to flexure, pure torsion, and warping torsion at 13 different sections along the member length. The total stress is the vector summation at each location.
D1.A.5.7 Design of Web-Tapered Members

AISC 360 05/10 specifications have been incorporated into STAAD.Pro to perform code checking on web tapered wide flange, square, and round shapes.

**Note:** Member selection cannot be performed on web-tapered members. That is, SELECT ALL, SELECT OPTIMIZE, and PROFILE are not applicable to web-tapered members.

The section properties used for web-tapered members are based on interpolated values between the start and depths of the member. Similar interpolation of values from start and end values is done for square and round tapered members.

**Related Links**

- **TR.20.3 Tapered Member Specification** (on page 2468)

D1.A.5.8 Design of I-Section with Cover Plates

STAAD.Pro can design I-sections with cover plates per AISC 360-05 and AISC 360-10.

According to B4.2(c) (p.16.1-15) of the AISC 360-05 specification, the cover plate is taken as a stiffened element and the width of a flange plate in a built-up section is taken between as the distance between lines of fasteners or welds. For the compression flange, the appropriate classification in Table B4.1 is that of case 12, which explicitly includes “flange cover plates and diaphragm plates between lines of fasteners or welds.” The section classification limits for this case are:

\[
\lambda = \frac{b}{t}
\]

\[
\lambda_p = 1.12 \sqrt{\frac{E}{F_y}}
\]

\[
\lambda_r = 1.40 \sqrt{\frac{E}{F_y}}
\]

where

- \( b \) = width of the cover plate
- \( t \) = thickness of the cover plate

Similarly, according to B4.2(c) of the AISC 360-10 specification, the cover plate is taken as a stiffened element and the width of the flange plate in a built-up section is taken as the distance between lines of fasteners or welds. For the compression flange, case 7 is used.

\[
\lambda = \frac{b}{t}
\]

\[
\lambda_r = 1.40 \sqrt{\frac{E}{F_y}}
\]

For flexure, case 18 is used.

\[
\lambda = \frac{b}{t}
\]
\[ \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} \]

\[ \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} \]

The section classification is included in the STAAD.Pro output listed as UNSTIFFENED / STIFFENED elements of the shape, along with the classification limits calculated as above and the element slenderness ratio, \( \lambda \).

In addition to the limit states described elsewhere in this section, I-sections with cover plates have the following considerations for code checking per AISC 360-05/10:

- For Section E4, the program determines if the section is doubly or singly symmetric. Based on this, E.4-4 or E.4-5 is used for the compression code check, respectively. An I-section with the same cover plate top and bottom remains doubly symmetric. An I-section with differing top and bottom plates or only a top or a bottom cover plate is singly symmetric.

- For lateral-torsional buckling calculations, the values of \( r_t \) and \( a w \) are calculated as described in F4.2 for the effective radius of gyration in section ii.

- For shear, the minimum of all b/t ratios - including the flanges and top and bottom cover plates - is used for the web slenderness in the horizontal direction.

- For shear, the cover plates are checked for tension field action.

- The cover plates are considered in the seismic classification of the section.

It is assumed that the section classifications are for I-section flanges, web, and cover plates but not for parts of elements (i.e., outstanding flange).

**Note:** The following two items are not checked for I-sections with cover plates:

- The effects of the cover plates for flange local buckling of the section. Only the I-section flanges are considered in the FLB calculation.
- AISC Design Guide 9 is not incorporated.

**D1.A.6 Design Parameters**

Design per AISC 360-05, 360-10, and 360-016 (Unified) specifications is requested by using the CODE parameter. Other applicable parameters are summarized in the following Table. These parameters communicate design decisions from the engineer to the program and thus allow you to control the design process.

The default parameter values have been selected such that they are frequently used numbers for conventional design. Depending on the particular design requirements, some or all of these parameter values may be changed to exactly model the physical structure.

