Problem
The reference example given in (1) is modelled in STAAD.Pro considering the following:

Seismic zone factor, Z = 0.36
Importance factor, I = 1.2
Response reduction factor, R = 5
Soil site conditions = Hard

The generated model is subjected to a response spectrum load along global X direction. The base shear and its distribution along height reported by STAAD.Pro is verified against hand calculation.

V. IS 1893 2016 Static Seismic

Calculation of base shear and its distribution along the height for equivalent static method in IS 1893 (Part 1): 2016

**Problem**

A reinforced concrete frame structure is 4 bays at 4m ea. by 3 bays at 4m ea. in plan. The structure is 3 stories at 3m ea.

The structure is modelled in STAAD.Pro considering the following:

- Seismic zone factor, $Z = 0.36$ (ZONE 0.36)
- Importance factor, $I = 1.2$ (I 1.2)
- Response reduction factor, $R = 5$ (RF 5)
- Soil site condition = Hard (SS 1)
- Structure type is a reinforced concrete frame (ST 1)

The seismic weight for each floor is assumed as 100 kN applied as joint weight to nodes 39, 60 & 80. Seismic Loads as per IS 1893 (Part 1): 2016 specifications are generated along two horizontal directions global X & global Z and also along vertical direction global Y. The base shear and its distribution along height reported by STAAD.Pro is verified against hand calculation.

Height = 3 × 3 = 9m

$$T_a = 0.075h^{0.75} = 0.075 \times (9^{0.75}) = 0.39 \text{ sec}$$

$$[Sa/g]_x = [Sa/g]_y = 2.5 \text{ (As time period < 0.4 sec)}$$

$$[Sa/g]_y = 2.5 \text{ (constant)}$$
Ah_x = (Z/2) × (I/R) × [Sa/g]_x = 0.36/2 × 1.2/5 × 2.5 = 0.108
Ah_z = (Z/2) × (I/R) × [Sa/g]_z = 0.36/2 × 1.2/5 × 2.5 = 0.108
Av = (2/3) × (Z/2) × (I/R) × [Sa/g]_y = 2/3 × 0.36/2 × 1.2/5 × 2.5 = 0.072
VB = Ah × W or Av × W
VB_x = Ah_x × W = 0.108 × (3 × 100) = 32.4 kN
VBmin_x = 2.4% of W = 2.4 × (3 × 100) / 100 = 7.2 kN
VB_x > VBmin_x
VB_z = Ah_z × W = 0.108 × (3 × 100) = 32.4 kN
VBmin_z = 2.4% of W = 2.4 × (3 × 100) / 100 = 7.2 kN
VB_z > VBmin_z
VB_y = Av × W = 0.072 × (3 × 100) = 21.6 kN

</tbody>
</table>

Total height of the building is 100 ft
Dimension of each floor slab is 20 ft × 10 ft
Floor to floor height for super structure is 10 ft
Floor to floor height for sub structure is 5 ft
GL is located at -2 ft (Y co-ordinate)
Depth of Foundation (DT) is (20-2) = 18 ft = 5.4864 m
All the analytical members are W shaped steel beam (W12X190)
Supports are fixed
The generated model is subjected to joint weight(100kip). The base shear and its distribution along the height is calculated in Global X, Global Z, Global Y direction.

Verification
Design horizontal acceleration coefficient value calculation for above GL and below GL for Global X(Ah), Global Z(Ah), Global Y(Av) direction.

**Related Links**

- [TR.28.2.2 Check Irregularities](on page 2531)

**V. IS 1893 2016 Irregular Modes of Oscillation**

Verify irregular modes of oscillation check in accordance to IS 1893 2016 Part 1 specifications.

**Details**

A three story structure is modelled with floor diaphragms defined at the story levels.
Seismic parameters:

- Seismic Zone Factor, $Z = 0.36$
- Importance Factor, $I = 1.2$
- Response Reduction Factor, $R = 5$
- Site soil conditions: hard soil (SS 1)
- Structure type: other (ST 5)

**Verification**

Since the structure is in Zone V the check has two parts. These include:

1. First three modes together contribute at least 65% mass participation factor in each principal plan direction.
2. The fundamental lateral natural periods of the building in the two principal plan directions are away from each other by at least 10% of the larger value.

Looking at the mass participation factor table in output file following observations are made:
Also, it is observed from mass participation factor table the maximum mass participation for X direction occurs in mode 1 and for Z direction occurs in mode 2. Hence for the second part of the check the period of these modes needs to be checked for being away from each other by at least 10% of the larger value.

**V. IS 1893 2016 Mass Irregularity**

Verify mass irregularity check in accordance to IS 1893 2016 Part 1 specifications.

**Details**

A three story structure is modelled with floor diaphragms defined at the story levels.
Verification Examples
V.06 Loading

Seismic parameters:

Seismic Zone Factor, Z = 0.36
Importance Factor, I = 1.2
Response Reduction Factor, R = 5
Site soil conditions: hard soil (SS 1)
Structure type: other: (ST 5)

*Verification*

Diaphragm 1 = 1st Floor: Weight = 10 x 4 = 40 kN
Diaphragm 2 = 2nd Floor: Weight = 16 x 4 = 64 kN
Diaphragm 3 = 3rd Floor: Weight = 23 x 4 = 92 kN

- TR.28.2.2 Check Irregularities (on page 2531)

V. IS 1893 2016 Re entrant Corners

Verify reentrant corner (plan irregularity) check in accordance to IS 1893 2016 Part 1 specifications.

Details

A two story structure is modelled with diaphragms at the story levels.

Figure 418: Isometric View
Seismic parameters:

- Seismic Zone Factor, \( Z = 0.36 \)
- Importance Factor, \( I = 1.2 \)
- Response Reduction Factor, \( R = 5 \)
- Site soil conditions: hard soil (SS 1)
- Structure type: other (ST 5)

**Verification**

Both diaphragms have the same dimensions and are doubly-symmetric. The overall building width in either direction is 12 m and the potential reentrant corner sides are 4 m. Therefore, the ratio of the \( A/L = 4\ m / 12\ m = 0.333 > 0.15 \).

Thus, each of the four corners are reentrant corners per the IS 1893 2016 code.

V. Moving Load

V. Moving Load Generator

To validate the effect of wheel load assembly on bridge girders simulated by a series of equivalent concentrated loads for a particular wheel position, generated by Moving Load generation option.

Details

A bridge decking system of 10m span is simulated by three longitudinal girder of size 0.3m×0.6m (Concrete) at a spacing of 2m and six transverse girders of size 0.3m×0.45m (Concrete) at a spacing of 2m. Longitudinal girders are pinned support at both the ends.

Vehicle definition – 10 kN and 16 kN per wheel in the Front and Rear Axle respectively. The vehicle width is 1.2m and the axle distance is 1.5m. Starting position is from the end of the deck, aligning the rear axle along the last transverse girder. The direction of movement along the longitudinal girder with an incremental distance of 0.5m.

Validation

Among the generated wheel loads, for the 9th position of the wheel assembly, the structure is analyzed for that generated load. The structure is again analyzed with the static load system equivalent to the generated wheel load and observed the difference in results if any.

![Figure 420: The position of the generated load case 9](image-url)
Note: The postprocessing diagrams in STAAD.Pro show two overlapping 7 kN axle reactions on member 14.

The model uses the moving load generator facility and a static load equivalent to the generated Load Case 9 (i.e., 9th position of the wheel assembly). Both support reactions and joint displacements are compared.

1. Example 4.7, [http://nptel.ac.in/courses/105101004/4](http://nptel.ac.in/courses/105101004/4) (p.36)

**Related Links**
- *TR.32.10.1.2 Response Spectrum Specification per NRC 2005* (on page 2694)
- *Response Spectra tab* (on page 3021)

**Details**

Example 4.7(1) is modeled in STAAD.Pro.

The generated model is subjected to a Response Spectrum Load along global X direction. Time-Acceleration pairs for the spectrum data can be seen in supporting excel file *NRC_Calculation.xlsx* within worksheet named RS Values. The direction factor along global X direction is assumed as 0.5. The base shear reported by STAAD.Pro is verified against hand calculation.

**Validation**

</table>

**Spectrum Data**: Obtain from NRC_Calculation.xlsx within worksheet named RS Values

**Formula**

- Linearly Interpolate acceleration values between 0.3 sec & 0.36 sec to obtain acceleration value for 0.30014 sec.
- Linearly Interpolate acceleration values between 0.06 sec & 0.12 sec to obtain acceleration value for 0.10986 sec.
- Linearly Interpolate acceleration values between 0.06 sec & 0.12 sec to obtain acceleration value for 0.08042 sec.

**Sa**

- 1.50
- 1.40
- 1.10

**Horizontal Seismic Coefficient Cs**

- Cs = (Sa x Direction Factor) = Sa x 0.5
- 249998725
- 1.25
- 1.10

V. NRC 2005 Static Seismic

Calculation of base shear and its distribution along the height for equivalent static force method in NBCC/NRC 2005.

Problem

Structure to be modelled:

- height = 3× 5m = 15m
- plan dimension X = 5m
- plan dimension Z = 5m

Input parameters:

- Seismic acceleration values Sa(0.2) = 0.28, Sa(0.5) = 0.17, Sa(1.0) = 0.11, and Sa(2) = 0.063 (SA1 0.28, SA2 0.17, SA3 0.11, SA4 0.063)
- Importance factor = 1.3 (IE 1.3)
- Site class C (SCL 3)
- Higher mode factor X = 1 (MVX 1)
- Higher mode factor Z = 1 (MVZ 1)
- Numerical reduction coefficient for base overturning X = 1 (JX 1)
- Numerical reduction coefficient for base overturning Z = 1 (JZ 1)
- Ductility-related force modification factor X = 5 (RDX 5)
- Ductility-related force modification factor Z = 5 (RDZ 5)
- Overstrength-related force modification factor X = 5 (ROX 1.5)
- Overstrength-related force modification factor Z = 5 (ROZ 1.5)

The seismic weight for each floor is assumed as 200 kN applied as joint weight of 50kN to nodes 2 3 6 7 9 To 16. Seismic Load as per NBCC/NRC 2005 specifications are generated along horizontal direction global X and global Z. The base shear and its distribution along height reported by STAAD.Pro is verified against hand calculation.

\[ T_{a_X} = 0.075 \times (hn)^{0.75} \] (for concrete moment frames) = 0.075 × 15^{0.75} = 0.571649342 sec

\[ T_{a_Z} = 0.075 \times (hn)^{0.75} \] (for concrete moment frames) = 0.075 × 15^{0.75} = 0.571649342 sec

\[ T_{c_X} \] (Rayleigh method from output file) = 0.467, \( T_{c_Z} \) (Rayleigh method from output file) = 0.467

\[ 1.5 \times T_{a_X} = 0.857474013 > T_{c_X} \] so \( T_{a_{used}} = T_{c_X} = 0.467 \)

\[ 1.5 \times T_{a_Z} = 0.857474013 > T_{c_Z} \] so \( T_{a_{used}} = T_{c_Z} = 0.467 \)

\( F_a = 1 \) (For Site Class = C and Sa(0.2) = 0.28)

\( F_v = 1 \) (For Site Class = C and Sa(1.0) = 0.11)

\[ S(0.2) = F_a \times Sa(0.2) = 1 \times 0.28 = 0.28 \]
\[ S(0.5) = \text{smaller of } F_v \times S_a(0.5) \text{ and } F_a \times S_a(0.2) = \text{smaller of } 1 \times 0.17 \text{ and } 1 \times 0.28 = 0.17 \]
\[ S(T_{\text{used}})_x = S(T_{\text{used}})_z = 0.17 + \frac{(0.28-0.17)}{(0.5-0.2)} \times (0.5-0.467) = 0.1821 \]
\[ V_x = S(T_{\text{used}})_x \times MV_x \times I \times W \div (RDX \times ROX) = 0.1821 \times 1 \times 1.3 \times (200 \times 3) \div 5 \times 1.5 = 18.9384 \text{ kN} \]
Min Base Shear = \[ S(2.0) \times MV_x \times I \times W \div (RDX \times ROX) = 0.063 \times 1 \times 1.3 \times (200 \times 3) \div 5 \times 1.5 = 6.552 \text{ kN} \]
Max Base Shear = \[ 2/3 \times S(0.2) \times I \times W \div (RDX \times ROX) = 2/3 \times 0.28 \times 1.3 \times (200 \times 3) \div 5 \times 1.5 = 19.413 \text{ kN} \]
\[ V_x > \text{Min Base Shear} \text{ & } V_x < \text{Max Base Shear}, \quad V_x = 18.9384 \text{ kN} \]

\[ V_z = S(T_{\text{used}})_z \times MV_z \times I \times W \div (RDZ \times ROZ) = 0.1821 \times 1 \times 1.3 \times (200 \times 3) \div 5 \times 1.5 = 18.9384 \text{ kN} \]
Min Base Shear = \[ S(2.0) \times MV_z \times I \times W \div (RDZ \times ROZ) = 0.063 \times 1 \times 1.3 \times (200 \times 3) \div 5 \times 1.5 = 6.552 \text{ kN} \]
Max Base Shear = \[ 2/3 \times S(0.2) \times I \times W \div (RDZ \times ROZ) = 2/3 \times 0.28 \times 1.3 \times (200 \times 3) \div 5 \times 1.5 = 19.413 \text{ kN} \]
\[ V_z > \text{Min Base Shear} \text{ & } V_z < \text{Max Base Shear}, \quad V_z = 18.9384 \text{ kN} \]

Since fundamental lateral period < 0.7 sec \( F_t = 0 \), calculated Base Shear is distributed along the height as under:
\[ F_x = (V - 0) \times (W_x \times h_x \div \sum W_i \times h_i) = (V) \times (W_x \times h_x \div \sum W_i \times h_i) \]

Details

Example 4.7(1) is modeled in STAAD.Pro.

The generated model is subjected to a Response Spectrum Load along global X direction. Time-Acceleration pairs for the spectrum data can be seen in supporting excel file NRC_Calculation.xlsx within worksheet named RS Values. The direction factor along global X direction is assumed as 0.5. The base shear reported by STAAD.Pro is verified against hand calculation.

Validation

V. NRC 2010 Static Seismic

Calculation of base shear and its distribution along the height for equivalent static force method in NBCC/NRC 2010.

Problem

Structure to be modelled:

- height = 3× 5m = 15m
- plan dimension X = 5m
- plan dimension Z = 5m

Input parameters:

- Seismic acceleration values Sa(0.2) = 0.28, Sa(0.5) = 0.17, Sa(1.0) = 0.11, and Sa(2) = 0.063 (SA1 0.28, SA2 0.17, SA3 0.11, SA4 0.063)
- Importance factor = 1.3 (I 1.3)
- Site class C (SCL 3)
- Higher mode factor X = 1 (MVX 1)
- Higher mode factor Z = 1 (MVZ 1)
- Ductility-related force modification factor X = 5 (RDX 5)
- Ductility-related force modification factor Z = 5 (RDZ 5)
- Overstrength-related force modification factor X = 5 (ROX 1.5)
- Overstrength-related force modification factor Z = 5 (ROZ 1.5)
- Moment resisting frames in both X and Z directions (STX 1, STZ 1)
- Provisions to be checked for member strength (MD 1)

The seismic weight for each floor is assumed as 200 kN applied as joint weight of 50kN to nodes 2 3 6 7 9 To 16. Seismic Load as per NBCC/NRC 2010 specifications are generated along horizontal direction global X and global Z. The base shear and its distribution along height reported by STAAD.Pro is verified against hand calculation.
Ta = 0.075×(hn)$^{0.75}$ (for concrete moment frames) = 0.075 × 15$^{0.75}$ = 0.57 sec
Ta = 0.075×(hn)$^{0.75}$ (for concrete moment frames) = 0.075 × 15$^{0.75}$ = 0.57 sec
Tc (Rayleigh method from output file) = 0.467, Tc (Rayleigh method from output file) = 0.467
1.5 × Ta = 0.86 > Tc so Ta = Tc = 0.467
1.5 × Ta = 0.86 > Tc so Ta = Tc = 0.467

Fa = 1 (For Site Class = C and Sa(0.2) = 0.28)
Fv = 1 (For Site Class = C and Sa(1.0) = 0.11)

S(0.2) = Fa × Sa(0.2) = 1 × 0.28 = 0.28
S(0.5) = smaller of Fv × Sa(0.5) and Fa × Sa(0.2) = smaller of 1 x 0.17 and 1 × 0.28 = 0.17
S(Ta) = S(Ta) = 0.17 + ((0.28-0.17)/(0.5-0.2) × (0.5-0.467)) = 0.1821

Vx = S(Ta) × MVX × I × W / RDX × ROX = 0.1821 × 1 × 1.3 × (200x3) / 5 × 1.5 = 18.9384 kN
Min Base Shear = S(2.0) × MVX × I × W / (RDX × ROX) = 0.063 × 1 x 1.3 × (200x3) / 5 × 1.5 = 6.552 kN
Max Base Shear = 2/3 × S(0.2) × I × W / (RDX × ROX) = 2/3 × 0.28 x 1.3 × (200x3) / 5 × 1.5 = 19.413 kN

Vx > Min Base Shear & Vx < Max Base Shear, Vx = 18.9384 kN

Vz = S(Ta) × MVZ × I × W / RDZ × ROZ = 0.1821 × 1 × 1.3 × (200x3) / 5 × 1.5 = 18.9384 kN
Min Base Shear = S(2.0) × MVZ × I × W / (RDZ × ROZ) = 0.063 × 1 x 1.3 × (200x3) / 5 × 1.5 = 6.552 kN
Max Base Shear = 2/3 × S(0.2) × I × W / (RDZ × ROZ) = 2/3 × 0.28 x 1.3 × (200x3) / 5 × 1.5 = 19.413 kN

Vz > Min Base Shear & Vz < Max Base Shear, Vz = 18.9384 kN

Since fundamental lateral period < 0.7 sec Ft = 0, calculated Base Shear is distributed along the height as under:

Fx = (V - 0) × (Wx × hx / ∑ Wi × hi) = (V) × (Wx × hx / ∑ Wi × hi)

V. Wind Load

V. ASCE 7-10 Wind Load Generation

To validate STAAD.Pro calculated equivalent joint loads for a closed structure subjected to Wind Loading. Wind Intensity is calculated as per ASCE 07 – 2010.

Details

When closed type structures are subjected to wind load, panels or closed surfaces are generated by the program based on the members in the ranges specified and their end joints. Wind load, in such way, is converted to equivalent joint loads and applied on the nodes of that closed surface. The area within each closed surface is determined and the share of this area (influence area) for each node in the list is calculated. Wind intensities have been calculated as per ASCE 07 – 2010. The detailed calculation of determination of equivalent joint loads is performed here in this document.

A two-story, single-bay frame is subjected to wind loading from +X direction. Assumptions made while calculating the wind intensities are tabulated in the Validation section of this document.

Verification

Calculation of Wind Intensity

Assumptions made in determination of wind intensities as per ASCE 07 – 2010

i. Analysis Procedure – Directional Procedure for MWFRS of enclosed buildings, Chapter 27

ii. Type of roof – flat

iii. Building Classification Category = Category II (Table 1.5-1)

iv. Basic Wind Speed = 110 mph

v. Exposure Category = Exposure B (Clause 26.7.3)

vi. Wind speed-up over Hills or Escarpment is not considered

vii. Building Height = 20 ft

viii. Building length along the direction of Wind (L) = 10 ft

ix. Building length normal the direction of Wind (B) = 20 ft

x. Natural Frequency of the building = 2 Hz (Hence, as per clause 26.2, this is a rigid building)

xi. Building Damping Ratio = 0.05

xii. Enclosure Classification = Enclosed Building (Clause 26.10)

xiii. Directionality Factor Kd = 0.85 (Table 26.6-1, for MWFRS)

xiv. Topographic Factor, Kzt = 1 (Clause 26.8.2)

xv. Building Wall to generate Wind Load on – Windward side

xvi. Gust Effect Factor, G = 0.85 (Clause 26.9.1)

xvii. External pressure Coefficient Cp = 0.85 (Windward wall pressure coefficient, as per Table 27.4-1)

xviii. Internal pressure coefficient GCpi = -0.18 (For Enclosed Buildings, Table 26.11-1)

Hence, the velocity pressure exposure coefficients (Kz) are calculated as per the formulae given in Table 27.3-1:

From Table 26.9.1, For Exposure B, α = 7 and zg = 1200 ft
As per clause 27.3.2, velocity pressure $q_z = 0.00256x K_z x K_{zt} x K_d x V^2$ (lb/ft$^2$)

Since Mean roof height $h = $ Height of building = 20 ft

$$q_h = 0.00256x (K_z)_{h=20\ ft} x K_{zt} x K_d x V^2 = 16.42847 \ lb/ft^2$$

Design wind pressure, $p$ is calculated as per clause 27.4.1 as -

$$p = q x G x C_p - q_i x (G Cpi)$$

Values of $q_z$ and $p$ for different heights are calculated using the above formulae and tabulated below.

Procedure Used by STAAD.Pro for Calculating the Equivalent Joint Load from incident Wind Pressure

1. Form closed panels. A closed panel is a region whose boundary consists entirely of members or of members and the ground surface.
2. Find the center of gravity of each of the panels.
3. For each panel, draw straight lines from the center of gravity (CG) to the midpoint of the members that form the panel boundary. So, the panel region will now contain several quadrilaterals whose two sides are made of portions of the respective members (or the ground) and the other two sides are lines going from the CG to the midpoint of the corresponding members.
4. The area contained in any quadrilateral is allocated as the influence area for the node located at the meeting point of two members.
5. Multiply the influence area by the average wind pressure contained inside the influence area and by the exposure factor for the node. This will yield the concentrated wind force for the joint.

Calculation of Equivalent Joint Loads
Evidently, members AB, BG and GH along with the ground surface, forms the closed panel ABGH. P is the CG of the panel, located at 5 ft away from line AH and 5 ft away from line AB. So, influence area for joint A is AJPI. Area of AJPI = 5 x 5 = 25 ft².

Average intensity of wind pressure in this area AJPI = 13.246979 lb/ft²

Exposure factor = 1 (for all the nodes in the model)

So, equivalent joint load in joint A = Influence area x Avg. Intensity of wind pressure x Exposure

= 25 x 13.246979 x 1 = 331.174 lb = 0.331 kip

Joint B will be under influence of influence area BKQU and BKPJ. Area of each of those influence areas = 5 x 5 = 25 ft². Intensity of wind pressure in each of those influence areas = 13.246979 lb/ft². Hence, equivalent joint load for each of those areas = 0.331 kip

So, total joint load in joint B = 0.331 x 2 = 0.662 kip

Joint C will be under influence area CVQU. Average intensity of wind pressure in this influence area will be = \((13.246979 + 14.1284837) / 2 = 13.68773135\) lb/ft²

Exposure Factor = 1

Area of CVQU = 5 x 5 = 25 ft²

Hence, equivalent joint load at joint C = 342.193 lb ≈ 0.343 kip

Joint W will be under influence of area WXRZ and WVQZ. Area of both of these = 25 ft². Average intensity of wind pressure in both of the influence areas = Average intensity of wind in the influence area CVQU = 13.68773135 lb/ft². Hence, equivalent joint load on joint W = 2 x 0.343 kip = 0.686 kip

Joint G will be under the influence of area GZRM, GZQK, GMSL and GKPL. Area of each of these influence areas = 5 x 5 = 25 ft². Average intensity of wind pressure in each of these areas = average intensity of wind pressure in area BKQU = 13.246979 lb/ft². Hence, equivalent joint load on joint G = 4 x 0.331 = 1.324 kip

Joint H will be under the influence of areas HLPI and HTSL. Area of each of those influence areas = 5 x 5 = 25 ft². Intensity of wind pressure in each of those influence areas = 13.246979 lb/ft². Hence, equivalent joint load on joint H = 2 x 0.331 = 0.662 kip

Since the structure is symmetric about the line WH, the equivalent joint load at D = equivalent joint load at C = 0.343 kip, equivalent joint load at B = equivalent joint load at E = 0.662 kip and equivalent joint load at A = equivalent joint load at F = 0.331 kip.

DEFINE WIND LOAD

TYPE 1 WIND 1
<! STAAD PRO GENERATED DATA DO NOT MODIFY !!!
V. Wind On Open Structure

Validate the calculated member loads for an open structure subject to wind loading.

Details

A structure is subjected to wind loading from +X direction. The members are rectangular members with 500 mm × 500 mm in dimension. The diagonal member is also of same dimension but rotated at a beta angle value of 45°. Thus, the wind facing area of that member will be different than that of the other members.

<tr>
<td>10 - 20</td>
<td>3</td>
</tr>
</tbody>
</table>

Validation

When open structures are subjected to wind load, wind load incident on the structure is applied as uniformly distributed loads on the members along the projected axis (i.e., in PX/PY/PZ direction). Wind intensity multiplied by the effective area of the member facing the wind load gives the uniformly distributed member load on the member.

Wind Load on Members 1, 3, 6 & 8

Wind intensity varies between the length of the member, so different parts of the member will be subjected to uniformly distributed loads of different magnitudes.

Let the midpoint of member 1 be K. So, $AK = CK = 5\ m$
Up to Height 5 m (part AK)

Intensity of wind load = 1.5 kN/m^2
Area of the member facing the wind = 0.5 m
\( w_{AK} = 1.5 \times 0.5 = 0.75 \text{ kN/m} \)

Up to Height 10 m (part KB)

Intensity of wind load = 2 kN/m^2
Area of the member facing the wind = 0.5 m
\( w_{KB} = 2 \times 0.5 = 1 \text{ kN/m} \)

Due to same orientation, member load on member 3, 6, and 8 will also be same as that of member 1.

Wind Load on Member 9, 10, 11 & 12

Intensity of wind load = 3 kN/m^2
Area of the member facing the wind = 0.5 m
\( w = 3 \times 0.5 = 1.5 \text{ kN/m} \)

Due to same orientation, member load on member 10, 11, and 12 will also be same as that of member 9.

Wind Load on Member 4 & 5

Intensity of wind load = 2 kN/m^2
Area of the member facing the wind = 0.5 m
\( w = 2 \times 0.5 = 1.0 \text{ kN/m} \)

Due to same orientation, member load on member 5 will also be same as that of member 4.

Wind Load on Member 14 & 15

Intensity of wind load = 3 kN/m^2
Area of the member facing the wind = 0.5 m
\( w = 3 \times 0.5 = 1.5 \text{ kN/m} \)

Due to same orientation, member load on member 15 will also be same as that of member 14.

Wind Load on Member 2, 7, 13, & 16

These members are aligned along the +X axis. Since the structure is subjected to wind load from +X direction only, the area of those members facing the wind is zero. So, there will be no load due to wind on these members.

Wind Load on Member 17

Since the member is rotated at a beta angle of 45°, the area of the member facing the wind = \( 0.5 \text{ m} / \cos 45° = 0.707 \text{ m} \)

Wind intensity varies between the length of the member, so different parts of the member will be subjected to uniformly distributed loads of different magnitudes.