### Parameter Name | Default Value | Description
--- | --- | ---
TBRC | (AISC 360-16 only) | Type of torsional bracing:
- 0 = None
- 1 = continuous bracing
- 2 = point bracing
- 3 = special bracing

Used to calculate bracing requirements as per seismic provisions in AISC 341-16.

TFA | (AISC 360-16 only) | 0
Tension field action to be considered in shear design:
- 0 = do not consider
- 1 = consider

TMAIN | 300 | Allowable slenderness limit for tension members.

TND | (AISC 360-16 only) | 1
Torsion loading and end condition as in Table in Appendix C.4 of AISC Design Guide 9:
- 1 = Equal concentrated end torques. Both ends free.
- 2 = Equal concentrated end torques. Both ends fixed.
- 3 = Concentrated Torque. Both ends pinned.
- 4 = Uniformly distributed torque. Both ends pinned.
- 6 = Concentrated Torque. Both ends fixed.
- 7 = Uniformly distributed torque. Both ends fixed.
- 9 = Concentrated Torque. One end fixed, another end free.
- 10 = Partial uniformly distributed torque. One end fixed, another end free.
- 12 = Uniformly distributed torque. One end fixed, another end pinned.

The number corresponds to the case number of the case chart in Appendix B of DG9. Set TORSION 1 to enable Torsion check as per DG9.

TORSION | (AISC 360-10 and 360-16 only) | 0
Specifies design for torsion per AISC Design Guide 9. See D1A.5.6 Design for Torsion (on page 1374)
- 0 = Do not perform torsion checks
- 1 = Perform torsion checks

**Note:** When torsion checks are performed, TRACK 3 output may be used to provide detailed torsion design output for Design Guide 9 checks.

| UNB            | Member Length | Unsupported length of the bottom flange for calculating flexural strength. Will be used only if compression is in the bottom flange. See Note 3 below. |
| UNL            | Member Length | Unsupported length of left extreme flange for LTB that will be used as lateral-torsional buckling length for the section with the vertical axis as major principal axis and where the left extreme fiber is in compression. If member is assigned with any value of UNL and FLX=2 concurrently, LTB length of the member will be treated as zero. |
| UNR            | Member Length | Unsupported length of right extreme flange for LTB that will be used as lateral-torsional buckling length for the section with the vertical axis as major principal axis and where the right extreme fiber is in compression. If member is assigned with any value of UNR and FLX=2 concurrently, LTB length of the member will be treated as zero. |
| UNT            | Member Length | Unsupported length of the top flange for calculating flexural strength. Will be used only if compression is in the top flange. See Note 3 below. |
| WTYP (AISC 360-05 and 360-10 only) | 0 | Weld type for HSS per Sect. B3.12 (AISC 360-05) or Sect. B4.12 (AISC 360-10):  
|                |               | 0 = Electric resistance welding  
|                |               | 1 = Submerged arc welding  
|                |               | For HSS Rectangle and Round profiles from AISC databases, the weld type will always be determined based on profile table (grade A1085 or not). WTYP will have no effect on these. For any other hollow profiles (pipe, tube, box, etc.) from AISC databases, all hollow profiles from any other country databases, and User Provided tables, the weld type must be specified using the WTYP parameter. |

**Notes**

1. For the AISC 360 unified code, an angle is automatically checked for geometric axis bending (in addition to principal axis bending) provided one of the following conditions is met:
   
   i. The FLX parameter is set to 2 for that member. The section could be an equal or an unequal legged angle.
ii. The angle is equal-legged, has bending moment only about one of its geometric axes, and is not subjected to axial compression.

The AXIS parameter is only used by the deprecated AISC 360-05 code checking method (CODE AISC UNIFIED OLD). If this code is used, then AXIS 1 specifies design based on principle axes, where AXIS 2 specifies design based on geometric axes.

2. Non-default values of CB must be re-entered before every subsequent CHECK CODE or SELECT command.

3. Top and Bottom represent the positive and negative side of the local Y axis (local Z axis if SET Z UP is used).

4. For a description of the deflection check parameters DFF, DJ1, DJ2 see the Notes section of D1.B.1.2 Design Parameters (on page 1409) of this manual.

5. NSF is the Net Section Factor as used in most of the steel design codes in STAAD.Pro. It is defined as the Ratio of “Net cross section area” / “Gross section area” for tension member design. The default value is 1.0. For the AISC 360 code, it is described in section D3.2.

6. SLF is the Shear Lag Factor, as used in Section D.3.3 of the AISC 360-05 code. This factor is used to determine the effective net area by multiplying this factor with net area of the cross section. Please refer to Table D3.1 of the 360 code for a list of acceptable SLF values. In STAAD.Pro, the default value for SLF is 1.0. The effective net area is used to determine the tensile strength for tensile rupture in the net section, as per equation D.2.2.

7. To summarize, the “Gross Area” (Ag) is multiplied by NSF to get the “Net Area” (An) of the section. The “Net Area” (An) is again multiplied by SLF to get the “Effective Net Area” (Ae) of the section.

8. For the design of a single angle for flexure, the parameter LX should be used to specify the value of the term “L” in equations F10-4a, F10-4b, F10-5 and F10-6 of AISC 360-05 and the term “Lb” in equations F10-4, F10-5, F10-6a, and F10-6b of AISC 360-10.

9. When BEAM is 1.0 (default), the design is performed at 13 evenly spaced points along the length of the beam, including start and end points (i.e., 1/12th points or at ends of 12 equal length segments).

![Figure 141: The default sections for design when BEAM 1.0 is used](image)

When BEAM is 0.0, the start and ends along with up to three locations specified in TR.41 Section Specification (on page 2839) are designed.

D1.A.7 Code Checking and Member Selection

Code Checking and Member Selection options are both available in the AISC 360 Unified Code implementation in STAAD.Pro.

For additional information on code checking, refer to:

- D1.B.1.3 Code Checking (on page 1418) for general information and
- TR.49 Code Checking Specification (on page 2852) for input command details

For additional information on member selection refer to:

- D1.B.1.4 Member Selection (on page 1419) for general information and
D1.A.8 Tabulated Results of Steel Design

Results of Code Checking and Member Selection are presented in the output file. The output is clearly marked for the selected specification (AISC 360), edition used (2010 or 2005), and the design method (LRFD or ASD).

The following details are presented on Code Checking of any member:

- Result of Code Checking (Pass / Fail) for the member Number.
- Critical Condition which governed the design and the corresponding Ratio and Location.
- Loads corresponding to the Critical Condition at the Critical Location.
- Section Classification
- Slenderness check report
- Section Capacities in Axial Tension, Axial Compression, Bending, and Shear in both the directions.

If Seismic provisions are to be checked, these follow as described in D1.A.9 Seismic Provision Checking per AISC 341 (on page 1388)

Note: An asterisk following a critical load case number indicates that this load case is a generated load combination. See TR.35 Load Combination Specification (on page 2791) for additional information.

D1.A.9 Seismic Provision Checking per AISC 341

Additional parameters may be specified for member checking or design per AISC 360-05, 360-10, or 360-16 to perform seismic provision checks per the corresponding edition of AISC 341.

The SEISMIC parameter is used to specify seismic provision checks for members. For those members in the AISC 360-05 or 360-10 editions, the MTYP (member type), FRM (frame type), and BRC (bracing type) parameters are used to specify the structure and member details. For the AISC 360-16 edition, only the MTYP (member type) parameter is used to specify the member details. See D1.A.6 Design Parameters (on page 1378) for details on the values used for these parameters.