Up to height 5m

Wind intensity = 1.5 kN/m^2
\( w = 1.5 \times 0.707 = 1.061 \text{ kN/m} \)

Up to height 10m
Wind intensity \(= 2 \text{kN/m}^2\)
\[ w = 2 \times 0.707 = 1.414 \text{kN/m} \]

Results from hand calculation

**At Load Step 3**

Equation of elastic deflection at cantilever tip:

\[ \delta_z = \frac{PL}{3EI} + \frac{PL}{GA_v} \]

where

\[
\begin{align*}
P &= 57.837 \text{ kip} \\
L &= 24 \text{ in.} \\
E &= 29,000 \text{ ksi} \\
I &= 138.0 \text{ in.}^4 \\
G &= 11,154 \text{ ksi} \\
A_v &= 10.4323 \text{ in.}^2
\end{align*}
\]

Thus elastic deformation:

\[
\delta_z = \frac{57.837 \times 24}{3 \times 29,000 \times 138} + \frac{57.837 \times 24}{11,154 \times 10.4323} = 0.066 + 0.012 = 0.078 \text{ in.}
\]

**At Load Step 13**

Equation of elastic deflection at cantilever tip

\[ \delta_z = \frac{PL}{3EI} + \frac{PL}{GA_v} \]

where

\[
\begin{align*}
P &= 79.479 \text{ kip}
\end{align*}
\]

(The other values are as listed for Load Step 3)

Thus elastic deformation at cantilever tip:

\[
\delta_z = \frac{79.479 \times 24}{3 \times 29,000 \times 138} + \frac{79.479 \times 24}{11,154 \times 10.4323} = 0.092 + 0.016 = 0.108 \text{ in.}
\]

Plastic rotation = 0.04 radian.

Since STAAD.Pro assumes small displacements (\(\sin \theta = \theta\)), plastic deformation at cantilever tip

\[ \delta_z \text{ plastic} = L \times \theta = 24 \times 0.04 = 0.96 \text{ inch} \]

Total deflection = \( \delta_z \text{ elastic} + \delta_z \text{ plastic} = 0.108 + 0.96 = 1.068 \text{ inch} \)
Comparison

STAAD.Pro 3591 User Manual
V.08 Dynamic Analysis

V. Natural Frequency of a 2D Truss

To calculate the Natural frequency of vibration for a two story truss.

Reference
Hand calculation using known formula.

Problem
Find the natural frequency of vibration, $f$, of the truss.

Figure 425: Space truss

E = 30,000 ksi
L = 10 ft
P = 10 kips
All members are L4x4x5/16
Hand Calculation

Calculate average deflection at top:

$$\delta_{avg} = \frac{(0.45255 \text{ in} + 0.43535 \text{ in})}{2} = 0.444 \text{ in}$$

Stiffness of truss:

$$k = \frac{P}{\delta_{avg}} = \frac{20.0 \text{ kip}}{0.444 \text{ in}} = 45.5 \text{ k/in}$$

Mass:

$$M = \frac{w}{g} = \frac{20.0}{386.4} = 0.05175 \text{ k-sec}^2/\text{in}$$

Frequency:

$$f = \frac{\sqrt{k/m}}{2\pi} = \frac{\sqrt{45.057/0.05175}}{2\pi} = 4.696 \text{ Hz}$$

Comparison

V. First Modal Frequency of a Cantilever Beam

To calculate the Natural frequency of vibration for a rectangular cantilever beam with a mass at the free end.

Reference
Hand calculation using known formulas.

Problem
Find the natural frequency of vibration, \( \omega \), of the cantilever beam.
Figure 426: Model for dynamic beam no. 1

- E = 30,000 ksi
- h = 12.0 in
- b = 6.0 in
- W = 10.0 k
- L = 120 in

**Hand Calculations**

Stiffness at free end:
\[
k = \frac{3EI}{L^3} = 45 \text{ k/in}
\]

Mass
\[
m = \frac{w}{g} = \frac{10.0 \text{ k}}{386.4 \text{ k·sec}^2/\text{in}} = 0.02588 \text{ k·sec}^2/\text{in}
\]

Circular frequency:
\[
\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{45}{0.02588}} = 41.7 \text{ rad/sec}
\]
\[
= 6.637 \text{ cycles/sec}
\]

V. Natural Frequency of Beam on Springs

Find the period of free vibration for a beam supported on two springs with a point mass.

Reference

Problem

A simple beam is supported by two spring as shown in the figure. Neglecting the distributed mass of the beam, calculate the period of free vibration of the beam subjected to a load of $W$.

\[
\begin{align*}
EI &= 30,000.0 \text{ ksi} \\
A &= 7.0 \text{ ft} \\
B &= 3.0 \text{ ft.} \\
W &= 1,000 \text{ lbf} \cdot K = 300.0 \text{ lb/in.}
\end{align*}
\]

V. Modal Frequencies of a Simply Supported Beam

To find the natural frequencies of vibration for a simply supported beam.

Reference

Problem

Find the first five flexural natural frequencies of the simple beam. Neglect shear deformation and rotary inertia.

\[
\begin{align*}
E &= 10,000 \text{ ksi} \\
\text{density} &= 0.1 \text{ lb/in}^3 \\
A_x &= 2.0 \text{ in}^2 \\
I_x &= 0.6667 \text{ in}^4 \\
L &= 20 \text{ in}
\end{align*}
\]

*Figure 431: Model for dynamic beam no. 7*
Hand Calculations

Weight

\[ w_{\text{weight}} = A \times \text{density} = 2.0 \times (0.1) = 0.2 \text{ lb/in} \]
\[ w_{\text{mass}} = 0.2 / (386.4) = 0.000518 \]

From Table 36, Item 1b of the reference:

\[ f_n = \frac{k_n}{2\pi} \sqrt{\frac{EI}{w_l^4}} = \frac{k_n}{2\pi} \sqrt{\frac{10(10)^3(0.6667)}{0.000518(20)^4}} = 45.16 \cdot k_n \]

MASS PARTICIPATION FACTORS

--------------------------
| MASS PARTICIPATION FACTORS IN PERCENT |
--------------------------
V. Modal Response of a Beam

Find the natural frequencies for a beam and compare theoretical answers to the STAAD.Pro solution.

Reference

Problem
The first five natural frequencies and the associated mode shapes are computed for the flexural motion of a simply supported beam.

![Simple beam diagram](image1)

**Figure 432: Simple beam diagram**

L = 20 in

![Finite element model](image2)

**Figure 433: Finite element model**

The simply supported beam is divided into twenty spanwise beam elements. At nodes 1 and 21, all degrees of freedom except the rotation about the Z axis are restrained. For the remaining nodes, only the translation along Y and the rotation about Z are permitted. Both shear deformation and rotary inertia have been excluded from the model. The mass matrix is a diagonal matrix.

Cross-section Properties
Rectangular Section: 1 inch Width x 2 inch Depth

Area = 2 in²

\[
J = \frac{b^3}{16} \left\{ \frac{16}{3} + 3.36 \left( \frac{b}{a} \right) \left[ 1 - \frac{1}{12} \left( \frac{b}{a} \right)^4 \right] \right\}
\]

where

\[
\begin{align*}
a & = 2 \\
b & = 1
\end{align*}
\]
Theoretical Results

The natural bending frequencies, for a uniform beam with hinged ends, are given by:

\[ f_n = \frac{n^2 \pi^2}{2l^2} \sqrt{\frac{El}{A \gamma}} \]

where

- \( f_n \) = natural frequency for mode \( n \), in cycles per second
- \( l \) = span of the beam
- \( E \) = elastic modulus
- \( I \) = cross-section moment of inertia
- \( g \) = gravitational constant
- \( A \) = cross-section area
- \( \gamma \) = weight density

The parameters used in the frequency equation are:

- \( l = 20 \text{ in} \)
- \( E = 10 \times 10^6 \text{ psi} \)
- \( I = 0.6667 \text{ in}^4 \)
- \( g = 386.4 \text{ in}/s^2 \)
- \( A = 2.0 \text{ in}^2 \)
- \( \gamma = 0.1 \text{ lbs/in}^3 \)

from which:

\[ f_n = n^2 \times 445.686 \]

Comparison

The table below shows the natural frequencies computed from the theoretical equation and the subspace iteration method available within STAAD.Pro. Frequencies are in cycles per second.

V. Modal Response of a Circular Plate

Find the natural frequencies of a circular plate and compare theoretical answers to the STAAD solution.

Reference

Problem
A flat circular plate is simply supported around the entire perimeter. The first six modes and their associated natural frequencies are to be computed using the subspace iteration method offered by STAAD. This problem demonstrates that the natural frequencies of an axi-symmetric structure can be accurately computed utilizing a 180 degree model with the appropriate boundary conditions.

The 180 degree sector was modeled using radial lines at intervals of 15 degrees. Tangential lines were then located utilizing a relationship such that the aspect ratio of the quad-plate elements was approximately 1.0. All rotations normal to the plane of the plate were restrained. In-plane translations for all nodes were restrained.
because the theoretical solution does not consider in-plane effects. Rotations about the global Y axis for the nodes at X=0.0 were restrained because this is a symmetry boundary. Z translation of all nodes on the outside radius were restrained to provide for the simply-supported condition.

\[ f_{ij} = \frac{\lambda_{ij}^2}{2na^2} \sqrt{\frac{Eh^3}{12\gamma(1-\nu^2)}} \]

= dimensionless parameter associated with the mode indices i, j

where

- \( i \) = number of nodal diameters in this mode shape
- \( j \) = number of nodal circles in this mode shape not counting the boundary
- \( \nu \) = Poisson's ratio
- \( E \) = elastic modulus
- \( h \) = plate thickness
- \( \gamma \) = mass of plate per unit area
- \( a \) = radius of plate

The numerical values used for this example are:

- \( \nu = 0.30 \)
- \( E = 10.0 \times 10^6 \) psi
\[ h = 0.10 \text{ inches} \]
\[ \gamma = \frac{(0.10 \text{ lb}_m \text{ in}^3)(0.10 \text{ in})}{(386.4 \text{ lb}_m \cdot \text{ in/lb}_f \cdot \text{s}^2)} = 2.588 \times 10^{-5} \text{ in/lb}_f \cdot \text{s}^2 \text{ in}^3 \]
\[ a = 10.0 \text{ inches} \]

with the numerical values used above

\[ \frac{1}{2n^2} \sqrt{\frac{E h^3}{12(1 - \nu^2)}} = \frac{1}{2n(10.0)^2} \sqrt{\frac{(10.0 \cdot 10^6)(0.10)^3}{12(2.588 \cdot 10^{-5})(1 - (0.3)^2)}} = 9.467 \text{ cycles/sec.} \]

\[ \lambda^2_{ij} \] is tabulated from the reference as follows:

</table>
*The reference did not tabulate a value of for the fifth mode of the structure, hence a comparison with the theoretical value of this mode cannot be made.

All anti-symmetric mode shapes for the 360 degree circular plate were captured by the 180 degree model with a phase angle included in the calculation. Some of the difference between the theoretical and STAAD.Pro frequencies is attributed to the loss of mass due to the piecewise secant representation of the outer radius and, since this mass is about 1 percent lower than for a true circular plate, it is not surprising that the first few modes are lower than the theoretical solution.

V. Modal Response of a Rectangular Plate

Find the natural frequencies of a rectangular plate and compare theoretical answers to the STAAD.Pro solution.

Reference

Problem
A flat rectangular plate is simply supported on all four sides. The first six modes and their associated natural frequencies are to be computed for this structure using the subspace iteration method offered by STAAD.Pro. This problem also demonstrates that the mesh refinement can be chosen to accurately calculate modes of interest based on the expected mode shapes.

![Figure 436: Simply supported, rectangular plate](image)

L = 45 in., W = 30 in., t = 0.2 in.

A plate with an aspect ratio of 1.5 was used so that comparison could be made with theoretical results tabulated for plates in the reference. An equally spaced mesh was utilized in both the x and the y dimensions of the plate. The number of elements in each dimension was determined on the basis of the highest mode of interest. Since
the number of half-waves in the sixth mode is 3 in the length dimension and 2 in the width dimension, a node spacing of 3.75 inches results in each half-wave being represented by four elements which means that no element will be expected to deform in double curvature. The simply supported edge condition requires that translation normal to the plane of the plate be restrained for these edge nodes. Rotations normal to the plate were restrained for all nodes.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{modelFinite.png}
\caption{Model: finite element meshed}
\end{figure}

Theoretical Calculations

From the reference case 16 in Table 11-4, the first six natural frequencies of the plate are described by the following equations:

\[ f_{ij} = \frac{\lambda_{ij}^2}{2na^2} \sqrt{\frac{Eh^3}{12\gamma(1 - \nu^2)}} \]

where

\begin{align*}
  i & = \text{number of half-waves in this mode shape along the horizontal axis} \\
  j & = \text{number of half-waves in this mode shape along the vertical axis} \\
  \nu & = \text{Poisson's ratio} \\
  E & = \text{elastic modulus} \\
  h & = \text{plate thickness} \\
  \gamma & = \text{mass of material per unit area} \\
  a & = \text{length of plate} \\
  b & = \text{width of plate}
\end{align*}

The numerical values used for this example are:

\begin{align*}
  \nu & = 0.30 \\
  E & = 30.0 \times 10^6 \text{ psi} \\
  h & = 0.2 \text{ inches} \\
  \gamma & = \left( \frac{0.282 \text{ lb}_m}{\text{in}^3} \right) \left( 0.20 \text{ in} \right) \left( \frac{386.4 \text{ lb}_m \cdot \text{in/lb_f} \cdot \text{s}^2}{\text{in}^3} \right) = 0.146 \times 10^{-4} \text{ in/lb_f} \cdot \text{s}^2 \\
  a & = 45.0 \text{ in} \\
  b & = 30.0 \text{ in}
\end{align*}
with the numerical values used above

\[
\frac{1}{2\pi a^2} \sqrt{\frac{Eh^3}{12(1-v^2)}} = \frac{1}{2\pi (10.0)^{2}} \sqrt{\frac{(30.0 \cdot 10^6)(0.20)^3}{12(1.460 \cdot 10^{-4})(1 - (0.3)^2)}} = 0.9644 \text{ cycles/sec.}
\]

\(\lambda^2_{ij}\) is tabulated from the reference as follows:

**Table 492: Values of \(\lambda^2_{ij}\)**

</table>

As noted earlier, the node spacing was based on the highest mode of interest. It follows that the difference between the theoretical and STAAD.Pro frequencies generally increases with increasing mode sequence.

V. Modal Response of a 3D Frame

Find the natural frequencies of a space frame. Compare the results from subspace iteration method used by STAAD.Pro with the results from EASE2® and ANSYS®.

Reference
1. Problem 1, from the ASME 1972 Program Verification and Qualification Library

Problem
A three dimensional frame is analyzed for its natural frequencies and the associated mode shapes using the subspace iteration method offered by STAAD.Pro.
Figure 438: Frame model

L1 = 8.625 ft
L2 = 10 ft

All dimensions are in inches.

The only entity present in the model is the general purpose three dimensional beam.

Cross-section Properties

All the beam elements have the same cross section:

Outside radius, \( R_o = 1.1875 \text{ in.} \)
Inside radius, \( R_i = 1.0335 \text{ in.} \)
Area, \( A = \pi (R_o^2 - R_i^2) = 1.074532 \text{ in}^2 \)
Moment of Inertia, \( I = \pi / 4 (R_o^4 - R_i^4) \)
\[ I = 0.665747 \text{ in}^4 \]
Torsion constant = twice the inertia, for closed circular sections = \( 1.331494 \text{ in}^4 \)
The expression for the shear flexibility factor is derived from the ratio of maximum shear stress to the average shear stress:

\[
\alpha = \frac{AQ}{Ib}
\]

Where the four items – A, Q, I, and b are properties of the half cross-section about the centerline. For the circular section they are:

\[
A = \frac{\pi}{2}(R_o^2 - R_i^2)
\]

\[
Q = \frac{2}{3}(R_o^3 - R_i^3)
\]

\[
I = \frac{\pi}{8}(R_o^4 - R_i^4)
\]

\[
b = 2(R_o - R_i)
\]

The final expression for the shear flexibility factor, for a circular tube section is:

\[
\alpha = \frac{A}{b} = \frac{4}{3} \frac{R_o^3 - R_i^3}{(R_o^2 - R_i^2)(R_o - R_i)}
\]

\[
\alpha = 1.993620
\]

Hence the shear area is entered as

\[
AY = \text{Cross Section Area} / \alpha = \frac{1.074532}{1.99362} = 0.538985 \text{ in}^2
\]

Comparison

The following table compares Twenty-Four Natural Frequencies

</table>
In both references by DeSalvo and Swanson\textsuperscript{2} and Peterson\textsuperscript{3}, the number of dynamic degrees of freedom has been reduced from 42 to 24, by means of the Guyan method. No such reduction is performed in the STAAD.Pro model.

V. Beam Subject to response spectrum

Find the maximum moment due to the time history loading and compare theoretical answers to the STAAD solution.

Reference

Problem

The supports of a simply supported beam are subjected to an acceleration time history. The maximum bending moment in the beam is computed for the first mode of the structure. This problem demonstrates the capabilities of STAAD to calculate the correct modal response of a structure utilizing response spectrum data.

![Figure 439: Simple span beam](image)

$L = 240$ in.

The STAAD model consists of 11 nodes and 10 elastic beam elements. Node 1 is completely restrained with the exception of having rotational freedom in the Z direction, the remaining nodes are restrained except for X and Y displacements and Z rotations. Node 11 is additionally restrained against displacements in the Y direction to provide for the simple support condition. Only the contribution of the first mode of the structure is considered.

![Figure 440: Finite element model](image)

**Theoretical Solution**

Material Properties

$E = 30 \times 10^6$ lb/in$^2$

$EI = 1.0 \times 10^{10}$ lb-in$^2$

$m = 0.2$ lb-sec$^2$/in$^2$

$h = 14.0$ in.

From Reference 2, Table 8-1, page 108, the fundamental frequency of the beam is:
\[ f_i = \frac{\lambda_i^2}{2n l^2} \sqrt{\frac{E I}{m}} = \frac{9.869}{2n(240)^2} \sqrt{\frac{1.0(10)^{10}}{0.2}} = 6.098 \text{Hz} \]

The modal participation factor for the fundamental mode is:

\[ \Gamma = \frac{\int_0^1 m \phi(x) \, dx}{\int_0^1 m \phi^2(x) \, dx} \]

Where the first mode shape, \( \phi(x) = \sin(\pi x / l) \)

\[ \Gamma = \frac{\int_0^1 m \sin \left( \frac{\pi x}{l} \right) \, dx}{\int_0^1 m \sin^2 \left( \frac{\pi x}{l} \right) \, dx} = \frac{4}{\pi} \]

The maximum relative modal displacement is given by:

\[ A_{\text{max}} = \Gamma u_{\text{max}} \]

where

\[ u_{\text{max}} = \frac{y''_{\text{so}}}{\omega^2 (\text{DLF})_{\text{max}}} \]
\[ \omega = 2\pi \times 6.098 \text{Hz} \]
\[ y''_{\text{so}} = 1.0g \]
\[ (\text{DLF})_{\text{max}} = 1.648 \text{ at } 6.098 \text{ Hz} \]

therefore:

\[ A_{\text{max}} = 4(1.648)(386.4) / [\pi(2\pi)^2(6.098)^2] = 0.5523 \text{ in.} \]

The bending moment

\[ M = -E I \frac{\delta^2 u}{(\delta x)^2} \]

Where \( u \) for the first mode = \( A \sin(\pi x / l) \)

\[ \delta^2 u / (\delta x)^2 = -\pi^2 l^2 A \sin(\pi x / l) \]
\[ M = A E I \left( \frac{\pi^2 l^2}{2} \right) \sin(\pi x / l) \]
\[ M_{\text{max}} = A_{\text{max}} E I \left( \frac{\pi^2 l^2}{2} \right) \]

at x = l/2

\[ M_{\text{max}} = 1(10)^{10} \times (0.5523) \times \pi^2 / (240^2) = 946.351(10)^3 \text{ lb in} \]

at x = l/2

V. Steady State Loading on a Beam

Calculate the deflections at two points along the beam at steady-state condition.

Reference

### Problem
Determine the steady-state displacements of the quarter and mid-span points of a fixed-fixed beam subjected to a parabolically varying distributed load operating at a 7.5 Hz frequency.

![Beam with harmonic distributed load](image)

**Figure 441: Beam with harmonic distributed load**

![Model: divide span 20@10.0”](image)

**Figure 442: Model: divide span 20@10.0”**

- $E = 10.0 \times 10^6$ psi
- $L = 200$ inches
- $I = 2/3$ in$^4$
- $A = 2$ in$^2$
- $P_0 = 0.1$ lbf/in$^3$
- $g = 386.4$ in/sec$^2$

The DYNRE2 run utilizes all 19 modes calculated by STAAD (Steady State analysis) for which a value of $1.0(10)^{-10}$ times critical damping is assigned. A single forcing frequency equal to 7.5 Hz is specified for the distributed load. This load is distributed to the nodes by calculating the total integrated load for each beam and lumping one-half of this force to the respective i and j nodes.

$$F_i = F_j = \frac{x_j}{x_i} P(x) \frac{d}{dx} x = \frac{1}{2} \frac{x_j}{x_i} \frac{4}{l^2} \left(x_1 - x^2\right) dx$$
Theoretical Solution

The theoretical solution for this example is taken from:

The natural frequencies of the system are calculated using the equations from reference 1 page 108 and reference 2 page 85.

\[ f_i = \frac{\lambda_i^2}{2\pi l^2} \sqrt{\frac{EI}{m}} \]

where

\[ m = \rho A / g \]

\[ f_i = \lambda_i^2 \frac{1}{2\pi(200)^2} \sqrt{\frac{1.0(10)^6(2 / 3)}{0.10(2.0 / 386.4)}} \]

= 4.5156271*10^{-1}\lambda_i^2

\( \lambda_i \) satisfies the characteristic equation:

\[ \cos \lambda_i \cosh \lambda_i - 1 = 0 \]

Table 496: Calculated natural frequency for each mode

<td>26.70354</td>
<td>2023.185</td>
<td>321.9998</td>
</tr>
</tbody>
</table>

The mode shapes are:

\[ \phi_i = \cosh \frac{\lambda_i}{l} - \cos \frac{\lambda_i}{l} - \sigma_i \left( \sinh \frac{\lambda_i}{l} - \sin \frac{\lambda_i}{l} \right) \]

Where:
\[ \sigma_i = \frac{\cosh \lambda_i - \cos \lambda_i}{\sinh \lambda_i - \sin \lambda_i} \]

The response of mode i to a harmonic force:
\[ \eta_i = \frac{\int \phi_i(x) P(x) \, dx}{\omega_i^2 \{ \phi_i(x) \}^2 \, dx} - \frac{\sin(\omega t - \psi_i)}{\sqrt{1 - \frac{\omega^2}{\omega_i^2} + \left( \frac{\kappa \omega}{\pi} \right)^2}} \]

Where \( \psi_i \) is the response phase lag relative to the applied force and c is the damping.

Since \( c = 0.0 \), \( \psi_i = 0.0 \)

Upon substitution and rearranging terms:
\[ \eta_i = \frac{\int l \phi_i(x) P(x) \, dx - \frac{1}{\omega_i} \int \phi_i(x)^2 \, dx \sin \omega t}{\frac{\pi}{l^2} \left( \frac{\omega_i}{\omega^2} - \omega^2 \right) \int \phi_i(x)^2 \, dx} \]

From reference 1, page 466, case c and page 467, case 29:
\[ \frac{4P_o}{\lambda_i^2} \int x \phi_i(x) \, dx - \frac{4P_o}{l^2} \int x^2 \phi_i(x) \, dx = \frac{8P_0}{\lambda_i^2 \beta_i} \left[ 1 + \left( -i \right)^i \right] - \frac{8(-i)^i P_o}{\lambda_i^2 \beta_i^2} \left[ 2 - \sigma_i \beta_i \right] \]

Since the load is symmetric, this expression is zero for \( I = 2, 4, 6 \ldots \); Therefore, \( i = 1, 3, 5 \ldots \) and: \( (-1)^i = -1 \)

And from the reference, \( \beta_i = \frac{\lambda_i}{l} \)

So:
\[ \int \phi_i(x) P(x) \, dx = \frac{16P_o l}{\lambda_i^2} \]

From Reference 1, page 457 case 5:
\[ \int \phi_i(x)^2 \, dx = 1 \]

Therefore:
\[ \omega = 7.5(2\pi) = 47.1239 \text{ radians/sec} \]

\[ \eta_i = \frac{16P_o}{m\lambda_i^2 \left( \omega_i^2 - \omega^2 \right)} \sin \omega t = \frac{16(-1.0) \sin \omega t}{\frac{386.4}{\lambda_i^2 \left( \omega_i^2 - 2 \right) \cdot 220.661^2}} = \frac{16(1.0) \sin \omega t}{\lambda_i^2 \left( \omega_i^2 - 2 \right) \cdot 220.661} \]

V.09 Steel Design
V. Australia
V. Steel Design per AS 4100-1998
V. AS4100 1998 - Bending Capacity

To check the bending capacity of the UB shape per AS4100-1998.

Reference

Problem
Check the suitability of a 360UB50.7 Grade 300 for the beam in Example 5.2 of the reference. This solution relies mainly on AS 4100 and minimally on AISC [1999a], for example, to get basic section properties. Omit deflection checks.

Comparison
Table 500: Comparison of results

STAAD.Pro 3642 User Manual
V. AS4100 1998 - Combined Compression and Bending Capacity

To check the capacity of a member in axial compression plus bending per AS4100-1998.

Reference

Problem
Verify the capacity of the beam-column which uses a UC section in Grade 300 steel. The column is fixed at the base and braced at mid-point in weak-axis bending only. The top of the column is pinned and laterally restrained by braces. Beam B1 and B2 are connected to the column using simple construction to AS 4100 Clause 4.3.4.

Permanent Loads:
- From Beam B1: Py = 260 kN, Mz = -52 kN·m
- From Beam B2: Py = 78.1 kN, Mx = 6.248 kN·m

Imposed Loads:
- From Beam B1: Py = 190 kN, Mz = -38 kN·m
- From Beam B2: Py = 60 kN, Mx = 41.8 kN·m

Verification Examples

V.09 Steel Design

STAAD.Pro 3649 User Manual
V. Canadian

V. CAN/CSA S16-01

In the next few pages are included several verification examples for reference purposes. Since the S16-01 code is similar in many respects to the previous edition of the code (CAN/CSA S16.1-94), the solved examples of the 1994 edition of the CISC Handbook have been used as reference material for these examples.

V. CSA S16-01 - Cantilever with Biaxial Loading

A slender, cantilever beam subjected to a uniform load. Static analysis, 3D beam element.

Reference

Problem

A cantilever beam of length 4 meter is subjected to uniformly distributed load of 3 KN/Meter in both major and minor axis. Axial compression of 8 KN is also applied to the member. User defined steel section Sect_Class-4 from is assigned to the member.