Provisions Checked

The following checks are performed with the SEISMIC 1 parameter for the AISC 341-05/10 specifications:

- seismic classification of the member - the “worst case” classification is considered among all elements for the member. For
  - For members in an ordinary moment frame (OMF) or intermediate moment frame (IMF), the general section classification of AISC 360-05/10 is used.
  - For members in a special moment frame (SMF), the classification per table I-8-1 of AISC 341-05 or table D1.1 of AISC 341-10, respectively, are used.
- required flexural strength of the member -
  - OMF - $M_r = M_z$ (moment about major axis), per Sec. 11.8 of AISC 341-05 or Sec. E.1.4 of AISC 341-10
  - IMF - $M_r = M_u = R_yZF_y$ (LRFD) or $= R_yZF_y/1.5$ (ASD) per Sec. 10.8 of AISC 341-05 or Sec. D.1.2a of AISC 341-10
  - SMF - $M_r = M_u = R_yZF_y$ (LRFD) or $= R_yZF_y/1.5$ (ASD) per Sec. 9.8 of AISC 341-05 or Sec. D.1.2b of AISC 341-10
- required bracing strength
• Relative bracing for beams - $P_{br} = 0.008M_rC_d/h_0$ per eq. A-6-5 of AISC 360 05/10
• Nodal bracing for beams - $P_{br} = 0.02M_rC_d/h_0$ per eq. A-6-7 of AISC 360 05/10
• Relative bracing for columns - $P_{br} = 0.004P_r$ per eq. A-6-1 of AISC 360 05/10
• Nodal bracing for columns - $P_{br} = 0.01P_r$ per eq. A-6-3 of AISC 360 05/10
• required bracing stiffness: each of the following are multiplied by $1/\phi$ for LRFD or by $\Omega$ for ASD:
  - Relative bracing for beams - $\beta_{br} = 4M_rC_d/(L_b h_0)$ per eq. A-6-6 of AISC 360 05/10
  - Nodal bracing for beams - $\beta_{br} = 10M_rC_d/(L_b h_0)$ per eq. A-6-8 of AISC 360 05/10
  - Relative bracing for columns - $\beta_{br} = 2P_r/L_b$ per eq. A-6-2 of AISC 360 05/10
  - Nodal bracing for columns - $\beta_{br} = 8P_r/L_b$ per eq. A-6-4 of AISC 360 05/10

• required bracing spacing
  - OMF - no requirement
  - IMF - $L_b = 0.17r_yE/F_y$ per Sec 10.8 of AISC 341-05 or Sec. D.1.2a of AISC 341-10
  - SMF - $L_b = 0.086r_yE/F_y$ per Sec 9.8 of AISC 341-05 or Sec. D.1.2b of AISC 341-10

Provisions Checked for AISC 341-16

The following checks are performed with the SEISMIC 1 parameter for the AISC 341-16 specification:

• Section seismic classification against ductility – the section is evaluated to be seismically compact or seismically non-compact for either highly or moderately ductile members (specified using the DUCT parameter)
• Required flexural strength of member checked per D1-1
• Stability bracings of beam
  - Maximum allowed spacing of bracings checked per D1-2
  - Required strength of lateral beam bracing at panel type flange lateral bracing (A-6-5 of AISC 360-16), point type flange lateral bracing (A-6-7 of AISC 360-16), and special flange lateral bracing at plastic hinge locations (D1-4)
  - Required strength of torsional beam bracing at point torsional bracing (A-6-9 of AISC 360-16), continuous torsional bracing, and special torsional bracing at plastic hinge locations (D1-5)
  - Required stiffness of beam bracing at panel type flange lateral bracing and point type flange lateral bracing (A-6-6 of AISC 360-16)
  - Required stiffness of torsional bracing at point torsional bracing (A-6-10 and A-6-11 of AISC 360-16) and continuous torsional bracing (A-6-13 of AISC 360-16)
• Special bracing at plastic hinge locations (D1-6)
• Stability bracings of column
  - Required strength of column bracing at panel type bracing (A-6-1 of AISC 360-16) and point lateral bracing (A-6-3 of AISC 360-16)
• Stability bracing of beam-column
  - Required strength of lateral beam bracing at panel type flange lateral bracing and point type flange lateral bracing (A-6-4 of AISC 360-16)
  - Combination of lateral and torsional bracing
Output

The output for the AISC 341-05/10/16 checks follow the checks for AISC 360-05/10/16 for a member. No seismic provision checks are printed for TRACK 0 output. For TRACK 1 output, the seismic classification and the requirements are given. TRACK 2 adds the details of the classification limits.