Given

Design forces

- 8.0 KN (Compression)
- 6.0 KNm (Bending-Y)
- 6.0 KNm (Bending-Z)
- 6.0 KN (Shear-Y)
- 6.0 KN (Shear-Z)

Section Properties(Sect_Class-4):
Area = 2766 mm²
Depth of section, D = 150 mm
Thickness of web Tw = 7 mm
Width of flange Bf = 150 mm
Thickness of flange Tf = 6 mm
Moment of inertia about Z axis, Iz = 1086.96 × 10⁴ mm⁴
Moment of inertia about Y axis, Iy = 337.894 × 10⁴ mm⁴
Moment of inertia about X axis, Ix = 3.7378 × 10⁴ mm⁴
Warping constant, Cw = 1.752 × 10¹⁰ mm⁶

Member Length L = 2 m, Unbraced length = 100 mm.

Material
FYLD = 300 MPa
E = 2.05E+05 MPa
G = E/2.6 MPa

Solution

Slenderness Ratio
Effective Length factor along Local Y-Axis = KY = 1
Effective Length factor along Local Z-Axis = KZ = 1
Slenderness ratio about Z axis, L/Rz = 31.9
Slenderness ratio about Y axis, L/Ry = 57.22
Maximum Slenderness Ratio, L/Rmax = 57.22

Section Classification
Bf/Tf = 150×0.5/6 = 12.5 > 200/sqrt(Fy) = 11.54
Flange is Class 4.
d/Tw = (150-2.0×6)/7 = 19.714
(1100/sqrt(Fy))*(1-0.39*Cf/ϕ*Cy)=(1100/sqrt(300))*(1-0.39*8000/(0.9*2766*300)) = 63.24
Web is Class 1.
Overall section is Class 4 section.

Check against axial compression (Clause 13.3.3)
Effective width, Beff = 200*Tf/sqrt(300) = 69.24
Effective area, Aeff = 69.24×6×4+(150-2×6)×7 = 2627.76 mm⁴.
Effective yield stress, FYLDeff =40000/(0.5*Bf/Tf)⁴ = 256 MPa.
As per Clause 13.3.3(a),
Elastic critical buckling, Fe = π⁴×E/L,Rmax⁴ = 617.956 MPa.
Non-dimensional slenderness ratio, $\lambda = \sqrt{\frac{FYLD}{Fe}} = 0.697$

Axial compressive resistance, $Cr = \phi \cdot A_{eff} \cdot FYLD \cdot (1+0.697^{2 \cdot 1.34})^{-1/1.34} = 557886.104 \text{ N.}$

As per Clause 13.3.3(b),

Elastic critical buckling, $Fe = \frac{\pi^4 \cdot E}{L_{Rmax}^4} = 617.956 \text{ MPa.}$

Effective non-dimensional slenderness ratio, $\lambda_{eff} = \sqrt{\frac{FYLD_{eff}}{Fe}} = 0.644$

Axial compressive resistance, $Cr = \phi \cdot A_{eff} \cdot FYLD_{eff} \cdot (1+0.644^{2 \cdot 1.34})^{-1/1.34} = 521726.94 \text{ N.}$

Axial compressive resistance $\text{Min}(557886.104, 521726.94) = 521726.94 \text{ N.}$

Check against bending (Clause 13.5(c))

As the web of the section meets the requirement of Class 3 and flange exceeds Class 3 limit, flexural resistance should be calculated as per clause 13.5(c).iii.

Effective moment of inertia about Z axis,

$$I_{zeff} = \frac{2 \cdot (2 \cdot 69.24 \cdot 6^3)}{12} + \frac{2 \cdot (2 \cdot 69.24 \cdot 6) \cdot (150-6) \cdot (150-6) / 4 + (7 \cdot (150-2 \cdot 6)^3) / 12}{10152591.12 \text{ mm}^4}. $$

Effective section modulus about Z axis,

$$S_{zeff} = 10152591.12 \cdot 2 / 150 = 135367.88 \text{ mm}^3.$$  

Effective moment of inertia about Y axis,

$$I_{yeff} = \frac{(2 \cdot 6 \cdot (2 \cdot 69.24)^3)}{12} + \frac{(0.5 \cdot (150-6)^3)}{12} = 2657648.856 \text{ mm}^4. $$

Effective section modulus about Y axis,

$$S_{yeff} = 2657648.856 / 69.24 = 38383.144 \text{ mm}^3.$$  

Major axis bending resistance if member is laterally supported,

$$Mrz1 = \phi \cdot S_{zeff} \cdot FYLD = 0.9 \cdot 135367.88 \cdot 300 = 36549327.6 \text{ N-mm.} $$

Minor axis bending resistance,

$$Mry = \phi \cdot S_{yeff} \cdot FYLD = 0.9 \cdot 38383.144 \cdot 300 = 10363448.88 \text{ N-mm.} $$

If the member is laterally unsupported major axis bending resistance is determined by clause 13.6(b).

As the value of one of the end moments is 0.0, $\omega_2 = 1.75.$

Where, as per clause 13.6(a),

$$Mu = (1.75 \cdot 3.14 / 2000) \cdot \sqrt{(205000 \cdot 337.894 \cdot 10^{14} \cdot 78846.154 \cdot 3.7378 \cdot 10^4 + (3.14 \cdot 205000 / 2000) \cdot 337.894 \cdot 10^{14} \cdot 1.752 \cdot 10^9)} \cdot 2.48 \cdot 10^8 $$

$$My = Sz \cdot FYLD = (1086.96 \cdot 10^4 \cdot X2 / 150) \cdot 300 = 43478400. $$

Since $Mu > 0.65My,$

Moment of resistance $Mrz2 = 1.15 \cdot 0.9 \cdot 43478400 \cdot (1 - 0.28 \cdot 43478400 / 2.48 \cdot 10^8) = 42791153.71 \text{ N-mm = 42.79 KN-m.}$

$Mrz2$ should not be more than $Mrz1.$ Since, $Mrz2 > Mrz1$ in this example, $Mrz2 = Mrz1.$

$Mrz2 = 36549327.6 \text{ N-mm = 36.549 KN-m}$
Comparison

V. CSA S16-01 - Wide Flange Beam Interaction Ratio 1

Reference

Problem

Find the interaction ratio, beam resistance and beam deflection.

Given

\[ E = 200000 \text{ MPa (STEEL)} \]
\[ F_y = 300 \text{ Mpa CSA G40.21-M} \]

Simply supported beam has a 8.0 m span; Ky is 1.0, Kz 1.0, unsupported length 1.0 m

Allowable Live Load deflection, L/300 = 8000/300 = 27 mm

Factored Uniform Load IS 7 kN/m DEAD, 15 kN/m LIVE.

Steel section is W410X54

V. CSA S16-01 - Wide Flange Beam Interaction Ratio 2

Reference

Problem

Find the interaction ratio, beam and column resistance.

Given

\( E = 200,000 \) MPa (STEEL).
\( F_y = 300 \) MPa   CSA G40.21-M

Simply supported beam/column has a 3.7 m span, Ky is 1.0, Kz 1.0. Factored axial load is 2000 kN and end moments of 200 kN·m and 300 kN·m.

Steel section is W310X118

V.CSA S16-09 - Axial Tension

Design of a double-angle member subject to tension load.

Reference

Problem
Design a tension diagonal in an all-welded truss (SNU 0 for welded). Attached to WT 265x61.5 chords (t_w = 13.1 mm).

L = 4 m

T_f = 630 kN

The material used is G40.21 300W steel (F_y = 300 MPa, F_u = 450 MPa) (FYLD and FU)
Calculations

Gross area is used for welded connections.

\[ T_r = \max \left\{ \phi AF_y = 0.9 \times 300 \times A = 270A, \phi_u AF_u = 0.75 \times 450 \times A = 338A \right\} \]

\[ T_r \geq T_f, \text{ so solve for } A: \]

\[ A = \frac{630 \times (10)^3}{270} = 2,333 \text{ mm}^2 \]

Select a pair of angles with at least this gross area: try a 2-76x64x9.5, with long legs back-to-back:

\[ A = 2,480 \text{ mm}^2 \]
\[ r_{\min} = 13.3 \text{ mm} \]

Calculate the effective net area due to shear lag. The average weld length is taken as \((120 \text{ mm} + 250 \text{ mm})/2 = 185 \text{ mm}\).

The long leg does not have a reduction in area shear lag, thus:

\[ A_{n2} = 1.00 \times (76 - 9.5) \times 9.5 = 632 \text{ mm}^2 \]

The outstanding (short) leg has an eccentricity of half the leg length, or \(64/2 = 32 \text{ mm}\).

\[ A_{n3} = \left(1 - \frac{32}{250}\right) \times 64 \times 9.5 = 530 \text{ mm}^2 \]

The total net area for the pair of angles for the rupture limit state is:

\[ A_{ne} = 632 + 530 = 1,162 \text{ mm}^2 \]

For the pair of angles, \(A_{ne} = 2 \times 1,162 = 2,324 \text{ mm}^2\); the ratio of net section area to gross area = \(2,324 / 2,480 = 0.937 (\text{NSF})\).

Checking the yielding limit state:

\[ T_r = 0.90 \times 2,480 \times 300 = 670 \text{ kN} \]

Checking the rupture limit state:

\[ T_r = 0.75 \times 2,324 \times 450 = 784 \text{ kN} \]

Yielding governs, and the critical ratio is: \(630/670 = 0.94\).

Comparison

<table>
<thead>
<tr>

</tr>
<tr>
<td>Critical Ratio</td>
<td>0.94</td>
<td>0.941</td>
<td>negligible</td>
</tr>
</tbody>
</table>

**Note:** If the member SELECT facility is used in place of a code CHECK, STAAD.Pro will actually select a 2-L 102x89x6.4 member, which has a critical ratio of 0.997 (per Cl. 13.2) and an area of 2,340 mm\(^2\), thus more economical (the NSF used for this size is 0.923).

V.CSA S16-09 - Beam Bending

Determine the uniformly factored load that the member can resist.

Reference

Problem
A W310x52 beam spans 7.3 m. Both ends of the beam are supported by columns connected standard web angle connections.
The material used is G40.21 350W steel (\(F_y = 350\) MPa) (FYLD)

Calculations
The nominal yield strength is used for the actual yield strength for a Group 2 section, per Table 3 and Table 4 of Appendix A of the reference.

Section Classification
Evaluate the slenderness effects of the beam flanges:
\[
\frac{b}{2t} = \frac{167}{2 \times 13.2} = 6.3 < \frac{170}{\sqrt{350}} = 9.1
\]
Evaluate the slenderness effects of the beam web:
\[
\frac{h}{w} = \frac{318 - 2(13.2)}{7.6} = 38.4 < \frac{1}{700} \frac{700}{\sqrt{350}} = 90.9
\]
Both the beam flanges and web are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 5.7.

Bending Capacity
Factored moment resistance is:
\[
M_r = \phi Z_x F_y = 0.90 \times 841 \times (10)^3 \times 350 = 265 \times (10)^3 \text{N} \cdot \text{mm} = 265 \text{kN} \cdot \text{m}
\]
Equate this to the bending moment due to a uniformly distributed load and solve for the load:
\[
w_f \geq \frac{8M_r}{L^2} = \frac{8 \times 265}{(7.3)^2} = 39.8 \text{ kN/m}
\]
### Comparison

**Table 508: Comparison of results**

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Reference</th>
<th>STAAD.Pro</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_r$ (kN·m)</td>
<td>265</td>
<td>265</td>
<td>none</td>
</tr>
<tr>
<td>$w_f$ (kN/m)</td>
<td>39.8</td>
<td>39.76*</td>
<td>negligible</td>
</tr>
</tbody>
</table>

**Note:** (*) STAAD.Pro does calculate the allowable uniform load on the beam. Instead, this is done by applying a uniform load incrementally until the critical ratio is ≈ 1.0. The, this uniform load is divided by the resulting critical ratio to normalize the distributed load capacity of the beam. Thus, $39.8/1.001 = 39.67$ kN/m

---

V.CSA S16-09 - Beam Shear Capacity

Reference

Problem
The W530x82 beam has a maximum shear force, \( v = 540 \text{ kN} \) due to factored loads.
\( L = 11.0 \text{ m} \)

The material used is G40.21 350W steel (\( F_y = 350 \text{ MPa} \)) (FYLD)

Calculations
Evaluate the slenderness effects of the beam web:
\[
\frac{h}{w} = \frac{528 - 2(13.3)}{9.5} = 52.8 < \frac{439}{5.34} \frac{F_y}{F_y} = 439 \sqrt{\frac{5.34}{350}} = 54.2
\]

Therefore the shear capacity is calculated as:
\[
V_r = \phi \times A_w \times F_y = 0.9 \times 528 \times 9.5 \times 350 = 1,043 \text{ kN}
\]

Calculate Equivalent Concentrated Load
The given end moments and assumed distributed loads (which was determined to given an equivalent mid-span moment of the given example) do not result in a shear force of 540 kN. Therefore, an additional concentrated load is added near the first support.
\[
R_1 = \frac{w_f L}{2} + \frac{M_1 - M_2}{L} = \frac{40.17 \times 11.0}{2} + \frac{540 - 185}{11.0} = 253.2 \text{ kN}
\]

\[
P = 540 \text{ kN} \times 253.2 \text{ kN} = 287 \text{ kN}
\]

The STAAD.Pro will have this load applied at 1 mm away from the left support.

**Verification Examples**

**V.09 Steel Design**

**STAAD.Pro 3677 User Manual**
**Verification Examples**

V.09 Steel Design
V.CSA S16-09 - Select a Beam

Select a wide-flange shape for the given beam span.

**Reference**

**Problem**

A beam must be selected to span 11.0 m. The end moment of the span are:

\[ M_1 = -540 \text{ kN m} \]
\[ M_2 = -185 \text{ kN m} \]

And the maximum moment in the span is:

\[ M_3 = 256 \text{ kN m} \]

The beam is braced at 2.5 m from the center of each supporting column (thus \( L_b = 6.0 \text{ m} \)) (LT 6.0).

The material used is G40.21 350W steel \( (F_y = 350 \text{ MPa}) \) (FYLD)

**Calculations**

Assume a Class 2 section:

\[ M_r = \phi M_p = \phi Z_x F_y \]

Thus,

\[ Z_x \geq \frac{540(10)^6}{0.9 \times 350} = 1,714 \times (10)^3 \text{ mm}^3 \]

Try a W460x82:

\[ Z_x = 1,830\times(10)^3 \text{ mm}^3, \text{ tf} = 16.0 \text{ mm}, \text{ bf} = 191.0 \text{ mm}, \text{ tw} = 9.9 \text{ mm}, \text{ D} = 460.0 \text{ mm} \]

Evaluate the slenderness effects of the beam flanges:

\[ \frac{b}{2t} = \frac{191}{2 \times 16.0} = 5.7 < \frac{170}{\sqrt{350}} = 9.1 \]

Evaluate the slenderness effects of the beam web:

\[ \frac{h}{w} = \frac{460 - 2(16.0)}{9.9} = 43.2 < \frac{1,700}{\sqrt{350}} = 90.9 \]

The assumptions are valid and this beam is sufficient to support the given moments.

\[ M_r = 0.9\times1,830\times(10)^3\times350 \times [(10)^6] = 576.5 \text{ kN m} \]
Ratio = \frac{540}{576.5} = 0.937

**Notes:**

*The reference also tries a W530x82, which is stiffer for the same weight. STAAD.Pro selects the shallower beam.

** The reference does not calculate the resisting moment capacity nor the critical ratio for either section size, but they are evaluated here for completeness.

**STAAD.Pro Input File**

The file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\Canada\S16 2009\CSA S16-09 - Select a Beam.STD is typically installed with the program.

In order to model this beam in STAAD.Pro, we need to determine the distributed load which would result in the same mid-span moment on a beam with the given end moments. From the AISC Steel Construction Manual, p 3-222:

\[ M₃ = \frac{w_f L^2}{8} - \frac{(M₁ + M₂)}{2} + \frac{(M₁ - M₂)^2}{2w_f L^2} \]

\[ 256 = \frac{w_f (11.0)^2}{8} - \frac{(540 + 185)^2}{2} + \frac{(540 - 185)^2}{2w_f (11.0)^2} \]

Solving this yields \( w_f = 40.033 \text{ kN/m} \)

V.CSA S16-09 - Shear Capacity Combined Stresses

Reference

Problem
The W250x73 column has the following concentrated loads

\[ C_f = 900 \text{ kN} \]

And a uniform moment of:

\[ M_{fs} = 180 \text{ kN m} \]

The material used is G40.21 350W steel \( (F_y = 350 \text{ MPa}) \) (FYLD). The beam is braced against lateral-torsional buckling only at the ends (LAT 0, default)
**Calculations**

**Axial Capacity**

Determine the buckling load of the column:

\[
\left( \frac{KL}{r} \right)_x = \frac{1.06 (3, 600)}{110} = 32.7
\]

\[
\left( \frac{KL}{r} \right)_y = \frac{1.06 (3, 600)}{64.6} = 55.7
\]

The largest slenderness ratio controls:

\[
F_{ex} = \frac{n^2 E}{KL} \left( \frac{55.7}{x} \right)^2 = 635.6 \text{ kN}
\]

\[
\lambda = \sqrt{\frac{F_y}{F_{ey}}} = \sqrt{\frac{350}{635.6}} = 0.742
\]

\[
C_r = \phi A F_y \left( 1 + \lambda^{2n} \right)^{-1/n} = 0.90 \times 9, 280 \times 350 \left[ 1 + 0.742 \left( 2 \times 1.34 \right) \right]^{-1/1.34} = 2, 216 \times (10)^6 \text{ N} = 2, 216 \text{ kN}
\]

**Moment Modifier**

Uniform moment:

\[
\omega_1 = 1.0
\]

Calculate the elastic buckling load for the bending axis:

\[
C_e = \frac{\pi^2 \times 200, 000 \times 113 \times 10^6}{(1.0 \times 3, 600)^2} = 17, 211 \text{ kN}
\]

\[
U_{1x} = \frac{1.0}{1 - \frac{900}{17, 211}} = 1.06
\]

**Bending Capacity**

\[
\omega_2 = 1.0
\]

\[
EI_y GJ = 200, 000 \times 38.8 \times 76.92 \times 575 = 343.2 \times 10^{21} \text{ MPa}^2 \text{ mm}^8
\]

\[
\left( \frac{nE}{L} \right)^2 I_y C_w = \left( \frac{\pi \times 200, 000}{3, 600} \right)^2 38.8 \times 553 = 653.6 \times 10^{21} \text{ MPa}^2 \cdot \text{ mm}^8
\]

\[
M_u = \frac{\omega_2 n^2}{L} \sqrt{EI_y GJ + \left( \frac{nE}{L} \right)^2 I_y C_w} = \frac{1.0 \times \pi \times 3, 600}{3, 600} \sqrt{343.2 \times 10^{21} + 653.6 \times 10^{21}} = 871 \times 10^6 \text{ N mm} = 871 \text{ kN mm}
\]

Plastic moment capacity:

\[
M_p = Z_x F_y = 985 \times 10^3 \times 350 = 345 \times 10^6 \text{ N mm} = 345 \text{ kN m}
\]

\[
M_u = 871 \text{ kN mm} > 0.67 \times M_p = 0.67 \times 345 = 231 \text{ kN m}
\]

Therefore, the moment capacity is calculated as:

\[
M_r = 1.15 \phi M_p \left( 1 - \frac{0.28 M_p}{M_u} \right) = 1.15 \times 0.9 \times 345 \left( 1 - \frac{0.28 \times 345}{871} \right) = 317 \text{ kN m}
\]
Check the capacity based on the strength cross-section:

\[ M_{rx} = 0.9 \times 985 \times 10^3 \times 350 = 310 \text{ kN} \cdot \text{m} \]

This governs capacity.

**Combined Stress Ratio**

\[ \frac{900}{2.216} + \frac{0.85 \times 1.06 \times 180}{310} = 0.406 + 0.523 = 0.929 < 1.0 \]

**Comparison**

**Table 511: Verification Problem comparison**

</table>

**Note:** Both the reference and hand calculations agree with the STAAD.Pro results that the section is adequate. The reference however neglects to account for section capacity checks, which control in this case.

**STAAD.Pro Input File**

The file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\Canada\S16 2009\CSA S16-09 - Shear Capacity Combined Stresses.STD is typically installed with the program.

V.CSA S16-09 - Short Column Compression

Determine the factored compressive resistance of a short column.

Reference

Problem
A W250x73 section is used for a pedestal with a height of 1.1 m.
The material used is G40.21 350W steel ($F_y = 350$ MPa) (FYLD)

Calculations
The nominal yield strength is used for the actual yield strength for a Group 2 section, per Table 3 and Table 4 of Appendix A of the reference.
Local Element Buckling

Evaluate the slenderness effects of the column web:

\[
\frac{h}{w} = \frac{225}{8.6} = 26.2 < \frac{670}{\sqrt{350}} = 35.8
\]

Evaluate the slenderness effects of the column flanges:

\[
\frac{b}{2r} = \frac{254}{2 \times 14.2} = 8.9 < \frac{200}{\sqrt{350}} = 10.7
\]

Both the column web and flanges are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 4.21.

Column Capacity

Assume \( K = 1.0, \)

\[
\frac{L}{r_x} = \frac{1.10}{110} = 10
\]

\[
\frac{L}{r_y} = \frac{1.10}{64.6} = 17
\]

The largest slenderness ratio controls, thus the slenderness factor for buckling about the minor axis:

\[
\lambda = \left(\frac{KL}{r}\right)_{\text{max}} \sqrt{\frac{F_y}{n^2E}} = \frac{17\sqrt{\frac{350}{n^2200,000}}}{n} = 0.227
\]

When \( n = 1.34 \) (Group 2 W shape),

\[
C_r = \phi AF_y (1 + \lambda^{2n})^{-1/n} = 0.90 \times 9, 280 \times 350 \left[1 + 0.227^{(2 \times 1.34)}\right]^{-1/1.34} = 2.883 \times (10)^6 \text{ N} = 2, 883 \text{ kN}
\]

STAAD SPACE
V.CSA S16-09 - Slender Column Compression

Determine the factored compressive resistance of a slender column.

Reference

Problem
A W250x73 section is used for a pedestal with a height of 11.0 m.
The material used is G40.21 350W steel ($F_y = 350$ MPa) (FYLD)

Calculations
The nominal yield strength is used for the actual yield strength for a Group 2 section, per Table 3 and Table 4 of Appendix A of the reference.
Local Element Buckling

Evaluate the slenderness effects of the column web:

\[ \frac{h}{w} = \frac{225}{8.8} = 26.2 < \frac{670}{\sqrt{350}} = 35.8 \]

Evaluate the slenderness effects of the column flanges:

\[ \frac{b}{2t} = \frac{254}{2 \times 14.2} = 8.9 < \frac{200}{\sqrt{350}} = 10.7 \]

Both the column web and flanges are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 4.21.

Column Capacity

Assume \( K = 1.0 \),

\[ \frac{L}{r_x} = \frac{11,000}{110} = 100 \]

\[ \frac{L}{r_y} = \frac{11,000}{64.6} = 170 \]

The largest slenderness ration controls, thus the slenderness factor for buckling about the minor axis:

\[ F_e = \frac{\pi^2 \times 200,000}{(1.0 \times 170)^2} = 68.3 \text{ kN} \]

\[ \lambda = \sqrt{\frac{F_y}{F_e}} = \sqrt{\frac{350}{68.3}} = 2.26 \]

When \( n = 1.34 \) (Group 2 W shape),

\[ C_r = \phi A F_y \left(1 + \lambda^2 n\right)^{-1/n} = 0.90 \times 9, 280 \times 350 \left[1 + 2.26^{(2 \times 1.34)}\right]^{-1/1.34} = 0.529 \times (10)^6 \text{ N} = 529 \text{ kN} \]

**STAAD.Pro**

**User Manual**
V.CSA S16-09 - Wide Flange Capacity Combined Stresses

Check the capacity of a wide-flange column under combined stresses.

Reference

Problem

The W250x73 column has the following concentrated loads applied at the top of the column:

\[ C_f = 900 \text{ kN} \]

\[ M_{fx} = 180 \text{ kN m} \]
The material used is G40.21 350W steel ($F_y = 350 \text{ MPa}$) (FYLD). The column is assumed to be braced laterally against lateral-torsional buckling (LAT 1).

$L = 3.6 \text{ m}$

Calculations

Local Element Buckling

Evaluate the slenderness effects of the column web:

$$\frac{h}{w} = \frac{225}{8.6} = 26.2 < \frac{670}{\sqrt{350}} = 35.8$$

Evaluate the slenderness effects of the column flanges:

$$\frac{b}{2t} = \frac{254}{2 \times 14.2} = 8.9 < \frac{200}{\sqrt{350}} = 10.7$$

Both the column web and flanges are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 4.21.

Axial Capacity

Determine the buckling load of the column, assuming that weak axis bucking will not control due to bracing:

$$\frac{(KL/r)_x}{1.0(600)} = \frac{1.0(600)}{116} = 32.7$$

The largest slenderness ratio controls:

$$F_{ex} = \frac{n^2 E}{(KL/r)_x} = \frac{n^2 (200,000)}{(32.7)^2} = 1,847 \text{ kN}$$

$$\lambda = \sqrt{\frac{F_{ex}}{F_{ey}}} = \sqrt{\frac{350}{1,847}} = 0.435$$

$$C_r = \phi A F_y (1 + \lambda^{2n})^{-1/n} = 0.90 \times 9, 280 \times 350 [1 + 0.435^{(2 \times 1.34)}]^{-1/1.34} = 2,716 \times (10)^6 \text{ N} = 2,716 \text{ kN}$$

Moment Modifier

$$\kappa = -0/180 = 0$$

$$\omega_1 = 0.6 - 0.4 \kappa = 0.6 \leq 1.0$$

Calculate the elastic buckling load for the bending axis:

$$C_e = \frac{n^2 	imes 200,000 \times 113 \times 10^6}{(1.0 \times 3,600)^2} = 17,211 \text{ kN}$$

$$U_{1x} = \frac{0.6}{1 - \left(\frac{900}{17,210}\right)} = 0.633$$

Bending Capacity

From a previous example, the W250x73 is a Class 2 section. It is laterally supported along its length, thus:
\[ M_{1x} = 0.9 \times 985 \times 10^3 \times 350 = 310 \text{ kN m} \]

**Combined Stress Ratio**

\[ \frac{900}{2} \times \frac{716}{310} + \frac{0.85 \times 0.633 \times 180}{310} = 0.331 + 0.312 = 0.644 < 1.0 \]

This is the check for overall member strength. However, there is another case that actually controls in this instance: checking for cross sectional strength.

\[ C_r = 0.9 \times 9,280 \times 350 = 2,923 \text{ kN} \]

\[ U_{1x} = 1.0 \]

\[ \frac{900}{2} \times \frac{923}{310} + \frac{0.85 \times 1.0 \times 180}{310} = 0.308 + 0.494 = 0.801 < 1.0 \]

**Comparison**

**Note:** Both the reference and hand calculations agree with the STAAD.Pro results that the section is adequate. The reference however neglects to account for section capacity checks, which control in this case.

V. CAN/CSA S16-14

The following are several verification examples for reference purposes. Since the S16-14 code is similar in many respects to the previous edition of the code (CAN/CSA S16-09), the solved examples of the 1994 edition of the CISC Handbook have been used as reference material for these examples.

V. CSA S16-14 - Axial Tension

Design of a double-angle member subject to tension load.

Reference

Problem
Design a tension diagonal in an all-welded truss (SNU 0 for welded). Attached to WT 265x61.5 chords (t_w = 13.1 mm).

\[ L = 4 \, \text{m} \]
\[ T_f = 630 \, \text{kN} \]

The material used is G40.21 300W steel \( (F_y = 300 \, \text{MPa}, F_u = 450 \, \text{MPa}) \) \( (\text{FYLD and FU}) \)

Calculations
Gross area is used for welded connections.

\[ T_r = \max\left\{ \phi_A F_y = 0.9 \times 300 \times A = 270\,A \right\}
\[ \phi_u A F_u = 0.75 \times 450 \times A = 338\,A \]
\[ T_r \geq T_f, \text{ so solve for } A: \]
\[ A = \frac{630 \times (10)^3}{270} = 2,333 \text{ mm}^2 \]

Select a pair of angles with at least this gross area: try a 2-76x64x9.5, with long legs back-to-back:
\[ A = 2,480 \text{ mm}^2 \]
\[ r_{\min} = 13.3 \text{ mm} \]

Calculate the effective net area due to shear lag. The average weld length is taken as \((120 \text{ mm} + 250 \text{ mm})/2 = 185 \text{ mm}\).

The long leg does not have a reduction in area shear lag, thus:
\[ A_{n2} = 1.00 \times (76 - 9.5) \times 9.5 = 632 \text{ mm}^2 \]

The outstanding (short) leg has an eccentricity of half the leg length, or \(64/2 = 32 \text{ mm}\).
\[ A_{n3} = \left(1 - \frac{32}{250}\right) \times 64 \times 9.5 = 530 \text{ mm}^2 \]

The total net area for the pair of angles for the rupture limit state is:
\[ A_{ne} = 632 + 530 = 1,162 \text{ mm}^2 \]

For the pair of angles, \(A_{ne} = 2 \times 1,1162 = 2,324 \text{ mm}^2\); the ratio of net section area to gross area = \(2,324 / 2,480 = 0.937 \text{ (NSF)}\).

Checking the yielding limit state:
\[ T_r = 0.90 \times 2,480 \times 300 = 670 \text{ kN} \]

Checking the rupture limit state:
\[ T_r = 0.75 \times 2,324 \times 450 = 784 \text{ kN} \]

Yielding governs, and the critical ratio is: \(630/670 = 0.94\).

### Comparison

--- END OF DESIGN OUTPUT OF MEMBER 1 ---

--- Page No. ---
V. CSA S16-14 - Beam Bending

Determine the uniformly factored load that the member can resist.

Reference

Problem
A W310x52 beam spans 7.3 m. Both ends of the beam are supported by columns connected standard web angle connections.

The material used is G40.21 350W steel ($F_y = 350 \text{ MPa}$) (FYLD)

Calculations

The nominal yield strength is used for the actual yield strength for a Group 2 section, per Table 3 and Table 4 of Appendix A of the reference.

Section Classification

Evaluate the slenderness effects of the beam flanges:

$$b = \frac{167}{2 \times 13.2} = 6.3 < \frac{170}{\sqrt{350}} = 9.1$$

Evaluate the slenderness effects of the beam web:

$$h = \frac{318 - 2(13.2)}{7.6} = 38.4 < \frac{1,700}{\sqrt{350}} = 90.9$$

Both the beam flanges and web are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 5.7.

Bending Capacity

Factored moment resistance is:

$$M_r = \phi Z_x F_y = 0.90 \times 841 \times (10)^3 \times 350 = 265 \times (10)^3 \text{ N} \cdot \text{mm} = 265 \text{ kN} \cdot \text{m}$$

Equate this to the bending moment due to a uniformly distributed load and solve for the load:

$$M_r \geq \frac{w_f L^2}{8}$$

$$w_f = \frac{8M_r}{L^2} = \frac{8 \times 265}{(7.3)^2} = 39.8 \text{ kN/m}$$
Comparison

Table 516: Comparison of results

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Reference</th>
<th>STAAD.Pro</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_r$ (kN·m)</td>
<td>265</td>
<td>265</td>
<td>none</td>
</tr>
<tr>
<td>$w_f$ (kN/m)</td>
<td>39.8</td>
<td>39.76*</td>
<td>negligible</td>
</tr>
</tbody>
</table>

**Note:** (*) STAAD.Pro does calculate the allowable uniform load on the beam. Instead, this is done by applying a uniform load incrementally until the critical ratio is $\approx 1.0$. The, this uniform load is divided by the resulting critical ratio to normalize the distributed load capacity of the beam. Thus, $\frac{39.8}{1.001} = 39.67$ kN/m

V. CSA S16-14 - Beam Shear Capacity

Reference

Problem
The W530x82 beam has a maximum shear force, \( v = 540 \text{ kN} \) due to factored loads.

\[ L = 11.0 \text{ m} \]

The material used is G40.21 350W steel (\( F_y = 350 \text{ MPa} \)) (FYLD)

Calculations
Evaluate the slenderness effects of the beam web:

\[
\frac{h}{w} = \frac{528 - 2(13.3)}{9.5} = 52.8 < 439 \sqrt{\frac{F_y}{F_y}} = 439 \sqrt{\frac{534}{350}} = 54.2
\]

Therefore the shear capacity is calculated as:

\[
V_r = \phi A_w \times F_y = 0.9 \times 528 \times 9.5 \times 350 = 1,043 \text{ kN}
\]

Calculate Equivalent Concentrated Load
The given end moments and assumed distributed loads (which was determined to given an equivalent mid-span moment of the given example) do not result in a shear force of 540 kN. Therefore, an additional concentrated load is added near the first support.

\[
R_1 = \frac{w_f L}{2} + \frac{M_1 - M_2}{L} = \frac{40.17 \times 11.0}{2} + \frac{540 - 185}{11.0} = 253.2 \text{ kN}
\]

\[
P = 540 \text{ kN} - 253.2 \text{ kN} = 287 \text{ kN}
\]

The STAAD.Pro will have this load applied at 1 mm away from the left support.

V. CSA S16-14 - Select a Beam

Select a wide-flange shape for the given beam span.

Reference

Problem
A beam must be selected to span 11.0 m. The end moment of the span are:

\[ M_1 = -540 \text{ kN\cdot m} \]
\[ M_2 = -185 \text{ kN\cdot m} \]

And the maximum moment in the span is:

\[ M_3 = 256 \text{ kN\cdot m} \]

The beam is braced at 2.5 m from the center of each supporting column (thus \( L_b = 6.0 \text{ m} \)) (LT 6.0). The material used is G40.21 350W steel (\( F_y = 350 \text{ MPa} \)) (FYLD)

Calculations
Assume a Class 2 section:

\[ M_x = \phi M_p = \phi Z_x F_y \]

Thus,

\[ Z_x \geq \frac{540(10)^6}{0.9 \times 350} = 1, 714 \times (10)^3 \text{ mm}^3 \]

Try a W460x82:

\[ Z_x = 1,830(10)^3 \text{ mm}^3, tf = 16.0 \text{ mm}, bf = 191.0 \text{ mm}, tw = 9.9 \text{ mm}, D = 460.0 \text{ mm} \]

Evaluate the slenderness effects of the beam flanges:

\[ \frac{b}{2t} = \frac{191}{2 \times 16.0} = 5.7 < \frac{170}{\sqrt{350}} = 9.1 \]
Evaluate the slenderness effects of the beam web:

\[
\frac{h}{w} = \frac{460 - 2(16.0)}{9.9} = 43.2 < \frac{1.700}{\sqrt{350}} = 90.9
\]

The assumptions are valid and this beam is sufficient to support the given moments.

\[
M_r = 0.9 \times 1.830 \times 10^3 \times 350 \left[(10)^6\right] = 576.5 \text{ kN·m}
\]

Ratio = \(\frac{540}{576.5} = 0.937\)

**Comparison**

<td>0.937 **</td>
<td>0.937</td>
<td>none</td>
</tr>
</tbody>
</table>

**Notes:**

*The reference also tries a W530x82, which is stiffer for the same weight. STAAD.Pro selects the shallower beam.

** The reference does not calculate the resisting moment capacity nor the critical ratio for either section size, but they are evaluated here for completeness.

**STAAD Input**

The file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\Canada\S16 2014\CSA S16-14 - Select a Beam.STD is typically installed with the program.

In order to model this beam in STAAD.Pro, we need to determine the distributed load which would result in the same mid-span moment on a beam with the given end moments. From the AISC Steel Construction Manual, p 3-222:

\[
M_3 = \frac{w_f L^2}{8} - \frac{(M_1 + M_2)^2}{2} + \frac{(M_1 - M_2)^2}{2w_f L^2}
\]

\[
256 = \frac{w_f (11.0)^2}{8} - \frac{(540 + 185)^2}{2} + \frac{(540 - 185)^2}{2w_f (11.0)^2}
\]

Solving this yields \(w_f = 40.033\) kN/m

STAAD SPACE
### V. CSA S16-14 - Shear Capacity Combined Stresses

**Reference**

Problem
The W250x73 column has the following concentrated loads
\[ C_f = 900 \text{ kN} \]
And a uniform moment of:
\[ M_{fx} = 180 \text{ kN m} \]
The material used is G40.21 350W steel \( (F_y = 350 \text{ MPa}) \) \( \text{(FYLD)} \). The beam is braced against lateral-torsional buckling only at the ends \( \text{(LAT \ 0, default)} \).

Calculations

Axial Capacity
Determine the buckling load of the column:
\[
\left( \frac{KL}{r} \right)_x = \frac{1.0(3,600)}{110} = 32.7
\]
\[
\left( \frac{KL}{r} \right)_y = \frac{1.0(3,600)}{64.6} = 55.7
\]
The largest slenderness ratio controls:
\[
F_{ex} = \frac{n^2E}{(KL/r)_x^2} = \frac{n^2(200,000)}{(55.7)^2} = 635.6 \text{ kN}
\]
\[
\lambda = \sqrt{\frac{F_y}{F_{ey}}} = \sqrt{\frac{350}{635.6}} = 0.742
\]
\[
C_r = \phi AF_y (1 + \lambda^{2n})^{-1/n} = 0.90 \times 9, 280 \times 350[1 + 0.742^{(2 \times 1.34)}]^{-1/1.34} = 2, 216 \times (10)^6 \text{ N} = 2, 216 \text{ kN}
\]

Moment Modifier
Uniform moment:
\[
\omega_1 = 1.0
\]
Calculate the elastic buckling load for the bending axis:
\[
C_e = \frac{n^2 \times 200,000 \times 113 \times 10^6}{(1.0 \times 3,600)^2} = 17, 211 \text{ kN}
\]
\[
U_{1x} = \frac{1.0}{1 - \frac{900}{17,211}} = 1.06
\]

Bending Capacity
\[
\omega_2 = 1.0
\]
\[
EI_yGJ = 200,000 \times 38.8 \times 76.92 \times 575 = 343.2 \times 10^{21} \text{ MPa}^2 \text{ mm}^8
\]
\[
\left( \frac{nE}{L} \right)^2 I_y C_w = \left( \frac{n \times 200,000}{3,600} \right)^2 38.8 \times 553 = 653.6 \times 10^{21} \text{ MPa}^2 \cdot \text{ mm}^8
\]
\[ M_u = \frac{\omega^2}{L^2} EI_y GJ + \left(\frac{nK}{L}\right)^2 I_y C_w = \frac{1.0 \times 934.2 \times 10^{21} + 653.6 \times 10^{21}}{3,600^2} = 871 \times 10^6 \text{ N mm} = 871 \text{ kN m} \]

Plastic moment capacity:
\[ M_p = Z_x F_y = 985 \times 10^3 \times 350 = 345 \times 10^6 \text{ N mm} = 345 \text{ kN m} \]
\[ M_u = 871 \text{ kN m} > 0.67 \times M_p = 0.67 \times 345 = 231 \text{ kN m} \]

Therefore, the moment capacity is calculated as:
\[ M_r = 1.15 \phi M_p \left(1 - \frac{0.28 M_p}{M_u}\right) = 1.15 \times 0.9 \times 345 \left(1 - \frac{0.28 \times 345}{871}\right) = 317 \text{ kN m} \]

Check the capacity based on the strength cross-section:
\[ M_{rx} = 0.9 \times 985 \times 10^3 \times 350 = 310 \text{ kN m} \]

This governs capacity.

**Combined Stress Ratio**
\[
\frac{900}{2,216 \times 0.85 \times 1.06 \times 180} = 0.406 + 0.523 = 0.929 < 1.0
\]

V. CSA S16-14 - Short Column Compression

Determine the factored compressive resistance of a short column.

Reference
Example 4.1

Problem
A W250x73 section is used for a pedestal with a height of 1.1 m.
The material used is G40.21 350W steel ($F_y = 350 \text{ MPa}$) (FYLD)

Calculations
The nominal yield strength is used for the actual yield strength for a Group 2 section, per Table 3 and Table 4 of Appendix A of the reference.

Local Element Buckling
Evaluate the slenderness effects of the column web:

$$\frac{b}{w} = \frac{225}{8.6} = 26.2 < \frac{670}{\sqrt{350}} = 35.8$$

Evaluate the slenderness effects of the column flanges:

$$\frac{b}{2t} = \frac{254}{2 \times 14.2} = 8.9 < \frac{200}{\sqrt{350}} = 10.7$$

Both the column web and flanges are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 4.21.

Column Capacity
Assume $K = 1.0$,

$$\frac{L}{r_x} = \frac{1,100}{110} = 10$$

$$\frac{L}{r_y} = \frac{1,100}{64.6} = 17$$

The largest slenderness ratio controls, thus the slenderness factor for buckling about the minor axis:

$$\lambda = \left(\frac{KL}{r}\right)_{\text{max}} \sqrt{\frac{F_y}{\pi^2 E}} = 17 \sqrt{\frac{350}{\pi^2 200,000}} = 0.227$$

When $n = 1.34$ (Group 2 W shape),

$$C_r = \phi A F_y (1 + \lambda^{2n})^{-1/n} = 0.90 \times 9, 280 \times 350 \left[1 + 0.227^{(2 \times 1.34)}\right]^{-1/1.34} = 2.883 \times (10)^6 \text{ N} = 2, 883 \text{ kN}$$

V. CSA S16-14 - Slender Column Compression

Determine the factored compressive resistance of a slender column.

Reference

Problem
A W250x73 section is used for a pedestal with a height of 11.0 m. The material used is G40.21 350W steel \((F_y = 350 \text{ MPa})\) (FYLD)

Calculations
The nominal yield strength is used for the actual yield strength for a Group 2 section, per Table 3 and Table 4 of Appendix A of the reference.

Local Element Buckling
Evaluate the slenderness effects of the column web:
\[
\frac{h}{w} = \frac{225}{8.6} = 26.2 < \frac{670}{\sqrt{350}} = 35.8
\]
Evaluate the slenderness effects of the column flanges:
\[
\frac{b}{2t} = \frac{254}{2 \times 14.2} = 8.9 < \frac{200}{\sqrt{350}} = 10.7
\]
Both the column web and flanges are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 4.21.

Column Capacity
Assume \(K = 1.0\),
\[
\frac{L}{r_x} = \frac{11,000}{110} = 100
\]
\[ \frac{L}{r_y} = \frac{11,000}{64.6} = 170 \]

The largest slenderness ration controls, thus the slenderness factor for buckling about the minor axis:

\[ F_e = \frac{\pi^2 \times 200,000}{(1.0 \times 170)^2} = 68.3 \text{kN} \]

\[ \lambda = \sqrt{\frac{F_y}{F_e}} = \sqrt{\frac{350}{68.3}} = 2.26 \]

When \( n = 1.34 \) (Group 2 W shape),

\[ C_r = \phi A F_y (1 + \lambda^{2n})^{-1/n} = 0.90 \times 9, 280 \times 350 \left[1 + 2.26^{(2 \times 1.34)}\right]^{-1/1.34} = 0.529 \times (10)^6 \text{N} = 529 \text{kN} \]

******** END OF THE STAAD.Pro RUN ********
V. CSA S16-14 - Wide Flange Capacity Combined Stresses

Check the capacity of a wide-flange column under combined stresses.

Reference

Problem
The W250x73 column has the following concentrated loads applied at the top of the column:

\[ C_f = 900 \text{ kN} \]
\[ M_{fx} = 180 \text{ kN} \cdot \text{m} \]

The material used is G40.21 350W steel \( (F_y = 350 \text{ MPa}) \) (FYLD). The column is assumed to be braced laterally against lateral-torsional buckling (LAT 1).

\[ L = 3.6 \text{ m} \]

Calculations

Local Element Buckling

Evaluate the slenderness effects of the column web:

\[ \frac{h}{w} = \frac{225}{8.6} = 26.2 < \frac{670}{350} = 35.8 \]

Evaluate the slenderness effects of the column flanges:

\[ \frac{b}{2t} = \frac{254}{2 \times 14.2} = 8.9 < \frac{200}{\sqrt{350}} = 10.7 \]

Both the column web and flanges are less than the local buckling limit, so the capacity of the column is evaluated using Eq. 4.21.
Axial Capacity

Determine the buckling load of the column, assuming that weak axis bucking will not control due to bracing:

\[
\left( KL \right)_x = \frac{1.0 \times 3,600}{110} = 32.7
\]

The largest slenderness ratio controls:

\[
F_{ex} = \frac{n^2 E}{KL_x^2} = \frac{n^2 (200,000)}{(32.7)^2} = 1,847 \text{ kN}
\]

\[
\lambda = \sqrt{\frac{F_y}{F_{ey}}} = \sqrt{\frac{350}{1,847}} = 0.435
\]

\[
C_r = \phi A F_y \left( 1 + \lambda^{2n} \right)^{-1/n} = 0.90 \times 9,280 \times 350 \left[ 1 + 0.435 \left( 2 \times 1.34 \right) \right]^{-1/1.34} = 2,716 \times (10)^6 \text{ N} = 2,716 \text{ kN}
\]

Moment Modifier

\[
\kappa = -0/180 = 0
\]

\[
\omega_1 = 0.6 - 0.4\kappa = 0.6 \leq 1.0
\]

Calculate the elastic buckling load for the bending axis:

\[
C_e = \frac{n^2 \times 200,000 \times 113 \times 10^6}{(1.0 \times 3,600)^2} = 17,211 \text{ kN}
\]

\[
U_{1x} = \frac{0.6}{1 - \left( \frac{900}{17,920} \right)} = 0.633
\]

Bending Capacity

From a previous example, the W250x73 is a Class 2 section. It is laterally supported along its length, thus:

\[
M_{rx} = 0.9 \times 985 \times 10^3 \times 350 = 310 \text{ kN} \cdot \text{m}
\]

Combined Stress Ratio

\[
\frac{900}{2,716} + \frac{0.85 \times 0.633 \times 180}{310} = 0.331 + 0.312 = 0.644 < 1.0
\]

This is the check for overall member strength. However, there is another case that actually controls in this instance: checking for cross sectional strength.

\[
C_r = 0.9 \times 9,280 \times 350 = 2,923 \text{ kN}
\]

\[
U_{1x} = 1.0
\]

\[
\frac{900}{2,923} + \frac{0.85 \times 1.0 \times 180}{310} = 0.308 + 0.494 = 0.801 < 1.0
\]

V.IS801

V.IS 801-Beam with axial and major axis bending

Verification example for a cold-formed beam subject to axial compression and bending moment according to IS801.

Details

Verifies the calculations for an IS 60CU40x4 (Channel without lips) beam that is 2 m long and subject to axial compression and major axis bending moment. This example checks for compression, shear, bending and compression and bending interaction as per IS 801.

Material properties:

\[
\begin{align*}
E &= 2,074,000 \text{ kgf/cm}^2 = 203,400 \text{ MPa} \\
F_{y1} &= 350.0 \text{ MPa} = 3,569 \text{ kgf/cm}^2 \\
F_u &= 450 \text{ MPa} \\
G &= 795,000 \text{ kgf/cm}^2 = 77,963 \text{ MPa}
\end{align*}
\]

Design forces:

\[
\begin{align*}
P &= 0.5 \text{ kN} \\
M_z &= 0.748 \text{ kN m} \\
V_y &= 1.874 \text{ kN}
\end{align*}
\]

Verification

Section Dimension Checks

Check for flat width ratio:

\[
\begin{align*}
w &= b \cdot (r + t) = r \cdot (0.4 + 0.6) = 3 \text{ mm} \\
w/t &= 3 / 0.4 = 7.5 < 60
\end{align*}
\]
Hence, OK (ref. cl 5.2.3(a))
\[ h_w/t = (d - 2\times t_f - 2\times \text{root radius})/t = (6 - 2\times0.4 - 2\times0.6)/0.4 = 10 < 500 \]
Hence, OK (ref. cl 5.2.3(b))
Check for web height to thickness ratio:
\[ h/t = (6 - 2\times0.4)/0.4 = 13 < 150 \]
Hence, OK (ref. cl 5.2.4(a))
Check for limiting slenderness
\[ k_{Lyr} = 1.0 \frac{200 \text{ mm}}{1.263 \text{ mm}} = 158.3 < 200 \]
Hence, OK (ref. cl 6.3.3)

**Calculation of Allowable Compressive Stress**

For calculation of axially loaded member, “Q” is an important factor. The definition and method of calculation for value of Q is provided in Clause no. 6.6.1.1 (a). Channel section without lips is a combination of stiffened & unstiffened elements.

As per clause no 6.1.1.1 of IS801, the increase of steel strength happens due to cold work of forming.

Total corner area, \( A_{corner} = 2(45.2 \text{ mm}^2) = 91.2 \text{ mm}^2 = 0.912 \text{ cm}^2 \)

Total area of flanges, \( A_{flange} = 2\times b\times t = 2(0.4)(0.4) = 3.2 \text{ cm}^2 \)

\[ C = \frac{A_{corner}}{A_{flange}} = \frac{0.931}{3.2} = 0.285 \]

Effective depth, \( h_e = h = 4 \text{ cm} \)

Therefore, effective area, \( A_e = A = 4.91 \text{ cm}^2 \)

\[ B_e = 3.69 \left( \frac{F_u}{F_y} \right) \times 0.819 \left( \frac{F_u}{F_y} \right)^2 \times 1.79 = 1.6004 \]
\[ m = 0.192 \left( \frac{F_u}{F_y} \right) \times 0.068 = 0.1789 \]

Tensile yield point of corner, \( F_{yc} = \frac{F_u \times F_y}{r} \times m = 521.0 \text{ MPa} \)

Tensile yield point of flat portions, \( F_{yt} = F_y = 350.0 \text{ MPa} \)

Average yield point of cold-forming for tension/compression members, \( F_{ya(compression)} = (C \times F_{yc}) + (1 - C) \times F_{yc} = 381.8 \text{ MPa} \)

Average yield point of cold-forming for flexural members, \( F_{ya(bending)} = (C \times F_{yc}) + (1 - C) \times F_{yc} = 398.8 \text{ MPa} \)

As per cl. 6.2 of IS 801, compressive stress:
\[ F_c = 0.6 \times F_{ya} = 0.6 \times 381.8 = 229.1 \text{ MPa} \]
\[ Q_s = \frac{F_c}{0.6 \times F_{ya}} = \frac{229.1}{229.1} = 1 \]
Verification Examples

STAAD.Pro 3755 User Manual

\[ h = d - 2(r + t) = 4 \text{ cm} \]
\[ \frac{b}{t} = 13 < \frac{1435}{\sqrt{F_c}} = 29.69 \]
\[ Q_a = \frac{A_e}{A} = 1 \]
\[ Q = Q_a 	imes Q_d = 1 \]

Allowable compression stress, \( F_{a1} \), for members braced against twisting (ref. cl 6.6.1.1)

\[ C_e = \sqrt{\frac{2\pi E}{F_{ya}}} = 102.5 \]
\[ \frac{C_e}{\sqrt{Q}} = 102.5 \]

Slenderness ratio \( KL/r = 158.3 \)

\[ F_{a1} = \frac{12}{285} Q \times F_{ya} \times \frac{3(Q \times F_{ya})}{23a^2E} \left( \frac{KL}{r} \right)^2 = 41.06 \text{ MPa} \]

Maximum allowable compressive stress (Fa2) for flexural-torsional buckling (ref. cl 6.6.1.2 of IS 801)

\[ r_0 = \sqrt{(r_x^2) + (r_y^2) + (x_0^2)} = 3.732 \text{ cm} \]
\[ \sigma_x = \pi^2 \times \frac{E}{K \times L} = 274.8 \text{ MPa} \]
\[ \beta = 1 - \left( \frac{x_0}{r_x} \right)^2 = 0.5071 \]
\[ \sigma_t = \frac{1}{A \times r_o^2} \times \frac{(G \times J) + (\pi^2 \times E \times C_w)}{(K \times L_x)^2} = 324.2 \text{ MPa} \]
\[ \sigma_{TF0} = \frac{1}{2\beta} \left[ (\sigma_{ex} + \sigma_t) \times \sqrt{(\sigma_{ex} + \sigma_t)^2 - 4\beta \times \sigma_{ex} \times \sigma_t} \right] = 174.5 \text{ MPa} \]
\[ F_{Qy} = F_y \times Q = 381.8 \text{ MPa} \]
\[ F_{a2} = 0.522 \times \sigma_{TF0} = 91.09 \text{ MPa} \]

The allowable compressive stress, \( F_a \) is the minimum of \( F_{a1} \) and \( F_{a2} \):

\[ F_a = 41.06 \text{ MPa} \]

**Calculation of Allowable Bending Stress**

As per clause number 6.1, maximum allowable stress on extreme fiber is:

\[ F = 0.6 \times F_{ya(compression)} = 0.6 \times 381.8 \text{ MPa} = 229.1 \text{ MPa} \]

As the section is channel without lips, the flanges are unstiffened. So, as per clause 6.2 we need to check allowable compressive stress on the unstiffened element.

\[ \frac{w}{T} = 7.5 < \frac{530}{\sqrt{F_{ya}}} = \frac{530}{\sqrt{3893 \text{ kgf/cm}^2}} = 8.494 \]

Also, the yield strength of steel, \( F_y > 2,230 \text{ kgf/cm}^2 \) (= 227.5 MPa).
\[ F_c = 0.6 \times F_{ya(\text{compression})} = 229.1 \text{ MPa} \]

For the major axis bending, the allowable compressive stress, \( F_{bc} \), is the minimum of \( F \) and \( F_c \)

\[ F_{bc} = 229.1 \text{ MPa} \]

Similarly, for major axis bending, the allowable tensile stress, \( F_{bt} = 0.6 \times F_{ya(\text{compression})} = 229.1 \text{ MPa} \)

Calculate the allowable bending stress for laterally unbraced beams:

Unsupported length, \( L = 2 \text{ m} \) (the UNL parameter can be used for this).