D1.A.10 AISC 360-16 Design

The checking or selection of members is performed per the following sections of AISC 360-16 and AISC 341-16:

- Section Classification: Chapter B
- Tension Chapter D
- Compression: Chapter E
- Flexure: Chapter F
- Shear: Chapter G
- Torsion (Including checks as per DG-9 for certain profile shapes – see below): Chapter H & Design Guide 9 for Torsion design
- Combined actions – Chapter H for:
  - Axial and/or
  - Flexure and/or
  - Shear and/or
  - Torsion
- Checks for Seismic suitability – AISC 341-16

The following section profile shapes are allowed for design:

- Rolled Shapes
  - I-Shape
  - Channel
  - Single angle
  - Solid Circular bar
  - Solid Rectangular bar
  - Tee
  - HSS rectangular
  - HSS round
- Built Up Shapes
  - Built Up Channel
  - Built Up I
  - Double Channels – back to back
  - Double Channels – face to face
  - Double Angles
  - Built Up Box
  - I With Cover Plates (Top and/or bottom)
- Tapered Shapes
  - I with web tapered
  - Square hollow shape with wall tapered
  - Circular hollow shape diameter tapered
Note: Certain checks (e.g., DG-9 torsion checks) will only be performed for certain profile shapes (non-HSS shapes).

Seismic Design per AISC 341-16
Refer to Provisions Checked for AISC 341-16 (on page 1389) for additional details.

D1.A.10.1 Tension
Design of the members subject to axial tension is performed per chapter D of AISC 360-16.
All the cross-section profiles described in section 1A.10 are considered for tension checks.
Eye bars and pin-connected members are not checked per clauses D5 and D6.

Limit States
The tensile strength is calculated with due consideration to both tensile yielding and tensile rupture effects as per D.2 of the code.
The \( F_y \) and \( F_u \) values would be chosen based on the grade of steel associated with the member, specified by SGR parameter. Note that the implementation also provides a means to create custom steel grades. If SGR is set to 0 ("custom steel"), then the values assigned for FYLD and FU is used respectively.

Slenderness Limits
The code does not mandate the maximum slenderness limit for members in tension. However, the program will check against a maximum slenderness ratio (L/r) which is specified using TMAIN parameter. The length considered to calculate the tension slenderness will be the full member length.

Effective Net Area
The gross area, \( A_g \), and net area, \( A_n \), of tension members shall be determined in accordance with the provisions of Section B4.3 of AISC 360-16.
The effective net area is the net area multiplied by the parameter SLF (shear lag factor).
The net area is the gross area multiplied by the parameter NSF (net section factor).

D1.A.10.2 Compression
Design of the members subject to compression is performed per chapter E of AISC 360-16.
All the cross-section profiles described in section 1A.10 are considered for compression.
The design compressive strength is calculated based on the applicable limit states of flexural buckling, torsional buckling, and flexural-torsional buckling modes as per CLE.1.
The nominal compressive strength, \( P_n \), shall be the lowest value obtained based on the applicable limit states of flexural buckling, torsional buckling, and flexural-torsional buckling. In general, Table.E1.1 is followed for the choice of applicable sections/clauses for the various cross section shapes.

Limit States
Following limit states are checked for flexure per Equations E3-1, E3-2, and E3-3 for without slender elements:
- Flexural buckling about X axis
- Flexural buckling about Y axis
- Flexural buckling about U axis (for unsymmetrical shapes only)
• Flexural buckling about V axis (for unsymmetrical shapes only)
• Flexural-torsional buckling

Flexural-torsional buckling is checked per Equations E4-1, E4-2, and E4-3, E4-4, E4-7. Note the following:
• Check no performed for solid rect or circ bars, thin-walled rect or circ hollow sections, double-channel face-
to-face (only when channels are connected by full weld or tension bolts), or single angles with compact long legs.