\[ S_{xc} = Z_{xx} = 8.93 \text{ cm}^3 \]

\( C_b = 1.0 \) for a member under compression and bending.

\[
\frac{L}{d} \times \frac{S_{xc}}{I_{yc}} = 14,140 > 1.8n^2E \frac{C_b}{F_{ya(\text{compression})}} = 9,464
\]

\[ F_b = 0.6n^2E \times C_b \frac{d}{L} \times \frac{I_{yc}}{S_{xc}} = 85.18 \text{ MPa} \]

Allowable bending stress in the web:

\[ F_{bw1} = \frac{36,560,000}{h^2} = 216,330 \text{ kgf/cm}^2 = 21,215 \text{ MPa} \]

Per cl. 6.4.2, \( F_{bw} \) is the minimum of \( F_{bw1} \) and \( 0.6 \times F_{ya(bending)} = 239.2 \text{ MPa} \)

\[ F_{bw} = 239.2 \text{ MPa} \]

**Calculation of Allowable Shear Stress**

Per cl. 6.4:

Clear distance between flanges = \( h = d - 2t = 52 \text{ mm} \)

\[ F_{v1} = \frac{1275 \times \sqrt{F_y}}{h/t} = 577.1042 \text{ MPa} \quad \text{(cl. 6.4.1(a))} \]

\[ F_{v2} = \frac{585000}{h/t^2} = 3.395 \text{ MPa} \quad \text{(cl. 6.4.1(b))} \]

\[ h/t = 13 < \frac{4590}{\sqrt{F_y}} = 76.8 \]

Allowable shear stress, \( F_v \) is the minimum of \( F_{v1} \) or \( 0.4 \times F_y = 140.1 \text{ MPa} \)

\[ F_v = 140.1 \text{ MPa} \]

Allowable combined bending and shear stress:

\[ \frac{h}{t} < \frac{4590}{\sqrt{F_y}}, F_{vc} = F_{vcl} = 577.1 \text{ MPa} \]

**Actual Stresses**

Compression
f_a = P/A = 0.5 kN / 4.91 mm^2 = 1.018 MPa

Bending

f_b = M / Z_{xx} = 0.748 kN m / 8.93 cm^3 = 83.76 MPa

Bending in Web

Actual bending stress in the web is calculated by interpolation of bending stress diagram:

\[
f_{bw} = f_b \times \left(1 - \frac{t}{0.5 \times d}\right) = 72.59 \text{ MPa}
\]

Shear

\[
f_v = \frac{V}{N_c(t(d - 2t)^2)} = \frac{1.874(10)^3}{(1406 - 2 \times 4)} = 9.01 \text{ MPa}
\]

Stress Ratio

Compression

f_a / F_a = 1.018 / 41.06 = 0.024

Bending

for bending compression: f_b / F_{bc} = 83.76 / 229.1 = 0.366
for bending tension: f_b / F_{bt} = 83.76 / 229.1 = 0.366
for unbraced bending: f_b / F_b = 83.76 / 85.18 = 0.983
for web bending: f_{bw} / F_{bw} = 72.59 / 239.2 = 0.303

Shear

f_v / F_v = 9.01 / 140.1 = 0.064

Combined bending and shear (ref. cl 6.4.3 of IS 801):

\[
\sqrt{\left(\frac{f_{bw}}{F_{bw1}}\right)^2 + \left(\frac{f_v}{F_{vy1}}\right)^2} = \sqrt{\left(\frac{72.59}{2121.5}\right)^2 + \left(\frac{9.01}{577.1}\right)^2} = 0.016
\]

Interaction ratio for axial and bending

As Q = 1.0, F_{a0} can be calculated using cl. 6.6.1.1(b) with L = 0:

\[
F_{a0} = \frac{12}{23} Q \times F_{ya} \cdot \frac{3(Q \times F_{ya})^2}{23a^2 E} \left(\frac{K + L}{r}\right)^2 = 182.6 \text{ MPa}
\]

\[
\frac{f_a}{F_{a0}} + \frac{f_b}{F_{b1}} = \frac{1.018}{182.6} + \frac{83.76}{229.1} = 0.371
\]

V.IS 801-Column with axial and major axis bending

Verification example for a cold-formed column subject to axial compression and bending moment according to IS801.

Details

Verifies the calculations for an IS 60CS40x4 (channel with lips) column that is 2 m long and subject to axial compression and major axis bending moment. This example checks for compression, shear, bending, and compression and bending interaction as per IS 801.

Material properties:

\[ E = 2,074,000 \text{ kgf/cm}^2 = 203,400 \text{ MPa} \]
\[ F_y = 3,569 \text{ kgf/cm}^2 = 353.0 \text{ MPa} \]
\[ F_u = 4,588 \text{ kgf/cm}^2 = 450 \text{ MPa} \]
\[ G = 795,000 \text{ kgf/cm}^2 = 77,963 \text{ MPa} \]

Design forces:

\[ P = 10 \text{ kN} \]
\[ M_z = 4.0 \text{ kN·m} \]
\[ V_y = 2 \text{ kN} \]

Verification

Section Dimension Checks

Flanges (ref. cl 5.2.3):

\[ w = 4 \times 2 \times 0.4 \times 2 \times 0.6 = 2 \]
\[ w/t = 2 / 0.4 = 5 < 60, \text{ Hence OK} \]

Web (ref. cl 5.2.4):

\[ W/t = (6 \times 2 \times 0.4 \times 2 \times 0.6) / 0.4 = 10 < 500 \text{ and} \]
\[ h/t = (6 \times 2 \times 0.4) / 0.4 = 13 < 150, \text{ Hence OK} \]

Check for limiting slenderness (ref. cl 6.3.3):

\[ K \times L_y/r_y = 1.0 \times 200 \text{ mm} / 1.453 \text{ mm} = 137.6 < 200 \]

Hence, OK
**Allowable Compression Strength**

Maximum allowable compressive stress for flexural buckling $Y$ (ref. cl 6.6.1.1 of IS 801)

Design stress, $F = 0.6 \times f_y = 2,160 \text{ kgf/cm}^2 = 211.8 \text{ MPa}$

Effective width of flange, $B_{eff}$

\[ W = 4 - 2 \times 0.4 - 2 \times 0.6 = 2 \text{ cm} \]
\[ \frac{w}{t} = 5 < \frac{1.435}{\sqrt{F}} = 30.87 \]
\[ B_{eff} = w = 2 \text{ cm} \]

Effective width of web, $B_{eff}$

\[ W/t < 30.87 \]
\[ B_{eff} = w = 10 \text{ cm} \]
\[ A_{eff} = 5.8 \text{ cm}^2 \]

Factor, $Q = A_{eff} / A = 1.0 = C_e = \frac{2}{\pi} \sqrt{\frac{E}{F_y}} = 106.6$

Slenderness limit $= \frac{C_e}{Q} = 106.6 < 137.6$

\[ F_{a1} = \frac{10,680,000}{(kL/r)^2} = 564.1 \text{ kgf/cm}^2 \]

Maximum allowable compressive stress for flexural torsional buckling (ref. cl 6.6.1.2 of IS 801)

Polar radius of gyration, $r_0 = \sqrt{r_x^2 + r_y^2 + x_0^2} = 5.181 \text{ cm}$

\[ \beta = 1 - \left(\frac{x_0}{r_0}\right)^2 = 0.259 \]
\[ \sigma_t = 2,036 \text{ kgf/cm}^2 \]
\[ \sigma_{ex} = 2,480 \text{ kgf/cm}^2 \]

\[ \sigma_{TP0} = \frac{1}{2F_y} \left[ (\sigma_{ex} + \sigma_t) \cdot \sqrt{(\sigma_{ex} + \sigma_t)^2 - 4 \beta \times \sigma_{ex} \times \sigma_t} \right] = 1,201 \text{ kgf/cm}^2 = 117.8 \text{ MPa} \]

1,201 kgf/cm$^2$ $< 0.5 \times F = 1,800 \text{ kgf/cm}^2$

\[ F_{a2} = 0.522 \times \sigma_{TP0} = 626.9 \text{ kgf/cm}^2 \]

The allowable compressive stress, $F_a$ is the minimum of $F_{a1}$ and $F_{a2}$.

\[ F_a = 546.1 \text{ kgf/cm}^2 = 55.32 \text{ MPa} \]

**Allowable Bending Strength**

$C = 1.0$ for member under combined axial and bending.

\[ F_b = \frac{2}{5} F_y \cdot \frac{F_y}{54\pi^2 E} \cdot C_b \left( \frac{L^2 S_{xc}}{d \times t_{yc}} \right) = 1,412 \text{ kgf/cm}^2 = 138.5 \text{ MPa} \]  

(ref. cl 6.3)

Maximum allowable compressive stress:
F_b1 = 0.6 \times F_y = 2,160 \text{ kgf/cm}^2 = 211.8 \text{ MPa}

**Allowable Shear Strength**

\[
\frac{h}{t} = 13 < \frac{4.590}{\sqrt{F_y}} = 76.5
\]

\[
F_{v1} = \frac{1.275 \cdot \sqrt{F_y}}{(h/t)} = 5,884 \text{ kgf} \mid \text{cm}^2
\]

\[
F_{v2} = 0.4F_y = 1,440 \text{ kgf} \mid \text{cm}^2
\]

The allowable shear stress, \(F_v\), is the minimum of \(F_{v1}\) and \(F_{v2}\):

\[
F_v = 1,440 \text{ kgf/cm}^2 = 141.3 \text{ MPa}
\]

**Axial and Bending Interaction**

\[
f_a = \frac{P}{A} = 10 \text{ kN} / 5.8 \text{ cm}^2 = 1,019.7 \text{ kgf} / 5.8 \text{ cm}^2 = 175.8 \text{ kgf/cm}^2
\]

\[
f_{b1} = \frac{M}{Z} = 4.0 \text{ kN} \cdot \text{m} / 9.4 \text{ cm}^3 = 40,789 \text{ kgf} \cdot \text{cm} / 9.4 \text{ cm}^3 = 4,339 \text{ kgf/cm}^2
\]

\[
C_{mx} = 0.6
\]

\[
F'_e = 1,294 \text{ kgf/cm}^2
\]

\[
\frac{f_a}{F_{a1}} + \frac{f_{b1} C_{m}}{F_{b1}} = \frac{175.8}{564.1} + \frac{4,390(0.6)}{2,160} = 0.312 + 1.395 = 1.705
\]

Hence, not OK

\[
F_{a0} = 1,879 \text{ kgf/cm}^3
\]

\[
\frac{f_a}{F_{a0}} + \frac{f_{b1}}{F_{b1}} = \frac{175.8}{1,879} + \frac{439}{2,160} = 0.094 + 2.009 = 2.103
\]

### V. Japan

#### V.AIJ 2002

**V.AIJ 2002 Check for MBG parameter**

Verify the effect of the MBG parameter of the AIJ 2002 code on a doubly symmetric I shaped beam of span 6m, that is subjected to UDL of -20 KN/m on its span.

**Details**

Japanese H Shape Doubly Symmetric I Section H400X200X12X22 used in the following frame, E = 205,000 MPa, $F_y = 235$ MPa
where $w = -20 \text{kN/m}$ and $L = 4 \text{ m}$

Equation SSB-1.10 of JSME is used to evaluate Young’s modulus, $E$, for equation 5.8 ($\text{YNG ~1}$).

d = 400 mm, $b_f = 200 \text{ mm}$, $t_w = 12 \text{ mm}$, $t_f = 22 \text{ mm}$

**Verification**

Maximum Moment, $MZ_1 = 43.714 \text{ kN}\cdot\text{m}$

Minimum Moment, $MZ_2 = 43.714 \text{ kN}\cdot\text{m}$

Span Moment = $46.286 \text{ kN}\cdot\text{m}$

Unbraced length of compression flange, $l_b = 6,000 \text{ mm}$

**Note:** Only the flanges will be considered (i.e., the web is ignored for calculating the section modulus). ($\text{MBG ~1}$)

Area of compression flange = $A_f = b_f \times t_f = 4,400 \text{ mm}^2$

$$C_g = \frac{b_f \times t_f \times \left( d - \frac{t_f}{2} \right) + b_f \times t_f \times \frac{t_f}{2}}{(b_f \times t_f) + (b_f \times t_f)} = 200 \text{ mm}$$

$$I_{zz} = 2 \times \left( b_f \times \frac{t_f^3}{12} \right) + 2 \times b_f \times t_f \times \left( c_g \cdot \frac{t_f}{2} \right)^2 = 3.147 \times (10)^8 \text{ mm}^4$$

Elastic Section Modulus about Z axis on compression side $Z_{zc} = I_{zz}/c_g = 1.573 \times 10^6 \text{ mm}^3$

$I_{yc} = t_f \times b_f^3/12 = 1.467 \times 107 \text{ mm}^4$

$A_C = t_f \times b_f = 4,400 \text{ mm}^2$

$r_i = \sqrt{I_{yc}/A_C} = 57.735 \text{ mm}$
Bending Moment Factor $C = 1.75 - 1.05 \times (-MZ2/MZ1) + 0.3 \times (-MZ2/MZ1)^2 = 3.198$, but not more than 2.3

As Span moment $> MZ1$, $C$ will be 1

Allowable slenderness ratio $\Lambda = \sqrt{\frac{n^2 \times E}{0.6 \times F_{YLD}}} = 119.789$

$$f_{b1} = 1.5 \times \left[ 1 \times 0.4 \times \left( \frac{l_b}{C \times A} \right)^2 \right] \times \frac{f_t}{\gamma} = 109.501 \text{ N/mm}^2$$

As per Eq. SSB-1.10 for $YNG = 1$:

$$f_{b2} = 1.5 \times \frac{0.433 \times E}{l_b \times d} = 162.736 \text{ N/mm}^2$$

$$f_{bz1} = \max (f_{b1}, f_{b2}) = 162.736 \text{ N/mm}^2$$

Allowable tensile bending stress, $f_{bzt} = f_{t} = 156.667 \text{ N/mm}^2$

Actual tensile bending stress about Z axis = $46.286/Z_{ZC} = 29.425 \text{ N/mm}^2$

Utilization ratio = Actual bending stress/Allowable bending stress = $29.425/156.667 = 0.1878$

Allowable compressive bending stress, $f_{bzc} = \min (f_{bz1}, f_{t}) = 156.667 \text{ N/mm}^2$

Actual compressive bending stress about Z axis = $46.286/Z_{ZC} = 29.425 \text{ N/mm}^2$

Utilization ratio = Actual bending stress/Allowable bending stress = $29.425/156.667 = 0.1878$

**V.AIJ 2002 Check for MISES parameter**

Verify the von Mises stress calculations per the AIJ 2002 code using a cantilever beam.
Details

Japanese Angle section L250X250X35, $E = 205,000$ MPa, $F_y = 200$ MPa

The member is a 5 m cantilever with the following applied loads at the end:

- $F_x = 10$ kN
- $V_z = 5$ kN
- $V_y = 5$ kN
- $T = 5$ kN-m

Verification

The maximum of the left-hand side of the von Mises stress equation apparently occurs at the fixed support of the beam. Section forces at the fixed end are calculated as below.

- $F_X = -10$ KN
- $F_Y = -5$ KN
- $F_Z = -5$ KN
- $M_X = -5$ KN-m
- $M_Y = 25$ KN-m
- $M_Z = -25$ KN-m

The standard AIJ calculation is used ($MISES ~1$). From these section forces, $\sigma_x$ and $\tau_{xy}$ at the section of the fixed end are calculated:

$$\sigma_x = \sqrt{\frac{F_x}{A_x} + \frac{M_y}{Z_y} + \frac{M_z}{Z_z}}$$

$$= \sqrt{\frac{-10,000}{16,260} + \frac{25,000,000}{838,660} + \frac{-25,000,000}{355,900}}$$

$$= 0.615 + 29.809 + 70.244 = 100.668 \text{ N/mm}^2$$

$$\tau_{xy} = \sqrt{\frac{M_x}{A_x} + \frac{F_y}{A_y}^2 + \frac{F_z}{A_z}^2}$$

$$= \sqrt{\frac{5,000,000}{189,700} + \frac{5,000}{5,833}^2 + \frac{5,000}{5,833}^2}$$

$$= 27.57 \text{ N/mm}^2$$

From $\sigma_x$ and $\tau_{xy}$, $f_m$ is calculated:

$$f_m = \sqrt{\sigma_x^2 + 3\tau_{xy}^2} = 111.42 \text{ N/mm}^2$$

For permanent loading, $k = 1$ and $f_t = f_y / 1.5 = 133.33 \text{ N/mm}^2$

Therefore, the ratio $= f_m / k \times f_t = 111.419 / (1 \times 133.33) = 0.836$
Results

V. New Zealand

V. NZS 3404 1997

V. NZS3404 1997-UB Section
Verify the Design Capacity of I Section as per NZS3404 1997.

Details
Verify the section bending capacity of an UB530X92.4. The member is used in a 15 m simply supported span.

Validation

Section Classification
Evaluate the slenderness the beam flanges:

\[ \lambda_{ef} = \left( \frac{B}{2t_f} \right) \times \sqrt{\left( \frac{f_y}{250} \right)} = \frac{198.8}{(2 \times 15.60)} \times \sqrt{300/250} = 6.98 < 8 \]

Flange is compact.

Evaluate the slenderness of the beam web:

\[ \lambda_{ew} = \left( \frac{d}{t_w} \right) \times \sqrt{\left( \frac{f_y}{250} \right)} = \frac{501.80}{10.20} \times \sqrt{300/250} = 53.89 < 89 \]

Web is compact.

Bending Capacity

Section Bending Capacity About Strong Axis
Effective section modulus, \( Z_{ez} = 2.37(10)^6 \text{ mm}^3 \)

The nominal section capacity in bending about the Z axis, \( M_{sz} = \phi f_y \times Z_{ez} \)

\[ M_{sz} = 0.9 \times 300 \times 2.37 = 639.9 \text{ kN m} \]

Section Bending Capacity About Weak Axis
Effective section modulus, \( Z_{ey} = 341.6(10)^3 \text{ mm}^3 \)

The nominal section capacity in bending about the Y axis, \( M_{sy} = \phi f_y \times Z_{ey} \)

\[ M_{sy} = 0.9 \times 300 \times 341.6 \times (10)^3 = 92.24 \text{ kN m} \]

Member Bending Capacity
End restraint arrangement = FF
A twist restraint factor, \( K_t(SKT) = 1.00 \)
Minor axis rotation restraints = Both
Lateral rotation restraint factor, \( K_r(SKR) = 1 \)
Load Height factor, \( K_l(LHT) = 1.00 \) (Table 5.6.3(2) of NZS3404:1997)
Effective length = 1×1×1×15,000 = 15,000 mm

Design Bending Moment, \( M_m = 160.8 \text{ kN} \cdot \text{m} \)

Quarter Point Moment of segment, \( M_2 = -72.443 \text{ kN} \cdot \text{m} \)

Mid-Point Moment of segment, \( M_3 = -2.267 \text{ kN} \cdot \text{m} \)

Quarter Point Moment of segment, \( M_4 = 72.499 \text{ kN} \cdot \text{m} \)

\[ \alpha_m = \frac{1.7M_m}{\sqrt{M_1^2 + M_2^2 + M_3^2}} \leq 2.5 \]

\[ \alpha_m = \frac{1.7 \times 160.8}{\sqrt{(-72.443)^2 + (-2.267)^2 + (72.499)^2}} = 2.66 \]

Therefore, \( \alpha_m = 2.5 \)

Reference Buckling Moment, \( M_o \)

\[ M_o = \sqrt{\frac{n^2EI_y}{L_e^2}} \left[ GJ + \left( \frac{n^2EI_y}{L_e^2} \right) \right] = 127.0 \text{ kN} \cdot \text{m} \]

\[ \alpha_s = 0.6 \left[ \left( \frac{M_{sx}}{M_{oa}} \right)^2 + 3 \right] \left( \frac{M_{sx}}{M_{oa}} \right) = 0.157 \]

\[ M_{bz} = \alpha_m \alpha_s M_{sx} \leq M_{sx} = 2.5 \times 0.157 \times 71 = 279.1 \text{ kN} \cdot \text{m} \]

\[ \phi_{M_{bz}} = 251.2 \text{ kN} \cdot \text{m} \]

**Check for Shear**

Shear Area of the section, \( A_y = d \times t_w = 533.0 \times 10.2 = 5,436.6 \text{ mm}^2 \)

Section Shear Capacity (Along Y axis), \( V_y = 0.6 \times f_y \times A_y = 0.6 \times 320 \times 5,436.6 = 1,044 \text{ kN} \)

\( ZV_y = 0.9 \times 1,044 = 939.4 \text{ kN} \)

Shear Area of the section, \( A_Z = 2 \times b_f \times t_f = 2 \times 209 \times 15.6 = 6,520.8 \text{ mm}^2 \)

Section Shear Capacity (Along Z axis), \( V_z = 0.6 \times f_y \times A_Z = 0.6 \times 300 \times 6,520.8 = 1,174 \text{ kN} \)

\[ \phi_{V_z} = 1,056 \text{ kN} \]

**Check for Axial Compression**

Section Compression Capacity

The flange slenderness, \( \lambda_{eb} = 6.98 \) [Ref : Cl no - 6.2.3.1]

Yield slenderness for flange, \( \lambda_{eby} = 16.00 \) [Ref : Table 6.2.4]

The web slenderness, \( \lambda_{ew} = 55.66 \)

Yield slenderness for web, \( \lambda_{eby} = 45 \)

Effective Width, \( b_e = 209 \text{ mm} \)

Effective Depth, \( DE = 405.7 \text{ mm} \)

Gross Area, \( A_g = 11,800 \text{ mm}^2 \)
Net Area, \( A_n = 10,820 \, \text{mm}^2 \)

Form factor, \( K_f = \frac{A_e}{A_g} = 0.917 \)

The nominal member section capacity for axial compression, 
\[ N_s = K_f \times A_n \times f_y = 0.917 \times 10,819.8 \times 300 = 3,246 \, \text{kN} \]
\[ \phi N_s = 0.9 \times 3,246 = 2,920 \, \text{kN} \]  
[Ref : Cl no - 6.2.1]

**Member Compression Capacity**

Effective length factor for slenderness & buckling about minor Y-axis, \( K_y = 1.00 \)

Effective length factor for slenderness & buckling about minor Z-axis, \( K_z = 1.00 \)

Effective Length of member, \( L_{ez} = 15,000 \, \text{mm} \)

Effective Length of member, \( L_{ey} = 15,000 \, \text{mm} \)

Geometrical Slenderness Ratio = 69.23

Geometrical Slenderness Ratio = 334.0

Member slenderness, \( \lambda_{nz} = \frac{L_{ez}}{r} \times \sqrt{K_f} \times \sqrt{f_y/250} \)  
\[ \lambda_{nz} = 69.23 \times \sqrt{1} \times \sqrt{300/250} = 72.62 \]  
[Ref : Cl no - 6.3.3.]

Member slenderness, \( \lambda_{ny} = \frac{L_{ey}}{r} \times \sqrt{K_f} \times \sqrt{f_y/250} \)  
\[ \lambda_{ny} = 334 \times \sqrt{1} \times \sqrt{300/250} = 350.35 \]  
[Ref : Cl no - 6.3.3]

\[ a_{az} = (\lambda_{nz} - 13.5)/(\lambda_{nz}^2 - 15.3\lambda_{nz} + 2,050) = 19.984 \]

\[ a_{ay} = (\lambda_{ny} - 13.5)/(\lambda_{ny}^2 - 15.3\lambda_{ny} + 2,050) = 5.923 \]

\[ a_b = 0.00 \]  
[Ref : table 6.3.3(2)]

\[ \lambda_z = \lambda_{nz} + a_{az}a_b = 72.62 \]

\[ \lambda_y = \lambda_{ny} + a_{ay}a_b = 350.35 \]

\[ \eta = 0.19 \]

\[ \eta = 1.10 \]

\[ \xi_z = ((\lambda_z/90)2 + 1 + \eta)/(2 \times (\lambda_z/90)2) = 1.42 \]

\[ \xi_y = ((\lambda_y/90)2 + 1 + \eta)/(2 \times (\lambda_y/90)2) = 0.57 \]

\[ a_{cz} = 0.731 \]  
[Ref : Cl no - 6.3.3]

\[ a_{cy} = 0.061 \]  
[Ref : Cl no - 6.3.3]

The nominal member capacity, \( N_{cz} = a_{cz} \times N_s \)  
\[ N_{cz} = a_{cz} \times N_s = 0.731 \times 3,246 = 2,373 \, \text{kN} \]

\[ \phi N_{cz} = 2,136 \, \text{kN} \]

The nominal member capacity, \( N_{cy} = a_{cy} \times N_s \)  
\[ N_{cy} = a_{cy} \times N_s = 0.061 \times 3,246 = 198.9 \, \text{kN} \]

\[ \phi N_{cy} = 178.96 \, \text{kN} \]

**Nominal Section Tension Capacity**

Ref. Cl 7.1
\[ K_t = 1.00 \]
\[ N_{t1} = A_g \times f_y = 3,540 \text{kN} \]
\[ N_{t2} = 0.85 \times K_t \times A_n \times f_u = 4,413 \text{kN} \]
\[ \phi_{Nt} = 3,186 \text{kN} \] [Ref: Cl no - 5.6.1.1.1(a)]

MEMBER DESIGN OUTPUT FOR PMEMBER 5

DESIGN Notes

1. (*) next to a Load Case number signifies that a P-Delta analysis has not been performed for that particular Load Case; i.e. analysis does not include second-order effects.

2. \( f = 0.9 \) for all the calculations [NZS3404 Table 3.4]

3. (#) next to Young's modulus \( E \) indicates that its value is not 200000 MPa as per NZS3404 1.4.

**DESIGN SUMMARY**

---------------

Designation: ST UB530X92.4 (AISC SECTIONS)

Governing Load Case: 1*

Governing Criteria: Cl. 12.8.3.1.1

Governing Ratio: 14.910 *(FAIL)

Governing Location: 10.015 m from Start.

**SECTION PROPERTIES**

V. United Kingdom

V. Steel Design per BS 5950-1:2000

V. BS5950 2000 - Fully Restrained Simply Supported Beam

A 6.5 m, simply-supported beam is fully restrained along its length. The beam is designed in S275 steel for the loading described.

Reference

Problem

The beam is designed in S275 steel for the loading described.

Dead Loads, $\gamma_{fd} = 1.4$:
- Distributed load (including s/w) $w_d = 15 \text{ kN/m}$
- Point Load $W_d = 40 \text{ kN}$

Imposed Loads, $\gamma_{fi} = 1.6$:
- Distributed load $W_i = 30 \text{ kN/m}$
- Point Load $W_i = 50 \text{ kN}$

Comparison

V. BS5950 2000 - Unrestrained Simply Supported Beam

Design of a 9 m, unrestrained beam with end moments.

Reference

Problem

Intermediate point loads are applied to the bottom flange. These do not provide restraint against lateral-torsional buckling. The beam is designed in S275 steel.

Dead Loads, $\gamma_{fd}$ = 1.4:

- Selfweight $w_s = 3 \text{ kN/m}$
- Point Load $W_{1d} = 40 \text{ kN}$
- Point Load $W_{2d} = 20 \text{ kN}$

Imposed Loads, $\gamma_{fi}$ = 1.6:

- Point Load $W_{1i} = 60 \text{ kN}$
- Point Load $W_{2i} = 30 \text{ kN}$

### V. BS5950 2000 - Beam from UB Restrained at Loading

Design of a simply-supported, 9m beam, which is laterally restrained at the ends and at the points of load application only.

**Reference**

**Problem**

Dead Loads, \( \gamma_{fd} = 1.4 \):

- Selfweight \( w_s = 3 \text{ kN/m} \)
- Point Load \( W_{1d} = 40 \text{ kN} \)
- Point Load \( W_{2d} = 20 \text{ kN} \)

Imposed Loads, \( \gamma_{fi} = 1.6 \):

- Point Load \( W_{1i} = 60 \text{ kN} \)
- Point Load \( W_{2i} = 30 \text{ kN} \)
Comparison

Table 530: Comparison of results

STAAD.Pro 3807 User Manual
V. BS5950 2000 - Beam from UC Restrained at Loading

Design of a simply-supported, 9m beam, which is laterally restrained at the ends and at the points of load application only.

Reference

Problem

The beam is a universal column from S355 steel.

Loads:

- Selfweight \( w_s' = 3.4 \text{kN/m} \)
- Point Load \( W_1' = 122 \text{kN} \)
- Point Load \( W_2' = 61 \text{kN} \)

V. AASHTO

V. AASHTO 17th Ed ASD - Design Frame
The following compares the solution of a design performed using STAAD.Pro against a hand calculation.

Reference

Related Links
- D1.D.1 AASHTO (ASD) (on page 1464)

Problem
Determine the allowable stresses (AASHTO code) for the members of the structure as shown in figure. Also, perform a code check for these members based on the results of the analysis.

Members 1, 2 = W12X26, Members 3, 4 = W14X43
Members 5, 6, 7 = W16X36, Member 8 = L40404,
Member 9 = L50506

The frame is subject to the following load cases:

1. a uniform gravity load along the beam, \( w = 2 \text{ kips/ft} \) (dead + live)
2. a lateral wind load, \( F = 15 \text{ kips} \)
3. a combination of 75\% of load 1 and 75\% of load 2

**Solution**

Only the AASHTO steel design elements are check here. No structural analysis calculations are included in these hand verifications.

Though the program does check shear per the AASHTO specifications, those calculations are not reflected here. Only the controlling stress ratios are presented.

As all members are grade 36 steel, the following critical slenderness parameter applies to each:

\[
C_c = \sqrt{\frac{2\pi^2 E}{F_y}} = \sqrt{\frac{2\pi^2 \times 29,000}{36}} = 126.1
\]

**Member 1**

Size W 12X26, \( L = 10 \text{ ft} \), \( a = 7.65 \text{ in} \), \( S_z = 33.39 \text{ in}^3 \)

From observation, Load case 1 will govern

- \( F_x = 25.0 \text{ kip (compression)} \)
- \( M_z = 56.5 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\[
FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi}
\]

**Bending Major Axis**

\[
F_{cz} = \frac{50(10)^6C_b}{S_{xc}} \left( I_{yc} \right) \left( 0.772 \frac{J}{I_{yc}} + 9.87 \left( \frac{d}{1} \right)^2 \right) \leq 0.55F_y
\]

Where:

\[
C_b = 1.75 + 1.05(M1/M2)+0.3x(M1/M2)^2
\]

\( M1 = 0 \), so \( C_b = 1.75 \)

\( S_{xc} = \) Section modulus with respect to the compression flange \( = \frac{204}{0.5 \cdot 12.22} = 33.38789 \text{ in}^3 \)

\[
I_{YC} = t_b^3/12 = 0.38 \cdot 6.49^3/12 = 8.6564 \text{ in}^4
\]

\[
J = (2 \times 6.49 \cdot 0.38^3+ (12.22 – 2 \cdot 0.38) \cdot 0.23^3)/3 = 0.28389 \text{ in}^4
\]

\[
F_{cz} = \frac{50(10)^61.75}{33.38789} \left( \frac{8.6564}{120} \right) \left( 0.772 \frac{0.28389}{8.6564} + 9.87 \left( \frac{11.46}{120} \right)^2 \right) \leq 0.55 \cdot 19.8 = 64.375 \text{ ksi}
\]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{cz} = 19.8 \text{ ksi} \)

**Axial Compression**

Critical \( (kL/r) = 1.0 \cdot 120/1.5038 = 79.7978 \)

As \( (kL/r) < C_c \), the allow axial stress in compression is given by:
Actual Stress

Actual axial stress, \( f_a = \frac{25}{7.65} = 3.26 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10.36 to calculate the design ratio.

Actual bending stress = \( f_{bz} = 56.5 \cdot 12 / 33.4 = 1.692 \cdot 12 = 20.3 \text{ ksi} \)

\[
F_{ez} = \frac{n^2E}{F.S.(kL/r)^2} = \frac{n^229,000}{2.12(120/5.17)^2} = 250.6 \text{ksi}
\]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42

\[
\frac{f_a}{F_a} + \frac{C_{mz}f_{bz}}{F_{bz}} + \frac{C_{my}f_{by}}{F_{by}} = \frac{3.26}{13.58} + \frac{0.58 \cdot 20.3}{19.8} + 0 = 1.122
\]

For the end section, use Equation 10.43:

\[
\frac{f_a}{0.472F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{3.26}{0.472(36)} + \frac{20.3}{19.8} + 0 = 1.217
\]

The critical stress ratio is thus 1.217. The value calculated by STAAD is 1.218

**Member 2**

Size W 12X26, L = 5 ft., \( a = 7.65 \text{ in}^2, Sz = 33.4 \text{ in}^3 \)

From observation Load case 1 will govern, Forces at the midspan are

- \( F_x = 8.71 \text{ kip (compression)} \)
- \( M_z = 56.5 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\( F_{TY} = F_{TZ} = 0.55 \cdot F_Y = 19.8 \text{ ksi} \)

**Bending Major Axis**

\[
F_{cz} = \frac{50(10)^6C_b}{S_{xc}} \left( \frac{I_{xc}}{I_{yc}} \right) \left( \frac{0.772 \frac{f}{f_{yc}} + 9.87 \frac{d}{I_{yc}})^2}{0.55F_y} \right) \leq 0.55F_y
\]

Where:

\( C_b = 1.75 + 1.05(M1/M2)+0.3x(M1/M2)^2 \)

\( M1 = 39.44 \text{ and } M2 = 677.96, \text{ so } C_b = 1.69 \)

\( S_{xc} = \text{Section modulus with respect to the compression flange} = 204/(0.5 \cdot 12.22) = 33.38789 \text{ in}^3 \)
\[ I_{YC} = t^3/12 = 0.38 \cdot 6.49^3/12 = 8.6564 \text{ in}^4 \]
\[ J = (2 \cdot 6.49 \cdot 0.38)^3 + (12.22 - 2 \cdot 0.38) \cdot 0.23^3/3 = 0.28389 \text{ in}^4 \]
\[ F_{ez} = \frac{50(10)^{6/3}}{33.33739} \left( \frac{8.6564}{60} \right) \left( 0.772 \cdot \frac{0.28389}{8.6564} + 9.87 \left( \frac{11.46}{60} \right)^2 \right)^{10^{-3}} = 227.34 \text{ ksi} \]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{CZ} = 19.8 \text{ ksi} \)

**Axial Compression**

Critical \( (kL/r) = 1.0 \cdot 60/1.504 = 39.92 \)

As \( (kL/r) < C_c \), the allow axial stress in compression is given by:

\[ F_a = \frac{F_y}{F.S.} \left[ 1 - \frac{(kL/r)^2 F_y}{4\pi^2 E} \right] \]
\[ = \frac{36}{2.12} \left[ 1 - \frac{(39.92)^2 36}{4\pi^2 29,000} \right] = 16.13 \text{ ksi} \]

**Actual Stress**

Actual axial stress, \( f_a = 8.71 / 7.65 = 1.138 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress = \( f_{bz} = 56.5 \cdot 12/33.4 = 1.691 \cdot 12 = 20.3 \text{ ksi} \)

\( (KL/r)_z = 1 \cdot 60/5.16 = 11.618 \)

\[ F_{ez} = \frac{x^2 E}{F.S.(kL/r)^2} \]
\[ = \frac{229,000}{2.12(11.618)^2} = 998.5 \text{ ksi} \]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42

\[ \frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{F_{bz}} + \frac{C_{my} f_{by}}{F_{by}} = \frac{1.138}{16.13} + \frac{0.58 \cdot 20.3}{19.8} + 0 = 0.942 \]

For the end section, use Equation 10.43:

\[ \frac{f_a}{0.472 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{1.138}{0.472(36)} + \frac{20.3}{19.8} + 0 = 1.092 \]

The critical stress ratio is thus 1.092. The value calculated by STAAD is 1.093.

**Member 3**

Size W 14X43, L = 11 ft., \( a = 12.6 \text{ in}^2 \), \( Sz = 62.7 \text{ in}^3 \)

From observation Load case 3 will govern, Forces at the end are

- \( F_x = 25.5 \text{ kip (compression)} \)
- \( M_x = 112.17 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:
FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi}

**Bending Major Axis**

\[ F_{cz} = \frac{50(10)^6 C_b}{S_{xc}} \left( \frac{I_{yc}}{I_{yc}^2} \right) \left[ 0.772 \frac{J}{I_{yc}} + 9.87 \left( \frac{d}{r} \right)^2 \right] \leq 0.55 F_Y \]

Where:

\[ C_b = 1.75 + 1.05(M_1/M_2) + 0.3x(M_1/M_2)^2 \]

\[ M_1 = 0, \text{ so } C_b = 1.75 \]

\[ S_{zc} = \text{Section modulus with respect to the compression flange} = \frac{428}{0.5 \cdot 13.66} = 62.7 \text{ in}^3 \]

\[ I_{YC} = \frac{tb}{12} = 0.53 \cdot 8.0 \frac{3}{12} = 22.61 \text{ in}^4 \]

\[ J = \frac{2 \cdot 8.0 \cdot 0.53 + (13.66 - 2 \cdot 0.53) \cdot 0.305}{3} = 0.917 \text{ in}^4 \]

\[ F_{cz} = \frac{50(10)^6 1.75}{62.7} \left( \frac{22.61}{12.6} \right) \left[ 0.772 \frac{0.917}{22.61} + 9.87 \left( \frac{12.6}{132} \right)^2 \right] 10^{-3} = 83.19 \text{ ksi} \]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{cz} = 19.8 \text{ ksi} \)

**Axial Compression**

Critical \( (kL/r) = 1.0 \cdot 132/1.894 = 69.69 \)

As \( (kL/r) < C_c \), the allow axial stress in compression is given by:

\[ F_a = \frac{F_y}{F.S.} \left( 1 - \frac{(kL/r)^2 F_y}{\pi^2 E} \right) = \frac{36}{2.12} \left( 1 - \frac{(69.69)^2 36}{\pi^2 29,000} \right) = 14.39 \text{ ksi} \]

**Actual Stress**

Actual axial stress, \( f_a = 25.5 / 12.6 = 2.024 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress \( f_{bz} = 112.17 \cdot 12/62.7 = 1.789 \cdot 12 = 21.467 \text{ ksi} \)

\( (KL/r)_e = 1 \cdot 132/5.828 = 22.649 \)

\[ F_{ez} = \frac{n^2 E}{F.S.(kL/r)^2} = \frac{n^2 29,000}{2.12(22.648)^2} = 263.18 \text{ ksi} \]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42

\[ \frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{F_{bz}} + \frac{C_{my} f_{by}}{F_{by}} = \frac{2.024}{14.39} \frac{0.58 \cdot 21.467}{263.21^{19.8}} + 0 = 1.069 \]

For the end section, use Equation 10.43:

\[ \frac{f_a}{0.472 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{2.024}{0.472(36)} + \frac{21.467}{19.8} + 0 = 1.203 \]

The critical stress ratio is thus 1.203. The value calculated by STAAD is 1.204.
Member 4
Size W 14X43, L = 4 ft., a = 12.6 in², Sz = 62.6 in³
From observation Load case 3 will govern, Forces at the end are
- \( F_x = 8.75 \text{ kip (tension)} \)
- \( M_z = 112.17 \text{ k-ft} \)
Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**
Allowable minor axis bending stress:
\[
FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi}
\]

**Bending Major Axis**
\[
F_{cz} = \frac{50(10^6)C_b}{S_{xc}} \left( \frac{I_{xc}}{I} \right) \sqrt{0.772 \frac{J}{I_{yc}} + 9.87 \left( \frac{d}{I} \right)^2} \leq 0.55F_y
\]
Where:
\[
C_b = 1.75 + 1.05(M1/M2)+0.3 \cdot (M1/M2)^2
\]
\[
M1 = -191.36 \text{ Kip-in }, M2 = -1346.08 \text{ Kip-in so } C_b = 1.606
\]
\[
I_{YC} = \frac{tb^3}{12} = 0.53 \cdot \frac{8.0^3}{12} = 22.61 \text{ in}^4
\]
\[
J = (2 \cdot 8.0 \cdot 0.53^3 + (13.66 - 2 \cdot 0.53) \cdot 0.305^3)/3 = 0.913 \text{ in}^4
\]
\[
F_{cz} = \frac{50(10^6)1.606}{62.6} \left( \frac{22.61}{48} \right) \sqrt{0.772 \frac{0.911}{22.61} + 9.87 \left( \frac{12.6}{48} \right)^2} \cdot 10^{-3} = 508.8 \text{ ksi}
\]
which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{cz} = 19.8 \text{ ksi} \)

**Axial Tension**

**Note:** No connection information is specified and no reduction of section is assumed.

\[
F_t = 0.55 \cdot F_Y = 19.8 \text{ ksi}
\]

**Actual Stress**
Actual axial stress, \( f_a = 8.75 / 12.6 = 0.694 \text{ ksi} \)
Actual bending stress = \( f_{bz} = 112.17 \cdot 12 / 62.7 = 1.789 \cdot 12 = 21.47 \text{ ksi} \), which exceeds \( F_{cz} \).
\[
f_{bz}/F_{cz} = 21.47/19.8 = 1.084
\]
The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.43 in section 10-36 to calculate the design ratio for the end section.
\[
\frac{f_a}{0.472F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{0.694}{0.472(36)} + \frac{21.47}{19.8} + 0 = 1.125
\]
The critical stress ratio is thus 1.125. The value calculated by STAAD is 1.126.

Member 5
Size W 16X36, L = 5 ft., a = 10.6 in², Sz = 56.5 in³
From observation Load case 3 will govern, Forces at the end are

- \( F_x = 14.02 \) kip (compression)
- \( M_z = 57.04 \) k-ft

Calculate the allowable stress as per Table 10.32.1A.

### Bending Minor Axis

Allowable minor axis bending stress:

\[ F_{ty} = F_{tz} = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

### Bending Major Axis

\[
F_{ez} = \frac{50(10)^6 C_b}{S_{xc}} \left( \frac{I_{yc}}{I} \right) \left[ 0.772 \frac{J}{I_{yc}} + 9.87 \left( \frac{d}{r} \right)^2 \right] \leq 0.55 F_Y
\]

Where:

\[ C_b = 1.75 + 1.05(M1/M2)+0.3 \cdot (M1/M2)^2 \]

\[ M1 = 40.14, M2 = -684.4 \text{ so } C_b = 1.81 \]

\[ S_{xc} = \text{Section modulus with respect to the compression flange} = \frac{448}{0.5 \cdot 15.86} = 56.5 \text{ in}^3 \]

\[ I_{yc} = \frac{tb^3}{12} = 0.43 \cdot 6.99^3/12 = 12.238 \text{ in}^4 \]

\[ J = (2 \cdot 6.99 \cdot 0.43^3 \cdot (15.86 - 2 \cdot 0.43) \cdot 0.29^3)/3 = 0.5 \text{ in}^4 \]

\[
F_{ez} = \frac{50(10)^6 1.81}{56.5} \left( \frac{12.238}{60} \right) \left[ 0.772 \frac{0.5}{12.238} + 9.87 \left( \frac{15}{60} \right)^2 \right] 10^{-3} = 263.1 \text{ ksi}
\]

which is larger than \( 0.55 \cdot F_Y = 19.8 \) ksi, so \( F_{cz} = 19.8 \) ksi

### Axial Compression

Critical \((kL/r) = 1.0 \cdot 60/1.52 = 69.69\)

As \((kL/r) < C_c\), the allow axial stress in compression is given by:

\[
F_a = \frac{F_Y}{F.S.} \left[ 1 - \frac{(kL/r)^2 F_Y}{4\pi^2 E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(39.474)^2 36}{4\pi^2 29,000} \right] = 16.15 \text{ ksi}
\]

### Actual Stress

Actual axial stress, \( f_a = 14.02 / 10.6 = 1.323 \) ksi

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress = \( f_{bz} = 57.04 \cdot 12/56.5 = 1.001 \cdot 12 = 12.115 \) ksi

\((KL/r)_x = 1 \cdot 60/6.5= 9.231\)

\[
F_{ez} = \frac{F_y}{F.S. (kL/r)^2} = \frac{\pi^2 E}{2.12(9.231)^2} = 1, 584.4 \text{ ksi}
\]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42
For the end section, use Equation 10.43:

\[
\frac{f_a}{F_a} + \frac{C_{mz}f_{bz}}{1 - \frac{f_a}{F'_{ez}}}F_{bz} + \frac{C_{my}f_{by}}{1 - \frac{f_a}{F'_{ey}}}F_{by} = \frac{1.323}{16.149} + \frac{0.85 \cdot 12.115}{1 - \frac{1.323}{1.584}} + 0 = 0.602
\]

The critical stress ratio is thus 0.689. The value calculated by STAAD is 0.690.

**Member 6**

Size W 16X36, L = 16 ft, a = 10.6 in², Sz = 56.5 in³

From observation Load case 3 will govern, Forces at the end are

- Fx = 10.2 kip (compression)
- Mz = 62.96 k-ft

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\[ F_{TY} = F_{TZ} = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

**Bending Major Axis**

\[
F_{cz} = \frac{50(10)^6C_b}{S_{xc}} \left(\frac{I}{I_{yc}}\right) \sqrt{0.772 \frac{J}{I_{yc}}} + 9.87 \frac{d^4}{I} \leq 0.55F_Y
\]

Where:

\[
C_b = 1.75 + 1.05(M1/M2) + 0.3 \cdot (M1/M2)^2
\]

M1 = 8.947 M2 = 183.05 so C_b = 1.69

\[
S_{xc} = \text{Section modulus with respect to the compression flange} = \frac{448}{(0.5 \cdot 15.86)} = 56.5 \text{ in}^3
\]

\[
I_{YC} = \frac{tb^3}{12} = 0.43 \cdot 6.99^3/12 = 12.238 \text{ in}^4
\]

\[
J = (2 \cdot 6.99 \cdot 0.43^3 + (15.86 - 2 \cdot 0.43) \cdot 0.29^3)/3 = 0.5 \text{ in}^4
\]

\[
F_{cz} = \frac{50(10)^61.81}{56.5} \left(\frac{12.238}{192}\right) \sqrt{0.772 \cdot 0.5 \frac{12.238}{12.238} + 9.87 \left(\frac{15}{192}\right)^2} \leq 287.9 \text{ ksi}
\]

which is larger than 0.55 \cdot F_Y = 19.8 ksi, so F_{CZ} = 19.8 ksi

**Axial Compression**

Critical \((kL/r) = 1.0 \cdot 192/1.52 = 126.3\)

As \((kL/r) > C_c\), the allow axial stress in compression is given by:

\[
F_a = \frac{n^2E}{F.S. (kL/r)^2} = \frac{n^229, 000}{2.12(126.3)^2} = 8.46 \text{ ksi}
\]

**Actual Stress**
Actual axial stress, \( f_a = \frac{10.2}{10.6} = 0.962 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress = \( f_{bz} = \frac{62.96 \cdot 12}{56.5 \cdot 12} = 1.114 \cdot 12 = 13.37 \text{ ksi} \)

\[
\left(\frac{KL}{r}\right)_a = 1 \cdot \frac{192/6.51}{12} = 29.49
\]

\[
F_{ez} = \frac{n^2E}{F.S.(kL/r)^2} = \frac{n^229.000}{2.12(29.49)^2} = 155.2 \text{ ksi}
\]

From Table 10-36A, \( C_{mx} = 0.85 \)

Equation 10-42

\[
\frac{f_a}{F_a} + \frac{C_{mx}f_{bz}}{F_{ez}} + \frac{C_{my}f_{by}}{F_{by}} = \frac{0.962}{8.46} + \frac{0.85 \cdot 13.37}{19.8} + 0 = 0.691
\]

For the end section, use Equation 10.43:

\[
\frac{f_a}{0.472F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{0.962}{0.472(36)} + \frac{13.37}{19.8} + 0 = 0.732
\]

The critical stress ratio is thus 0.732. The value calculated by STAAD is 0.732

**Note:** The program gives this value when the slenderness check is suppressed (MAIN 1.0 for member 6); otherwise the member fails as a compression member with a slenderness parameter greater than 120).

**Member 7**

Size W 16X36, \( L = 4 \text{ ft}., a = 10.6 \text{ in}^2, Sz = 56.5 \text{ in}^3 \)

From observation Load case 3 will govern, Forces at the midspan are

- \( Fx = 24.05 \text{ kip (tension)} \)
- \( Mz= 62.96 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A

**Bending Minor Axis**

Allowable minor axis bending stress:

\[ FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

**Bending Major Axis**

\[ FCZ = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

**Axial Tension**

**Note:** No connection information is specified and no reduction of section is assumed.

\[ F_a = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

**Actual Stress**

Actual axial stress, \( f_a = \frac{24.05}{10.6} = 2.268 \text{ ksi} \), hence, ok.
Actual bending stress = \( f_{bz} = 62.96 \cdot \frac{12}{56.5} = 1.114 \cdot 12 = 13.37 \text{ ksi} \)

So the combined ratio is

\[
\frac{f_a}{F_a} + \frac{f_{bz}}{F_{TZ}} + \frac{f_{by}}{F_{TY}} = \frac{2.268}{19.8} + 13.37/19.8 + 0 = 0.790
\]

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.43 in section 10-36 to calculate the design ratio for the end section.

\[
\frac{f_a}{0.472F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{2.268}{0.472(36)} + \frac{13.37}{19.8} + 0 = 0.809
\]

The critical stress ratio is thus 0.809. The value calculated by STAAD is 0.809.

**Member 8**

Size L4x4x1/4, \( L = 7.07 \text{ ft} \), \( a = 1.938 \text{ in}^2 \)

From observation Load case 1 will govern, Forces

\( F_x = 23.04 \text{ kip (compression)} \)

Calculate the allowable stress as per Table 10.32.1A

**Axial Compression**

Critical \((KL/r)_y = 1.0 \cdot 7.07 \cdot 12/0.795 = 106.7 \)

As \((kL/r) < C_c \), the allow axial stress in compression is given by:

\[
F_a = \frac{F_y}{F.S.} \left[ 1 - \frac{(kL/r)^2 F_y}{4n^2 E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(106.7)^2}{36} \right] = 10.89 \text{ ksi}
\]

**Actual Stress**

Actual axial stress, \( f_a = 23.04 / 1.938 = 11.88 \text{ ksi} \)

\( f_a / F_a = 11.88/10.89 = 1.091 \)

The value calculated by STAAD is 1.091.

**Member 9**

Size L5x5x3/8, \( L = 5.657 \text{ ft} \), \( A = 3.61 \text{ in}^2 \)

From observation Load case 1 will govern, Forces

\( F_x = 48.44 \text{ kip (compression)} \)

Calculate the allowable stress as per Table 10.32.1A

**Axial Compression**

Critical \((KL/r)_y = 1.0 \cdot 5.567 \cdot 12/0.99 = 68.57 \)

As \((kL/r) < C_c \), the allow axial stress in compression is given by:

\[
F_a = \frac{F_y}{F.S.} \left[ 1 - \frac{(kL/r)^2 F_y}{4n^2 E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(68.57)^2}{36} \right] = 14.47 \text{ ksi}
\]

**Actual Stress**

Verification Examples

STAAD.Pro 3837 User Manual
Actual axial stress, \( f_a = \frac{48.44}{3.61} = 13.42 \text{ ksi} \)

\[ f_a/F_a = \frac{13.42}{14.47} = 0.927 \]

The value calculated by STAAD is 0.928.

V. AASHTO 2nd Ed LRFD - Design Beam

The following compares the solution of a design performed using STAAD.Pro against a hand calculation of steel design per the AASHTO (LRFD) code.

Reference

The following step by step hand calculation as per AASHTO LRFD(1998) code.

Related Links

- [D1.D.2 AASHTO (LRFD)](on page 1468)

Problem

Determine the allowable resistances (AASHTO LRFD, 1998 code) for the member of the structure as shown in figure. Also, perform a code check for the member based on the results of the analysis.

A 48 foot long, non-composite girder is assumed to be simply supported. The section is a plate girder with 16" x 1" plate flanges and a 34" x 3.6" plate web (36 in. total depth). All plates are grade 36 steel.