The gross area is used for members with non-slender elements whereas the effective area, \( A_n \), is used for slender elements. The effective width of a slender element of any section other than round HSS is calculated for each limit state of compression as per eq. E7-2 or eq. E7-3 depending on the condition mentioned in the specification. The effective area \( (A_n) \) for a slender HSS round section is calculated as per cl. E7.2.

Parameters

The design parameters that affect compression are:
• LEG
• LZ
• LY
• LX
• KZ
• KY
• KZ
• SNU
• CSP

Slenderness Limits

The code does not mandate the maximum slenderness limit for members in compression. However, the program will check against a maximum slenderness ratio \((L/r)\) which is specified using MAIN parameter whose default value is 180. The length considered to calculate the compression slenderness will be the full member length.

**D1.A.10.3 Flexure**

Design strength in flexure is calculated as per clause F1. The

Limit States

The nominal flexural strength is calculated for different limit states as per sections F2 through F13.

The following limit states are checked for flexure:
• Flexural Yielding about X and Y axis
• Flexural Yielding about U and V axis (for single angle only)
• Lateral-torsional Buckling about X and Y axis
• Lateral-torsional Buckling about U axis (for single angle only)
• Flange Local Buckling
• Web Local Buckling
• Wall Local Buckling (for HSS Round only)
• Compression Flange Yielding
• Tension Flange Yielding

Parameters
The design parameters that affect flexure are:

- UNT
- UNB
- UNL
- UNR
- FLX
- SNU
- CB

**D1.A.10.4 Shear**

Design of the members subject to shear is performed per chapter G of AISC 360-16. All the cross-section profiles described in section 1A.10 are considered for shear. An option to consider tension field action is available. Also, the option to consider the shear capacity of I sections or channel shapes with transverse web stiffeners.

The program does not consider any specific checks for web openings in clause G7.

The design of transverse web stiffeners is not performed.

**Limit States**

The design shear strength is calculated per G1.

The nominal shear strength is calculated for the following sections:

- I-Shapes and Channels G2
- Single Angles and Tees G3
- Rect HSS, Box Sections, and other Doubly Symmetric Members G4
- Round HSS G5
- Shear capacity along weak axis in Doubly Symmetric and Singly Symmetric Shapes G6

**D1.A.10.5 Combined Forces and Torsion**

The effects of combined actions of axial force with major and minor axis moments are accounted for the following:

Doubly and Singly symmetric members subject to flexure and compression - H1.1

- Rolled I
- Rolled Channel
- Solid circular bar
- Solid rectangular bar
- Tee
- HSS Rectangle
- HSS Round
- Built Up Channel
- Built Up I
- Double Channels – back to back
- Double Angles
- Built Up Box
• I Profile With Cover Plates (Top and/or bottom)

Doubly and Singly symmetric members subject to flexure and tension - H1.2

• Rolled I
• Rolled Channel
• Solid circular bar
• Solid rectangular bar
• Tee
• HSS Rectangle
• HSS Round
• Built Up Channel
• Built Up I
• Double Channels – back to back
• Double Angles
• Built Up Box
• I Profile With Cover Plates (Top and/or bottom)

Doubly symmetric rolled compact members subject to single axis flexure and compression – H1.3

If you prefer to use only cl. H1.1 even when cl. H1.3 is applicable, this may be done with the INT parameter.

Unsymmetrical and other members subject to Flexure and Axial Force - H2

This section is used to check single angles.