The beam is subject to a 9.111 kip/ft uniform load.
Solution

\[ A = 154.4 \text{ in}^2, \; I_z = 21,594 \text{ in}^4, \; I_y = 814.9 \text{ in}^4 \]
\[ S_z = \frac{21,594(2)}{36} = 1,200 \text{ in}^3 \]
\[ r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{814.9}{154.4}} = 2.30 \text{ in} \]
\[ r_z = \sqrt{\frac{I_z}{A}} = \sqrt{\frac{21,594}{154.4}} = 11.83 \text{ in} \]

From observation Load case 1 will govern,
\[ M_z = 2,624 \text{ kip-ft} \]

Axial Compression Capacity

Refer Clause 6.9.4 of the code.

\[ (kL/r)_y = 0.333 \times \frac{576}{2.297} = 83.50 \]
\[ (kL/r)_z = \frac{1 \times 576}{11.826} = 48.71 \]
\[ (kL/r)_{\text{crit}} = 83.50 < 120, \text{ ok.} \]

Calculation of Width/Thickness ratio for axial compression

Plate buckling coefficients taken from Table 6.9.4.2-1:
\[ k_w = 1.49, \; k_f = 0.56 \]

Slenderness ratio for the web:
\[ \left( d - 2 \cdot t_f \right)/t_w = \frac{36 - 2 \cdot 1}{3.6} = 9.444 \]

Slenderness ratio for the 1/2 flange:
\[ b_f/(2 \cdot t_f) = \frac{16}{2 \cdot 1} = 8.0 \]

Critical ratio for web:
Critical ratio for flange:

\[ k_f \sqrt{\frac{E}{F_y}} = 0.56 \sqrt{\frac{29,000}{36}} = 15.89 > 8.0 \]

Thus, OK [AASHTO LRFD Cl. 6.4.9.2]

Slenderness ratio about major and minor axis:

\[ \lambda_z = \left( \frac{Kl}{r_z} \right) \frac{F_y}{E} = \left( \frac{1.0 \cdot 576}{11.83} \right)^{\frac{2}{3}} \frac{36}{29,000} = 0.298 \]

\[ \lambda_y = \left( \frac{Kl}{r_y} \right) \frac{F_y}{E} = \left( \frac{0.333 \cdot 576}{2.30} \right)^{\frac{2}{3}} \frac{36}{29,000} = 0.877 \]

\( \lambda_y \) governs, thus \( \lambda = 0.877 \)

\( \lambda < 2.25 \), so Equation 6.9.4.1-1 is used to determine the nominal compressive resistance

\[ P_n = 0.66 \lambda F_y A_s = 0.66 \cdot 0.877 \cdot 36 \cdot 154.4 = 3,861 \text{ kips} \]

The factored compressive resistance,

\[ P_r = \phi c P_n = 0.9 \cdot 3,861 = 3,475 \text{ kips} \]

**Major Axis Bending Capacity**

The compression flange moment of inertia:

\[ I_{yc} = 1(16)^\frac{3}{12} = 341.3 \text{ in}^4 \]

\[ I_{yc}/I_y = 341.3/814.9 = 0.419, > 0.1 \text{ and } < 0.9 \]

Thus, OK [AASHTO LRFD Cl. 6.10.2.1]

\[ \frac{2D_6}{t_w} = \frac{2(17)}{3.6} = 9.445 < 6.77 \sqrt{\frac{E}{F_y}} = 6.77 \sqrt{\frac{29,000}{36}} = 192.1 \]

Thus, OK [AASHTO LRFD Cl. 6.10.2.2]

Calculation of depth of the web in compression at the plastic moment, \( D_{cp} \) (Clause 6.10.3.3.2)

Area of Web, \( A_w = (36 - 2 \times 1) \times 3.6 = 122.4 \text{ in}^2 \)

Area of flange area in tension, \( A_{ft} = 16 \times 1 = 16 \text{ in}^2 \)

\[ D_{cp} = \left( \frac{D_w}{2A_w} \right) F_y \left( A_{ft} + A_w - A_{fc} \right) = \left( \frac{34}{2 \cdot 122.4 \cdot 36} \right) 36 \left( 16 + 122.4 - 16 \right) = 17 \text{ in} \]

\[ \frac{2D_{cp}}{t_w} = \frac{2(17)}{3.6} = 9.445 < 3.76 \sqrt{\frac{E}{F_y}} = 3.76 \sqrt{\frac{29,000}{36}} = 108.1 \]

Thus, OK [AASHTO LRFD Cl. 6.10.4.1.2]

\[ \frac{b_f}{t_f} = \frac{16.0}{21.0} = 0.80 < 0.382 \sqrt{\frac{E}{F_y}} = 0.382 \sqrt{\frac{29,000}{36}} = 10.98 \]

Thus, OK [AASHTO LRFD Cl. 6.10.4.3]

Check clause 6.10.4.1.6a
\[(B/t)_{\text{flange}} < 0.75 \times (B/t)_{\text{flange\_limit}} = 0.75 \times 10.978\]
\[(D/T)_{\text{web}} < 0.75 \times (D/T)_{\text{web\_limit}} = 0.75 \times 108.057\]

Check clause 6.10.4.1.7

\[M_{pz} = P_z \times F_y = 1,600 \text{ in}^3(36 \text{ ksi}) = 57,614 \text{ in-k}\]

\[L_b = \left[0.124 - 0.0759\left(\frac{M_l}{M_{pz}}\right)\right] \times \left[\frac{r_y E}{F_y}\right] = 0.124 - 0.0759\left(\frac{0}{57,614}\right) \times \left[\frac{2.30(29,000)}{36}\right] = 229.5 \text{ in}\]

Unsupported length, \(L_u = 576\) in > \(L_b\); section is non-compact.

Check clause 6.10.4.1.9

A notional section comprised of the compression flange and one-third of the depth of the web in compression, taken about the vertical axis.

\[A_{rt} = A_{cf} + \left(\frac{c - t_f}{3}\right)t_w = 16 + \left(\frac{18 - 1.0}{3}\right)3.6 = 36.4 \text{ in}^2\]

\[I_{rt} = t_f \left[\left(\frac{c - t_f}{3}\right)t_w\right] = 1\left[\left(\frac{18 - 1}{3}\right)\frac{3.6^3}{12}\right] = 363.4 \text{ in}^4\]

\[r_{rt} = \sqrt{\frac{363.4}{36.4}} = 3.149 \text{ in}\]

\[L_p = 1.76\left(3.159\right)\sqrt{\frac{29,000}{36}} = 159.8 \text{ in}\]

\[L_b > L_p\]

Clause 6.10.4.2.6

\[L_r = 4.44\sqrt{\frac{I_{yc}}{S_{xc} \frac{E}{F_y}}} = 4.44\sqrt{\frac{341.3(36)}{1,200 \frac{29,000}{36}}} = 403.3 \text{ in}\]

Minimum radius of gyration of the compression flange taken about the vertical axis:

\[r_l = \sqrt{\frac{I_{yc}}{A_{cf}}} = \sqrt{\frac{341.3}{16}} = 4.619 \text{ in}\]

Hybrid factor, \(R_h = 1.0\) (For Homogeneous sections, Hybrid factors shall be taken as 1.0 per clause 6.10.4.3.1)

As per clause 6.10.4.3.2, Load-shedding factor, \(R_b\)

If area of the compression flange, \(A_{cf} \geq\) the area of the tension flange, \(A_{tf}\)

\[l_f = 5.76\]

\[D_c = 17.00\]

\[\frac{2D_c}{t_w} = \frac{2(17)}{3.6} = 9.445 < L_b\sqrt{\frac{E}{F_y}} = 5.76\sqrt{\frac{29,000}{36}} = 163.5\]

Thus:

\[R_{b,\text{comp}} = R_{b,\text{ten}} = 1.0\]

\[L_r < L_b\]

\[C_b = 1.75 + 1.05(M1/M2) + 0.3x(M1/M2)^2\]

Here \(M1 = 0, M2 = 0\) so \(C_b = 1.75\)
Verification Examples
V.09 Steel Design

\[ M_{nz,\text{comp}} = C_{bz} R_{b,\text{comp}} R_h \frac{M_y \left( \frac{L_r}{L_b} \right)^2}{L_b} = 1.75 \left( \frac{1.0}{1.0} \right) \left( \frac{36(1.200)}{576} \right)^2 = 19,000 \text{kip} \cdot \text{in} \]

\[ M_{nz,\text{ten}} = R_{b,\text{ten}} R_h F_y Z = 1.0(1.0)(36)(1, 200) = 43,188 \text{kip} \cdot \text{in} \]

\[ M_{nz} = 19,000 \text{kip in} \]

Resisting Moment

\[ M_r = Q_f \cdot M_n = 1.0 (19,000) = 19,000 \text{kip in} \]

Actual Moment = 31,488 kip\cdot in

Interaction ratio = 31,488 / 19,000 = 1.657

V. AISC

V. AISC 360-2016

V. Bending

V. AISC 360-16 W Flexural Check LRFD

Verify the flexural yielding strength and lateral torsional buckling of an I section using the LRFD method per AISC 360-16.

References

Details

Verify the flexural yielding strength and lateral torsional buckling of an I section (W12X90) gr. ASTM A992 material, with a member length of 41'-8", and a concentrated moment of 35,000 in-kip applied at midspan. The member is unbraced along its length.

Validation

Flexural yielding about X axis

As the section is compact, nominal flexural yielding strength about X axis is:

\[ M_{nx} = f_y \times Z_{xx} = 65 \text{ ksi} \times 311 \text{ in}^3 = 20,215 \text{ in-kip} \]  \hspace{1cm} (F2-1, ref. 1)
\[ M_x = \phi_c \times M_{nx} = 0.9(20,215 \text{ in·kip}) = 18,193.5 \text{ in·kip} \]

**Flexural yielding about Y axis**

As this is the minor axis, nominal flexural yielding strength about Y axis is:

\[ M_{ny} = f_y \times Z_{yy} = 65 \text{ ksi} \times 143 \text{ in}^3 = 9,295 \text{ in·kip} \]

\[ M_y = \phi_c \times M_{ny} = 0.9(9,295 \text{ in·kip}) = 8,365.5 \text{ in·kip} \]  

**Lateral torsional buckling about X axis**

\[ r_y = \sqrt{I_{yy}/A_g} = 3.243 \text{ in}^2 \]

Limiting laterally unbraced length for the yielding limit state:

\[ L_p = 1.76 \times r_y \frac{E}{F_y} = 120.56\text{in} \]  

\[ r_{ts} = \sqrt{I_{yy} \times C_w}{S_{xx}} = 3.769\text{in} \]

For an I section, \( C = 1 \) (per F2-28a in ref. 1). The limiting unbraced length for the inelastic lateral-torsional buckling limit state is:

\[ h_0 = d - t_f = 12.66 \text{in} \]

\[ L_r = 1.95 \times r_{ts} \frac{E}{0.7F_y} \sqrt{\frac{J_c}{S_{xx}h_0} + \sqrt{\left(\frac{J_c}{S_{xx}h_0}\right)^2 + 6.76\left(\frac{0.7F_y}{E}\right)^2}} = 810.27\text{in} \]

\[ L_p < L_b = 500 \text{ in} < L_r \]

\[ C_b = \frac{12.5M_{max}}{2.5M_{max} + 3M_A + 4M_B + 3M_c} = \frac{12.5(20,000)}{2.5(20,000) + 3(10,000) + 4(20,000) + 3(10,000)} = 1.316 \]

\[ M_p = f_y \times Z_{xx} = 65 \text{ ksi} \times 311 \text{ in}^3 = 20,215 \text{ in·kip} \]

Nominal LTB strength:

\[ M_n = C_b \left[ M_p - \left( M_p - 0.7F_y S_{Sy} \right) \frac{L_b - L_r}{L_p} \right] \leq M_p \]

\[ M_n = 20,611.4 \text{ in·kip} > M_p \]

\( \phi_c M_{nx} = 0.9(20,215 \text{ in·kip}) = 18,193.5 \text{ in·kip} \)

***** DESIGN MESSAGES ***:**

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. Compression

V. AISC 360-16 I Compression LRFD
Verify the flexural buckling capacity of an I section under compressive load using the LRFD method per the AISC 360-16 code.

References

Details
Verify the Flexural Buckling strength of an I Section (W14x90) using the LRFD method

Steel Gr. ASTM A992, about X and Y axis with a member length of 30 ft with dead load 140 kips and Live Load 420 kips.

Validation

Strong axis unbraced length, \( L_x = 360 \text{ in} \)

Torsional axis unbraced length \( L_y = 180 \text{ in} \)

Ultimate load, \( P_u = 1.2(180 \text{ kips}) + 1.6(420 \text{ kips}) = 840 \text{ kips} \)

**Calculation for major axis (X axis)**

From Table C-A-7.1 of ref. 1, \( K = 1.0 \) for a pinned-pinned condition.

\[
\frac{b_f}{2t_f} = 10.211 < 0.56\sqrt{\frac{E}{F_y}} = 13.487 \text{, thus the flange is non-slender.}
\]

Slenderness ratio about X axis \( \frac{K L_x}{r_x} = 58.632 < 4.71\sqrt{\frac{E}{F_y}} = 113.432 \)

Calculate the elastic critical buckling stress: \( F_{eX} = \frac{\pi^2 E}{(K L_x / r_x)^2} = 83.259 \text{ksi} \)

Calculate the flexural buckling stress: \( F_{cX} = 0.658 \frac{F_y}{F_{eX}} F_y = 38.887 \text{ksi} \)

Compressive strength for flexural buckling along X: \( \phi_c P_{nBX} = \phi_c F_{cX} A_g = 947.462 \text{kips} \)

Ratio for flexural buckling strength = 0.906

**Calculation for minor axis (Y axis)**

\[
h = d - 2 \cdot t_f = 12.58 \text{ in}
\]

\[
\frac{h}{w} = 28.591 < 35.884 \text{, thus the flange is non-slender.}
\]

Slenderness ratio about Y axis \( \frac{K L_y}{r_y} = 48.703 < 4.71\sqrt{\frac{E}{F_y}} = 113.432 \)

Calculate the elastic critical buckling stress: \( F_{eY} = \frac{\pi^2 E}{(K L_y / r_y)^2} = 120.668 \text{ksi} \)

Calculate the flexural buckling stress: \( F_{cY} = 0.658 \frac{F_y}{F_{eY}} F_y = 42.039 \text{ksi} \)

Compressive strength for flexural buckling along Y: \( \phi_c P_{nBY} = \phi_c F_{cY} A_g = 1, 002.625 \text{kips} \)

Ratio for flexural buckling strength = 0.838

---

**V. Shear**

V. AISC 360-16 Shear Strong Axis

Verify the shear strength of an I section loaded in the strong axis using the LRFD and ASD methods per AISC 360-16.

**References**

**Related Links**

- D1.A.5.4 Design for Shear (on page 1373)

**Details**

From the reference:

> determine the available shear strength and adequacy of an ASTM A992 W24X62 with end shears of 48 kips from dead load and 145 kips from live load.

The shear capacity values are evaluated from AISC Manual Table 2-4 and the also calculated.

**Validation**

Area of the web used for shear is:

\[
A_w = d t_w = 23.7 \times 0.430 = 10.2 \text{ in}^2
\]

The nominal shear strength is:

\[
V_n = 0.6 F_y A_w C_v = 0.6 (50)(10.2)(1.0) = 306 \text{ kips}
\]

**LRFD**

The shear strength is:

\[
\phi V_n = 1.00(306) = 306 \text{ kips}
\]

The ultimate shear demand is:
\[ Vu = 1.2 \times (48) + 1.6 \times (145) = 289.6 \text{ kips} \]

**ASD**

The allowable shear is:

\[ V_n / Q_v = 306 / 1.5 = 204 \text{ kips} \]

The shear demand is:

\[ V_a = 48 + 145 = 193 \text{ kips} \]

**Results**

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being \( \text{about} \) the relevant axis (X/Y), while the results for shear are reported as being for shear forces \( \text{along} \) the axis.
   E.g: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 Shear Weak Axis

Verify the shear strength of an I section loaded in the weak axis using the LRFD and ASD methods per AISC 360-16.

References

Related Links

- D1.A.5.4 Design for Shear (on page 1373)

Details

From the reference:

Verify the available shear strength and adequacy of an ASTM A992 W21X48 beam with end shears of 20.0 kips from dead load and 60.0 kips from live load in the weak direction.

Validation

---
\( C_{v2} = 1.0 \) for all ASTM A6 W shapes with \( F_y \leq 70 \) ksi, per the User Note in section G6 of the AISC 360-16 specification.

The nominal shear strength is:
\[
V_n = 2 \times [0.6 F_y b ti C_{v2}] = 2 \times [0.6 (50)(8.14)(0.43)(1.0)] = 210.0 \text{ kips}
\]

**LRFD**

The shear strength is:
\[
\phi V_n = 0.90(210.0) = 189.0 \text{ kips}
\]

The ultimate shear demand is:
\[
V_u = 1.2 (20) + 1.6 (60) = 120 \text{ kips}
\]

**ASD**

The allowable shear is:
\[
V_n / \Omega_v = 306 / 1.67 = 125.8 \text{ kips}
\]

The shear demand is:
\[
V_a = 20 + 60 = 80 \text{ kips}
\]

**Results**

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.

2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.

3. Bending results are reported as being ⪫ about ⪫ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ⪫ along ⪫ the axis.

E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

**V. Tension**

V. AISC 360-16 I Tension LRFD

To verify the tensile yield strength of an I section using the LRFD method from the AISC 360-16 code.

**Reference**

**Details**

Verify the tensile yield and tensile rupture strength of an I section (W8X21) using the LRFD method. The material is A992 ($F_y = 50$ ksi, $F_u = 65$ ksi)

The area of the bolt holes is assumed to be zero. A known shear lag factor of 0.908 is directly specified.

The length of the member is 25 ft. It is loaded axial in tension with a dead load of 30 kips and a live load of 90 kips.

**Validation**

The factored axial load, $P_u = 1.2 \times 30 + 1.6 \times 90 = 180$ kips

**Tensile Yield Strength**

The tensile yield strength: $\phi_{tY}P_{nY} = \phi_{tY} \times F_y \times A_g = 0.9 \times 50 \times 6.16 = 277.2$ kips

Ratio for yield strength: 0.649

**Tensile Rupture Strength**

For this example, $A_n$ is assumed equal to $A_g$.

Effective area, $A_e = A_n \times U = 6.16 \times 0.908 = 5.593$ in$^2$

The tensile rupture strength = $\phi_{tR}P_{nR} = \phi_{tR} \times F_u \times A_e = 0.75 \times 65 \times 5.593 = 272.672$ kips

Ratio for rupture strength: 0.660

**Results**

V. Torsion

V. AISC 360-16 - Torsion

Verify the torsional strength of an angle section using the LRFD method in the AISC 360-16 code. Use the simple method for calculating torsional shears (i.e., no full twist analysis). Perform torsion checks per AISC Design Guide 9.

Reference
2. Torsional Analysis of Structural Steel Members Design Guide 9, American Institute of Steel Construction

Details

The angle section is an L 3x3x1/2 angle of ASTM A992 material. The member is a 2 ft long cantilever with a total end torque of 3.0 in·kips.

Validation

Maximum torsional shear stress: \( \tau_f = \frac{Tt_f}{J} = 3.0 \frac{0.5}{0.234} = 6.41 \text{ksi} \)

By observation, direct shear stress is zero (torsion loading only). Therefore, total torsional stress is = \( \tau_f \).

Torsional shear resistance: \( \phi T \times 0.6 \times F_y = 0.9 \times 0.6 \times 50 = 27 \text{ksi} \)

Ratio: \( 6.41 \text{ ksi} / 27 \text{ ksi} = 0.237 \)

Results

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
========================================================================
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC
360:16
design results are reported in AISC 360-16 code axis convention.
AISC Spec. STAAD.Pro Description
---------- ---------- ------------
X Z Axis typically parallel to the sections
principal major axis.
Y Y Axis typically parallel to the sections
principal minor axis.
Z               X          Longitudinal axis perpendicular to the
cross section.
SECTION FORCES AXIS MAPPING: -

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

Verification Examples

V.09 Steel Design

### V. AISC 360-10 - G-6

**Reference**

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Problem**

From the reference:

> Verify the available shear strength and adequacy of a W21×48 ASTM A992 beam with end shears of 20.0 kips from dead load and 60.0 kips from live load in the weak direction.

Refer to the reference for calculations.

**Comparison**

STAAD.PRO CODE CHECKING - ( AISC-360-10-ASD) v1.4a

ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted)
### V. AISC 360-10 - D-2

**Reference**

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Problem**

From the reference:

Verify, by both ASD and LRFD, the tensile strength of an L4×4×1/2, ASTM A36 [...]. The member carries a dead load of 20 kips and a live load of 60 kips in tension. Calculate at what length this tension member would cease to satisfy the recommended slenderness limit. Assume that connection limit states do not govern.

Refer to the reference for calculations.

**Comparison**

*Table 545: Comparison of results*

<table>
<thead>
<tr>
<th>Result Type</th>
<th>Reference</th>
<th>STAAD.Pro</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\phi_t P_n$ (kips) [LRFD]</td>
<td>122</td>
<td>122</td>
<td>none</td>
</tr>
<tr>
<td>$P_n / \Omega_t$ (kips) [ASD]</td>
<td>80.8</td>
<td>80.8</td>
<td>none</td>
</tr>
</tbody>
</table>
To calculate the length at which the member would exceed the slenderness limit of 300: (6 in)/(slenderness ratio) × 300

\[
(6 \text{ in})/(7.732) \times 300 = 232.8 \text{ in} = 19.4 \text{ ft}
\]

STAAD Input

The file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\360-2010\AISC 360-10 - D-2.STD is typically installed with the program.

Tip: You can copy and paste this content directly into a .std file to run in STAAD.Pro.

### V. AISC 360-10 - F.2-2

#### Reference

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

#### Problem

Check an C15x33.9 channel of ASTM A36 steel which serves as a roof edge beam. The simple span is 25 ft. The nominal loads on the member are a dead load 0.23 kip/ft and a uniform live load of 0.69 kip/ft. The beam is braced at fifth points and at ends.  

Refer to Example F.2-2B in the reference for calculations.

#### Comparison

**Table 546: Comparison of results**

*********** END OF THE STAAD.Pro RUN ***********

**** DATE= APR 14,2019    TIME= 23:11:32 ****

V. AISC 360-10 - H.1B

Reference

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Objective

From the reference:

Using AISC Manual tables to determine the available compressive and flexural strengths, determine if an ASTM A992 W14×99 has sufficient available strength to support the axial forces and moments listed as follows, obtained from a second-order analysis that includes P-δ effects. The unbraced length is 14 ft and the member has pinned ends. KLx = KLy = Lb = 14.0 ft.

Refer to the reference for calculations.

Note: A static analysis is used in STAAD.Pro as the reference supplies only the resulting forces from an assumed P-δ analysis.

### V. AISC 360-10 - E.5

**Reference**

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Problem**

From the reference:

Verify the strength of a 2L 4×3-1/2×3/8 LLBB (3/8-in. separation) strut, ASTM A36, with a length of 8 ft and pinned ends carrying an axial dead load of 20 kips and live load of 60 kips.

Refer to the reference for calculations.

**Notes**

STAAD.Pro does *not* perform design per Section E6 of the specification. It is assumed that sufficient intermediate connectors of an appropriate type are present. It is left to the engineer to verify the intermediate connector design.

**Comparison**

**Table 548: Comparison of results**

V.09 Steel Design

---

### V. AISC 360-10 - F.1-3B

**Reference**

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Problem**

Verify the available flexural strength of a W18x50, ASTM A992 beam. The span is 35 ft and the beam is braced at both ends and at the center. The dead load is 0.45 kip/ft and the live load is 0.75 kip/ft.

**Comparison**

**Table 549: Comparison of results**

<table>
<thead>
<tr>
<th>Result Type</th>

<td>3,460 in-kips = 288.3</td>
<td>negligible</td>
</tr>
<tr>
<td>$M_n/O_b$ (ft·kips) [ASD]</td>
<td>191</td>
<td>2,300 in-kips = 191.7</td>
<td>negligible</td>
</tr>
</tbody>
</table>

**STAAD Input**

The file `C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\360-2010\AISC 360-10 - F.STD` is typically installed with the program.

**Tip:** You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

V. AISC 360-2005

V. AISC 360-05 Bending

To verify the flexural member strength in strong-axis bending of an I section for both LRFD and ASD methods per the AISC 360-05 code.

References

Details
Verify the Flexural Member Strength in Strong-Axis Bending by both LRFD and ASD method with ASTM A992 W18X50 beam with a simple span of 35 feet. The nominal loads are a uniform dead load of 0.45 kip/ft and a uniform live load of 0.75 kip/ft. Assuming the beam is continuously braced.

Validation
ASTM A992: $F_y = 50 \text{ ksi}, F_u = 65 \text{ ksi}$
Calculate the required flexural strength:

**LRFD**

\[
w_u = 1.2(0.450 \text{ kip/ft}) + 1.6(0.750 \text{ kip/ft}) = 1.74 \text{ kip/ft}
\]

\[
M_u = \frac{1.74 \text{ kip/ft} (35.0 \text{ ft}^2)}{8} = 266 \text{ kip-ft}
\]

**ASD**

\[
w_a = 0.450 \text{ kip/ft} + 0.750 \text{ kip/ft} = 1.20 \text{ kip/ft}
\]

\[
M_a = \frac{1.20 \text{ kip/ft} (35.0 \text{ ft}^2)}{8} = 184 \text{ kip-ft}
\]

Per the User Note in section F-2 of ref 2 (p.16.1-47), the W18X50 section is compact. Since the beam is continuously braced and compact, only the yielding limit state applies.

**Tip:** Per Table 3-2 of ref. 2 (p.3-17), the W18X50 is not the most efficient shape for this individual beam. This example follows that given in ref 1. STAAD.Pro will select a lighter beam if the member selection command is used.

**LRFD**

\[
\phi_b M_n = 0.9 \times (101 \text{ in}^3 \times 50 \text{ ksi})(1 \text{ ft} /12 \text{ in}) = 379 \text{ ft kip} > 266 \text{ ft kip}
\]

**ASD**

\[
M_n/\Omega_b = M_{px}/\Omega_b = (101 \text{ in}^3 \times 50 \text{ ksi})(1 \text{ ft} /12 \text{ in}) / 1.67 = 252 \text{ ft kip} > 180 \text{ ft kip}
\]

V. AISC 360-05 Compression

Verify the axial compression capacity for a the y-y axis of an I section for both the LRFD and ASD methods per the AISC 360-05 code.

References

1. Design Examples, Version 13.0, American Institute of Steel Construction, 2005, page E-4. Example E.1a

Details

The column is 30 ft long, pinned top and bottom in both axis.
The section is an ASTM A992 (Fy = 50 ksi) W-shape column to carry an axial dead load of 140 kips and live load of 420 kips. The column is 30 feet long.

Validation

Calculate the required strength.

LRFD:

\[ P_u = 1.2(140 \text{ kips}) + 1.6(420 \text{ kips}) = 840 \text{ kips} \]

ASD:

\[ P_a = 140 \text{ kips} + 420 \text{ kips} = 560 \text{ kips} \]

For a pinned-pinned condition, \( K = 1.0 \) (Table C-C2.2 of ref. 2). Because the unbraced length is equal about both x-x and y-y directions, y-y axis buckling governs.

Use Table 4-1 in ref 2 and select a W14x132 (\( K_{Ly} = 30 \text{ ft} \)). From this table:

\[ \phi_c P_n = 892 \text{ kips} > 840 \text{ kips} \]

\[ P_n/\Omega_c = 594 \text{ kips} > 560 \text{ kips} \]

### V. AISC 360-05 Tension

Verify the tensile yield strength and tensile rupture strength of an I section using both the LRFD and ASD methods per the AISC 360-05 code.

Reference

1. Design Examples, Version 13.0, American Institute of Steel Construction, 2005, page D-2. Example D.1

Details

Verify the member Tensile Yield strength and Tensile Rupture Strength by both LRFD and ASD with the bolted end connection of a I Section (W8X21) using the LRFD and ASD method

Steel Gr. ASTM A992.
The connection consists of 2 rows of 4-3/4"Ø bolts in each flange (16 bolts total) in standard holes. The holes are spaced evenly at 3" on center, with a 1-1/4" edge to center at the end of the flange in line with the tensile force.

**Validation**

ASTM A992: $F_y = 50$ ksi, $F_u = 65$ ksi

Assume a W8X21 section:

- $A_g = 6.16$ in$^2$
- $b_f = 5.27$ in
- $t_f = 0.400$ in
- $d = 8.28$ in
- $r_y = 1.26$ in
- $y = 0.831$ in (for a WT4X10.5)

Calculate the required tensile strength.