Members Subject to Torsion and combined Torsion, Flexure, Shear, and Axial Force - H3

Checks for members subject to pure torsion or subject to torsion combined with other effects such as flexure or axial loads will be performed based on the profile shape of the member. Only the following section profiles are considered when performing torsion checks:

• Closed profiles
  • HSS Rectangle
  • HSS Round
  • Solid Circular bar
  • Solid Rectangular bar

• Open profiles
  • Rolled I
  • Rolled Channel
  • Tee
  • Single angle
  • Built-up I
  • Built-up Channel (Only if symmetric about X-X)
  • I Profile With Cover Plates (Top and/or bottom)

The implementation will perform the AISC 360-16 code checks as per clauses H.3.1 and H.3.2 for circular & rectangular hollow shapes. For all other shapes listed above, the component will follow the design methods as per AISC Design Guide -9: Torsional Analysis of Structural Steel Members (DG-9).
For non-HSS members subject to torsion and combined stress, the program cannot detect the load-end restraint condition automatically from the model. You can specify this through TND parameter. Also, for some cases the distance where the torque is applied must be provided through the ALH parameter.

RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10
- RR 21.03.00-3.1 Static Seismic Loads per IBC 2015 / ASCE 7-10 (on page 94)

**D1.A.10.6 Updates to AISC 360-16**

This section highlights the changes implemented from AISC 360-16 from AISC 360-10.

Section Classification

The width to thickness ratio limits for members in flexure have been updated for the following element types as per AISC 360-16:

- Stems of tees (14) are considered slender when \( \frac{d}{t} > 1.52 \frac{E}{F_y} \).
- Flanges of box sections (21) are considered slender when \( \frac{b}{t} > 1.49 \frac{E}{F_y} \).

**CHAPTER E Compression Checks: Torsional & Flexural-Torsional Buckling Calculations**

Design for the following profile shapes/conditions have been updated to use the corresponding clauses/equations from AISC 360-16:

2.a Cl. E4: Non-Slender Double Angles & Tee Shapes
- Calculation of \( F_{ez} \) and \( F_{ey} \) to use (E4-9) and (E4-8).
- Calculation of \( F_{e} \) to use (E4-3).
- Calculation of \( F_{cr} \) to use (E3-2) or (E3-3).
- Calculation of \( P_{n} \) to use (E4-1).

2.b Cl. E5: Single-Angle Compression Members
- Flexural torsional buckling limit for single angles changed to \( \frac{b}{t} \leq 0.71 \frac{E}{F_y} \).

2.c Cl. E7: Compression Members with Slender Elements
- Calculation of nominal compressive strength and critical stress \( F_{cr} \) updated to follow the updated criteria from Clause E7.

**CHAPTER F Flexure Checks**

Design for flexural members has been updated to use the following:

3.a Cl.F4 : Non-Standard[other] I Shaped Members

Lateral Torsional Buckling:
The calculation of effective radius of gyration, \( r_t \), updated to use the AISC 360-16 equation F4-11 for I-shapes with a rectangular compression flange:

\[
r_t = \frac{b_f c}{\sqrt{12(1 + \frac{1}{6a_w})}} \quad \text{(F4-11)}
\]

3.b Cl.A : Tension Flange Yielding
The tension flange yielding checks have been updated to use the updated web plastification factor calculations as per equations F4-16a to F4-17.

1. When \( \frac{I_{yc}}{I_y} > 0.23 \)
   
   i. When \( \frac{h_c}{t_w} \leq \lambda_{pw} \)
   
   \[ R_{pt} = \frac{M_p}{M_{yt}} \]  
   
   \[(F4-16a)\]

   ii. When \( \frac{h_c}{t_w} > \lambda_{pw} \)
   
   \[ R_{pt} = \left( \frac{M_p}{M_{yt}} - \left( \frac{M_p}{M_{yt}} - 1 \right) \left( \frac{\lambda - \lambda_{pw}}{\lambda_{re} - \lambda_{pw}} \right) \right) \leq \frac{M_p}{M_{yt}} \]  
   
   \[(F4-16b)\]

2. When \( \frac{I_{yc}}{I_y} \leq 0.23 \)
   
   \[ R_{pt} = 1.0 \]  
   
   \[(F4-17)\]

3. c CLF7: Flexural checks for Square and Rectangular HSS & Box Sections

   - **CLF7.2**: Flange local buckling checks updated to use F7-4 & F7-5 of AISC 360-16 to calculate the effective width of slender elements.
     
     - For HSS
       
       \[ b_c = 1.92 t_f \sqrt{\frac{E}{F_y}} \left( 1 - \frac{0.38}{b/t_f} \sqrt{\frac{E}{F_y}} \right) \leq b \]  
       
       \[(F7-4)\]
     
     - For box sections
       
       \[ b_c = 1.92 t_f \sqrt{\frac{E}{F_y}} \left( 1 - \frac{0.34}{b/t_f} \sqrt{\frac{E}{F_y}} \right) \leq b \]  
       
       \[(F7-5)\]
   
   - **CLF7.3**: Web local buckling checks updated to use F7-6 through to F7-9 of AISC 360-16.
     
     - For sections with noncompact webs
       
       \[ M_n = M_p - (M_p - F_y S) \left( 0.305 \frac{b_c}{t_w} \sqrt{\frac{E}{F_y}} - 0.738 \right) \leq M_p \]  
       
       \[(F7-6)\]
       
       where
       
       \( h \) = depth of web, as defined in Section B4.1b, in. (mm)
     
     - For sections with slender webs
       
       - compression flange yielding
         
         \[ M_n = R_{pg} F_y S \]  
         
         \[(F7-7)\]
       
       - compression flange local buckling
         
         \[ M_n = R_{pg} F_{cr} S_{xc} \]  
         
         \[(F7-8)\]
       
       and
       
       \[ F_{cr} = \frac{0.9 E k_c}{\left( \frac{b}{t_f} \right)^2} \]  
       
       \[(F7-9)\]
       
       where
       
       \( R_{pg} \) = defined by Equation F5-6 with \( a_w = 2h t_w / (bt_f) \)
\[ k_c = 4.0 \]

- CL.F7.4: Lateral torsional buckling checks updated to use F7-6 through to F7-13 of AISC 360-16.

3.d CL.F9: Flexural checks for Tees and Double Angles

- Yielding checks for Tee sections updated to use Eqn F9-4 of AISC 360-16.
- Yielding checks for Double Angle sections updated to use Eqn F9-5 of AISC 360-16.

\[ M_p = 1.5M_y \] (F9-5)

- Lateral torsional buckling checks updated to use Eqns F9-6 through to F9-13 of AISC 360-16
- Flange Local Buckling calculations of Tees and double angle legs updated to include criteria as per CL. F9.3 (b) of AISC 360-16
- Web local buckling checks for Stem of Tee sections updated to use Cl.F9.4 - Eqns F9-17 through to F9-19 of AISC 360-16.
- Web local buckling checks for legs of double angle sections updated to use Cl.F9.4 (b) of AISC 360-16.

3.e CL.F10: Flexural checks for Single Angles

- Lateral Torsional Buckling checks updated to use Eqns F10-4 through to F10-5b of AISC 360-16.

CHAPTER G Shear Checks

4.a CL.G2: I Shapes and Channels

- Calculation of Shear strength coefficient Cv updated to use Eqns G2-2 to G2-4 of AISC 360-16
- Calculation of Shear buckling coefficient kv updated to use Eqns from section G2 of AISC 360-16.
- Criteria for consideration of Tension field action updated as per Section G2.2 of AISC 360-16.
- Shear strength calculations for cases with tension field action updated to use Eqns G2-6 through to G2-11 of AISC 360-16.

D1.A.10.7 Output

Preceding the member output will be a series of design statements regarding axis conventions, nomenclature, notes, and abbreviations.

TRACK 0 Output

This format reports the design summary for a member indicating the pass/fail status, the critical design ratio, the most critical load case ID, and the code clause that produced the critical design ratio.
**TRACK 1 Output**