**LRFD**

$$P_u = 1.2(30 \text{ kips}) + 1.6(90 \text{ kips}) = 180 \text{ kips}$$

**ASD**

$$P_a = 30 \text{ kips} + 90 \text{ kips} = 120 \text{ kips}$$

Check the tensile yield strength limit state using tabulated values per Table 5-1 in ref. 2:

$$\phi_t P_n = 277 \text{ kips} > 180 \text{ kips}$$

$$P_n/\Omega_t = 184 \text{ kips} > 120 \text{ kips}$$

Check the available tensile rupture strength at the end connection. The tabulated values are for $A_e/A_g \geq 0.75$. Verify this assumption is applicable.

Calculate $U$ as the larger of the values from Table D3.1 case 2 or case 7 (ref. 2).

**Case 2** - Check as two WT shapes:

$$U = 1 - x/l = 1 - 0.831 \text{ in} / 9.0 \text{ in} = 0.908$$

where

- $l =$ length of the bolted connection = 3x 3.0 in = 9.0 in
- $x =$ distance from the flange face to the plastic neutral axis. This is taken from Table 1-8 of ref. 2.

**Case 7**

$$b_f = 5.27 \text{ in} < 2/3d = 2/3(8.28 \text{ in}) = 5.52 \text{ in}; U = 0.85$$

Use $U = 0.908$

Calculate the net area at the bolted connection:

$$A_n = A_g - 4(\phi_h + 1/16 \text{ in})t_f = 6.16 \text{ in}^2 - 4(13/16 \text{ in} + 1/16 \text{ in})(0.400 \text{ in}) = 4.76 \text{ in}^2$$

Calculate the effective area:

$$A_e = A_n U = 4.76 \text{ in}^2 \times 0.908 = 4.32 \text{ in}^2$$

$$A_e/A_g = 4.32 \text{ in}^2 / 6.16 \text{ in}^2 = 0.701 < 0.75$$
Therefore, the tabulated values for rupture do not apply. Calculate the rupture strength:

\[ P_n = F_u A_e = 65 \text{ ksi (4.32 in}^2) = 281 \text{ kips} \]

LRFD

\[ \phi P_n = 0.75(281 \text{ kips}) = 211 \text{ kips} > 180 \text{ kips} \]

ASD

\[ P_n/\Omega_t = 281 \text{ kips}/2.00 = 141 \text{ kips} > 120 \text{ kips} \]

### V. Steel Design per AISC ASD

**V. AISC ASD - Column Compression Capacity 1**

Determine the axial compression capacity of a W14X132 column.

**Reference**

**Problem**

\[ F_y = 36 \text{ ksi} \]
Comparison

The reported STAAD.Pro value is obtained by multiplying $FA$ times $AX$ from the STAAD.Pro output:

$$17.36 \text{ ksi (38.8 in}^2) = 673.6 \text{ kips}$$

<table>

```
**V. AISC ASD - Tee Compression Capacity**

Determine the axial compression capacity of a WT10.5x25.

**Reference**

**Problem**

\[ F_y = 36 \text{ ksi} \]
\[ K_y L_y = 5 \text{ ft} \]
\[ K_z L_z = 30 \text{ ft} \]

**Comparison**

The reported STAAD.Pro value is obtained by multiplying \( FA \) times \( AX \) from the STAAD.Pro output \( = 10.09(7.35) = 74.16 \).

V. AISC ASD - 2D Frame Validation

Determine the allowable stresses (per 1989 AISC code) for the members of the structure as shown in the figure. Also, perform a code check for these members based on the results of the analysis.

Reference

Problem

Members 1, 2 = W12X26, Members 3, 4 = W14X43
Members 5, 6, 7 = W16X36, Memb 8= L40404, Memb 9 = L50506

F = 15 kip (wind load)
w = 2 kip/ft (dead load + live load)
Steel: Fy = 36ksi

Hand Calculation

Member 1
Size W12x26, L = 10 ft., a = 7.65 in², Sz = 33.39 in³
Per Section F2 is the lower value for the yielding and lateral-torsional buckling limit states:
Mₙ = Mₚ = FᵧZₓ = 36ksi × 37.2 in³ = 1,339 in·k = 111.3 ft·k

\[
L_p = 1.76r_y\sqrt{\frac{E}{F_y}} = 1.76\left(1.51\text{in}\right)\sqrt{\frac{29,000\text{ksi}}{36\text{ksi}}} = 75.4\text{in}
\]

From observation Load case 1 will govern,
Fₓ = 25.0 kip (compression), Mₓ = 56.5 ft·kip
Area of compressive flange = 6.49*0.38 = 2.466 in²
Allowable bending stress, per Clause F1-8 (page 5-47 of Manual)
\[
f_b = 12 \cdot 1000 \cdot 1.0/[10 \cdot 12 \cdot (12.22/2.466)] = 20.1817 \text{ksi}
\]
(\(k/l/r\)ᵧ = 120/1.5038 = 79.8, so \(f_a = 15.38 \text{ksi}\)

Stresses per Table C-36 (page 3-16 of manual)
\[
f_a = F_x/7.65 = 3.268
\]
\[
f_b = 56.5 \cdot 12/33.39 = 20.31 \text{ksi}
\]
(\(k/l/r\)z = 120/5.1639 = 23.238, so \(F'_{ez} = 276.54 \text{ksi}\)

Equation H1-1, page 5-54 of Manual
\[
3.268/15.38 + 0.85 \cdot 20.31 / [(1-3.268/276.54) \cdot 20.1817] = 1.078
\]
Equation H1-2, page 5-54 of Manual.
\[
3.268/(0.6 \cdot 36) + 20.31/20.1817 = 1.1576
\]
Therefore, equation H1-2 governs and ratio = 1.1576

Member 2
Size W12x26, L = 5 ft., a = 7.65 in², Sz = 33.39 in³
From observation load case 1 will govern,
Fₓ = 8.71 kip (compression), Mₓ = 56.50 ft·kip
Since L is less than Lₜ = 6.85ft, per Clauses F1-1 & F1-2 (page 5-45 of Manual)
\[
f_b = 0.66 \cdot 36 = 23.76 \text{ksi}
\]
(\(k/l/r\)ᵧ = 60/1.5038 = 39.90, so \(f_a = 19.19 \text{ksi}\)

Per Table C-36 (page 3-16 of Manual)
\[
f_a = 8.71/7.65 = 1.1385, \ f_b = 56.5 \cdot 12/33.39 = 20.31 \text{ksi}
\]
Since \(f_a/F_a\) less than 0.15, apply equation H1-3 (page 5-54 of Manual)
\[
1.1385/19.19 + 20.31/23.76 = .0593 + .8548 = 0.9141
\]

Member 3
Size W14X43, L = 11 ft, a = 12.6 in², Sz = 62.7 in³
From observation load case 3 will govern,
\[ F_x = 25.5 \text{ kip (compression), } M_z = 112.173 \text{ ft-kip} \]
Referring to clause F1-2, page 5-45 of Manual.
\[ L_c = 8.4 \text{ ft. Therefore} \]
\[ f_b = 0.6 \cdot 36 = 21.6 \text{ ksi} \]
\[ (kI/r)y = 132/1.8941 = 69.69, \]
so \[ f_a = 16.46 \text{ ksi per Table C-36 (page 3-16 of Manual)} \]
\[ f_a = 25.5/12.6 = 2.024 \]
\[ f_b = 112.173 \cdot 12/62.66 = 21.48 \text{ ksi} \]
since \[ f_a/F_a \text{ less than 0.15, use equation H1-3, page 5-54 of Manual} \]
\[ 2.024/16.46 + 21.48/21.6 = 0.123 + 0.994 = 1.117 \]
Member 4
Size W14x43, L = 4 ft, a = 12.6 in², Sz = 62.7 in³
From observation, load case 3 will govern,
\[ F_x = 8.75 \text{ kip (tension), } M_z = 112.173 \text{ ft-kip} \]
Since L is less than \( L_c = 8.4 \text{ ft} \)
\[ f_b = 0.66 \cdot 36 = 23.76 \text{ ksi} \]
Clause F1-1 (page 5-45 of Manual)
\[ f_a = 8.75/12.6 = 0.694 \]
\[ f_b = 112.73x12/62.66 = 21.48 \text{ ksi} \]
Combined tension and bending, use equation H2-1, page 5-55 of Manual.
\[ 0.694/(0.6 \cdot 36) + 21.48/23.76 = 0.032 + 0.904 = 0.936 \]
Member 5
Size W16x36, L = 5 ft, a = 10.6 in², Sz = 56.49 in³
From observation, load case 3 will govern.
\[ F_x = 14.02 \text{ kip (compression), } M_z = 57.04 \text{ ft-kip} \]
Since L is less than \( L_c = 7.37 \text{ (per Clause F1-2, page 5-45 of Manual)} \)
\[ f_b = 0.66 \cdot 36 = 23.76 \text{ ksi} \]
\[ (kI/r)y = 60./1.52 = 39.47 \]
so \[ f_a = 19.23 \text{ ksi per Table C-36 (page 3-16 of Manual)} \]
\[ f_a = 14.02/10.6 = 1.32 \]
\[ f_b = 57.04 \cdot 12/56.5 = 12.12 \text{ ksi} \]
Since \[ f_a/F_a \text{ less than 0.15, use equation H1-3, page 5-54 of Manual} \]
1.32/19.23 + 12.12/23.76 = 0.069 + 0.510 = 0.579

Member 6
Size W16x36, L = 16 ft, a = 10.6 in², Sz = 56.49 in³
From observation, load case 1 will govern. Forces at midspan are
Fₓ = 5.65 kip (compression), Mₑ = 71.25 ft·kip
From Chapter F of the AISC ASD 9th ed. specs., with Cb = 1.0,
(102,000Cb/Fy)₁/² = 53.229
(510,000Cb/Fy)₁/² = 119.02
L/rT = 192/1.79 = 107.26
53.229 < 107.26 < 119.02
Therefore Fₑ (as per F1-6, page 5-47 of Manual)
[(2/3) – 36 · 107.26 · 107.26/(1,530,000)] · 36 = 14.25 ksi
(K/I/r)y = 192/1.5203 = 126.29
so fₓ = 9.36 per Table C-36 (page 3-16 of Manual)

fₑ = 5.65/10.6 = 0.533
fₑ = 71.25x12/56.49 = 15.14 ksi
Since fₓ/Fₓ less than 0.15 use formula [H1-3, page 5-54 of Manual]
0.533/9.36 + 15.14/14.25 = 0.057 + 1.06 = 1.119

Member 7
Size W16x36, L = 4 ft, a = 10.6 in², Sz = 56.49 in³
L₂ = 7.37 ft (Clause F1-2 page 5-45 of Manual)
From observation load case 3 will govern, Fₓ = 24.06 kip (tension), Mₑ = 62.96 ft·kip
From Clause F1-1, the allowable compressive stress is
fₑ = 0.66 Fy = 23.76 ksi
Since section is in tension, per Clause F1-5 (page 5-45 of Manual)
fₑ = 0.60 · 36 = 21.60 Ksi
Choosing the larger of above 2 values, fₑ = 23.76 Ksi
fₑ = 24.06/10.6 = 2.2698
fₑ = 62.96 · 12/56.49 = 13.37
Since combined tension and bending, use equation H 2-1, page 5-55 of the AISC ASD 9th ed. specs.
2.2698/(0.6 · 36) + 13.37(23.76) = 0.105 + 0.5627 = 0.6677

Member 8
Size L4x4x1/4, L = 7.071 ft, a = 1.94 in²
From observation load case 1 will govern, Fₓ = 23.04 kip (Comp.)
Fa is computed as per page 5-310 of the AISC ASD 9th ed. specs.

\[ Q_s = 1.34 - 0.00447 \cdot (4/0.25) \cdot (36)^{1/2} = 0.9108 \]

\[ Q_a = 1.0 \]

\[ Q = Q_s \cdot Q_a = 0.9108 \]

\[ C_c = 92.0 \cdot \pi^2 \cdot E/(Q \cdot F_y)^{1/2} = [2.0 \cdot \pi^2 \cdot 29000/(0.9108 \cdot 36)]^{1/2} = 132.1241 \]

\[ K_I/r = 7.071 \cdot 12/0.795 = 106.73 < C_c. \]

Hence, \( f_a = 11.6027 \) ksi (computed per equation 4-1)

Actual compressive stress

\[ f_a = 23.04/1.94 = 11.876 \text{ ksi} \]

Therefore, Ratio =

\[ f_a/f_a = 11.876/11.602 = 1.024 \]

Member 9

Size L5x5x3/8, \( L = 5.657 \) ft, \( a = 3.61 \text{ in}^2 \)

From observation, load case 1 governs, \( F_x = 48.44 \) kip (Comp.)

Fa is computed as per page 5-310 of the AISC ASD 9th ed. specs.

\[ Q_s = 1.34 - 0.00447 \cdot (5/0.375) \cdot (36)^{1/2} = 0.9824 \]

\[ Q_a = 1.0 \]

\[ Q = Q_s \cdot Q_a = 0.9824 \]

\[ C_c = 92.0 \cdot \pi^2 \cdot E/(Q \cdot F_y)^{1/2} = [2.0 \cdot \pi^2 \cdot 29000/(0.9824 \cdot 36)]^{1/2} = 127.2238 \]

\[ (K_I/r)_{\text{min}} = 5.657 \cdot 12/0.99 = 68.57 < C_c. \]

Hence, \( f_a = 16.301 \) ksi (computed per equation 4-1)

Actual compressive stress

\[ f_a = 48.44/3.61 = 13.418 \text{ ksi} \]

Therefore Ratio =

\[ f_a/f_a = 13.418/16.301 = 0.823 \]

STAAD.Pro 4033 User Manual
V. Steel Design per AISC LRFD

V. AISC LRFD - Wide Flange Tension Capacity

To check the adequacy of a W8X24 American section to carry a tensile design load of 245 Kips.

Reference

Hand calculation using the following reference:

Problem
Assume the reduction in area due to bolt holes to be equivalent to a net section factor of 0.72.

\[ F_y = 50 \text{ ksi} \]
\[ L = 10 \text{ ft} \]

Hand Calculation
Net section = 0.72(7.08in.\(^2\)) = 5.11 in.\(^2\)

\[ \phi P_n = \frac{\phi t F_y A_g}{\phi t F_u A_e} = \frac{0.9(50\text{ksi})(7.08\text{in.}^2)}{0.75(65\text{ksi})(5.11\text{in.}^2)} = 318.6k \]
\[ \phi P_n = \frac{0.75(65\text{ksi})(5.11\text{in.}^2)}{0.75(65\text{ksi})(5.11\text{in.}^2)} = 248.5k \]

Comparison
The reported STAAD.Pro value is based on the term PNT in the STAAD.Pro output.

Table 569: Comparison of results

</thead>
<tbody>
<tr>
<td>Design strength (kips)</td>
<td>248.5</td>
<td>248.51</td>
<td>none</td>
</tr>
</tbody>
</table>

Note: The assumed NSF of 0.72 is comparable to the term Ae/Ag which evaluates to 5.11/7.08.
V. AISC LRFD - Angle Section Tension Capacity

To check the adequacy of a L4X4X1/2 American single angle to carry a tensile design load of 120 Kips.

Reference

Hand calculation using the following reference:

Problem

Assume the reduction in area due to bolt holes to be equivalent to a net section factor of 0.795.

\[ F_y = 36 \text{ ksi} \]

Hand Calculation

Net section \( = 0.795(3.75 \text{ in.}^2) = 2.98 \text{ in.}^2 \)

\[
\phi_P = \begin{cases} 
\phi_t F_y A_g = 0.9(36 \text{ksi})(3.75 \text{in.}^2) = 121.5k \\
\phi_t F_u A_e = 0.75(58 \text{ksi})(2.98 \text{in.}^2) = 129.6k 
\end{cases}
\]
Comparison

The reported STAAD.Pro value is based on the term PNT in the STAAD.Pro output.

***************************************************************************
ALL UNITS ARE - KIP INCH (UNLESS OTHERWISE Noted)
V. AISC LRFD - Tee Section Compression Capacity

To find a suitable American T-section with an axial compressive strength of 100 Kips.

Reference

Hand calculation using the following reference:

Problem

The member ends are pinned, and the member is braced at the ends only for both axes.

\[ F_y = 50 \text{ ksi} \]

\[ \text{Length} = 20 \text{ ft} \]

Comparison

The reported STAAD.Pro value is based on the term PNC in the STAAD.Pro output.

**Table 574: Comparison of results**

V. AISC LRFD - Rectangular HSS Compression Strength

To validate that an American ASTM A500 grade B HSS12X10X1/2 compression member has a design compressive strength of over 500 kips.

Reference

Hand calculation using the following reference:

_AISC Load Factor Resistance Design, 3rd Edition, Example 4.8, page 4-13 & Table 4-6, Page 4-50._

Problem

\[ F_y = 46 \text{ ksi} \]

\[ \text{Length} = 20 \text{ ft} \]
KY = KZ = 0.8

Comparison

The reported STAAD.Pro value is based on the term PNC in the STAAD.Pro output.

Table 575: Comparison of results

<table>
<thead>
<tr>
<th>Result Type</th>
<th>Theory</th>
<th>STAAD.Pro</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design strength in Axial Compression (kips)</td>
<td>634 (*)</td>
<td>634.26</td>
<td>none</td>
</tr>
</tbody>
</table>

Note: *In the solved example, on page 4-14, the capacity is reported as ϕ×Pn = 580 kips. Looking at Table 4-6 on page 4-50, this happens to be the capacity for a 20 ft effective length, not a 16 ft effective length. As per the table, the capacity corresponding to a 16 ft effective length is 634 kips.

STAAD Input

The file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\LRFD 3rd Edition\AISC LRFD - Rectangular HSS Compression Strength.STD is typically installed with the program.

V. AISC LRFD - Wide Flange Flexural Strength 1

To determine the design flexural strength of an ASTM A992 W18X40 bent about its strong axis on a 35-ft span with a uniformly distributed load.

Reference

Hand calculation using the following reference:

*AISC Load Factor Resistance Design*, 3rd Edition, Example 5.1, Case (a), page 5-12.

Problem

The beam is braced such that $L_b = 2\ ft$. The deflection at mid-span due to a uniformly distributed service load of 1 kip/ft is also to be calculated.

$F_y = 50\ ksi$

$Length = 35\ ft$

Comparison

The reported STAAD.Pro value is based on the term $MNZ$ in the STAAD.Pro output.

V. AISC LRFD - Wide Flange Flexural Strength 3

To determine the design flexural strength of an ASTM A992 W18X40 bent about its strong axis on a 35-ft span with a uniformly distributed load.

Reference

Hand calculation using the following reference:

AISC Load Factor Resistance Design, 3rd Edition, Example 5.1, Case (c), page 5-12.

Problem

The beam is braced at the ends and so, $L_b = 35 \text{ ft}$.

$F_y = 50 \text{ ksi}$

Length = 35 ft

Comparison

The reported STAAD.Pro value is based on the term $MNZ$ in the STAAD.Pro output.

Table 580: Comparison of results

<table>
<thead>
<tr>
<th>Result Type</th>

V. AISC LRFD - Non Compact Wide Flange 1

To check the adequacy of a non-compact fully braced W shape to carry a uniformly distributed load of 5.5 kips/ft.

Reference

Problem

W14x90 shape. Beam is bent about its strong axis.

\[ F_y = 50 \text{ ksi} \]
\[ \text{Length} = 30 \text{ ft} \]

Hand Calculation

\[ M_N = 6,910 \text{ in} \cdot \text{kips} = wL^2/8 \]
\[ w = \frac{8M}{L^2} = \frac{8(6,910)}{(30 \cdot 12)^2} = 0.427 \text{kips/in} \]
\[ W = 0.427 \text{kips/in}(30 \text{ft})(12 \text{ in/ft}) = 153.6 \text{kips} \]
\[ \phi_b W_c = 153.6 \text{kips} (30 \text{ ft}) = 4,607 \text{ ft kips} \]

Comparison

The reported STAAD.Pro value is based on the term MNZ in the STAAD.Pro output.

V. AISC LRFD - Channel Shape Capacity

To check the adequacy of a fully braced C shape to carry a uniformly distributed load of 1.5 kips/ft.

Reference

*AISC Load Factor Resistance Design*, 3rd Edition, Table 5.9, page 5-120.

Problem

C12x25 shape. Beam is bent about its strong axis.

\[ F_y = 50 \text{ ksi} \]

Length = 20 ft

Hand Calculation

\[ MNZ = 952.6 \text{ in·kips} = \frac{wL^2}{8} \]
\[ w = \frac{8M}{l^2} = \frac{8(952.6)}{(20 \cdot 12)^2} = 0.132 \text{kips/in} \]

\[ W = 0.132 \text{kips/in}(20\text{ft})(12 \text{ in/ft}) = 31.8 \text{kips} \]

\[ \phi_b W_c = 31.8 \text{kips} (20 \text{ ft}) = 635.1 \text{ ft-kips} \]

Comparison

The reported STAAD.Pro value is based on the term MNZ in the STAAD.Pro output.

V. AISC LRFD - MC Shape Capacity

To check the adequacy of a fully braced MC shape to carry a uniformly distributed load of 1.34 kips/ft.

Reference

Problem
MC10x41.1 shape. Beam is bent about its strong axis.

\[
F_y = 50 \text{ ksi} \\
\text{Length} = 25 \text{ ft}
\]

Hand Calculation

\[
MNZ = 1,273 \text{ in} \cdot \text{kips} = \frac{wl^2}{8}
\]

\[
w = \frac{8M}{l^2} = \frac{8(1,273)}{(25 \cdot 12)^2} = 0.113 \text{kips/in}
\]

\[
W = 0.113 \text{kips/in}(25 \text{in})(12 \text{ in/ft}) = 33.9 \text{kips}
\]

\[
\phi_b W_c = 33.9 \text{kips}(25 \text{ft}) = 849 \text{ ft kips}
\]

Comparison

The reported STAAD.Pro value is based on the term MNZ in the STAAD.Pro output.

V. AISC LRFD - Select Wide Flange 2

To find the optimum W shape with a flexural design strength of 150 ft-kips. Beam is braced at ends and at mid-span point.

Reference

Problem

The beam should also satisfy a deflection limit of 1.0 inches under service load.

\[ F_y = 50 \text{ ksi} \]
\[ \text{Length} = 20 \text{ ft} \]
\[ L_b = 10 \text{ ft} \]

Service load of 2.0 kip/ft. Deflection limit under service load = 1.0 in.

Comparison

The reported STAAD.Pro value is based on the term MNZ in the STAAD.Pro output.

V. AISC LRFD - Tension and Strong Axis Bending

To check the adequacy of an ASTM A992 W10X22 subject to axial tension and flexure about the strong axis.

Reference

Problem

W10x22 section.

\[ F_y = 50 \text{ ksi} \]
\[ F_u = 65 \text{ ksi} \]
\[ P_u = 55 \text{ kips} \]
\[ M_{uy} = 0, M_{uz} = 55 \text{ ft·kips} \]
\[ L_b = 4 \text{ ft} \]

Comparison

The reported STAAD.Pro value is based on the terms PNT and MNZ in the STAAD.Pro output.

V. AISC LRFD - Compression and Biaxial Bending

To check the adequacy of an ASTM A992 W14X176 beam subject to axial compression and biaxial bending.

Reference

Problem

W14x176 section.

\[ F_y = 50 \text{ ksi} \]
\[ P_u = 1,400 \text{ kips} \]
\[ M_{uy} = 70 \text{ ft·kips}, M_{uz} = 200 \text{ ft·kips} \]
\[ L_b = 14 \text{ ft} \]

Reverse curvature bending with equal end moments for both axis.

Hand Calculations
According to page 16.1 - 97 of the LRFD 3rd ed. code,

\[ M_p = F_y \cdot Z \leq 1.5F_y \cdot S \]

For a W14x176,

\[ 0.9 (1.5F_y \cdot S) = 0.9 [1.5 (50)(107)] = 7,222 \text{ kip-in} = 601.8 \text{ kip-ft}, \]

which is lower than \((0.9 F_y \cdot Z) = 611\). Hence, STAAD.Pro uses this limit state.

**Comparison**

The reported STAAD.Pro value is based on the terms PNC, MNY, and MNZ in the STAAD.Pro output.

V.AISC N690

V.AISC N690 1994

V. AISC N690 1994 Angle
Verify the allowable stress and critical ratio of the brace members in a frame using the AISC N690 1994 code.

Details

The horizontal load is 7.5 kips and the vertical load is 10 kips.

The forces due to loading in member 6 is 2.861 kips (tension) and in member 7 is 7.328 kips (compression).

Members 6 and 7 are "truss" members (axial-only).

Both member 6 and 7 are L 80x60x10, austenitic stainless steel ($F_y = 36$ ksi, $F_u = 58$ ksi).

Assume a net section factor of 0.9 and an effective length factor of 0.85.

Validation

\[ L = \sqrt{5^2 + 6^2}(12\text{in/ft}) = 93.726\text{in} \]

Slenderness ratio (same for both members) using the minimum value of \( r \):

For member 6, \( kL/r_2 = 0.85(93.726)/1.29 = 61.76 \)

For member 7, \( kL/r_2 = 61.76 < 300 \)

For member 7, \( kL/r_2 = 61.76 < 200 \)
For members in compression (member 7), the equivalent slenderness ratio per Eqn. 4-4 of AISC ASD p5-311 must also be determined:

\[(KL/r)_{\text{equiv}} = \pi \times \sqrt{(E/F_e)}\]

where \(F_e = \) the elastic buckling strength for flexural torsional buckling taken to be 60.348 ksi. This is defined as the lowest root of the Eqn in AISC ASD (C4-2) page 5-317.

Thus, \((KL/r)_{\text{equiv}} = \pi \times \sqrt{(29,000/60.348)} = 68.86\)

**Axial Tension: Member 6**

Actual tensile stress (gross) = \(P/A = 2.862 / 8.41 = 0.340\) ksi

Allowable tensile stress (Tension capacity) = \(0.6 \times F_y = 0.6 \times 36 = 21.6\) ksi

Critical ratio = \(0.340/21.6 = 0.016\)

**Axial Compression: Member 7**

Actual compressive stress = \(P/A = 7.328 / 8.41 = 0.871\) ksi

As this member is made from austenitic stainless steel the allowable compression stress should be determined according to clause Q.1.5.9. As \(KL/r < 120\), then the value of allowable axial stress, \(F_a\), is determined from Eqn. Q1.5-11:

\[F_a = \frac{F_y}{2.15} \cdot \left(\frac{F_y}{2.15} \cdot \frac{6}{120}\right) \times KL \bigg| r = 16.74 \cdot \left(\frac{16.71 \cdot 6}{120}\right) 68.86 = 10.57\) ksi

Check cross-section meets requirements of Q1.9, which sets a limit for any unstiffened element clause Q1.9.1.2 of \(75/\sqrt{(F_y)} = 12.67\).

- Short leg = \(B/t = 6/0.625 = 9.5 < 12.67\), OK
- Long leg = \(D/t = 8/0.625 = 12.8 > 12.67\), leg is slender

Since \(75/\sqrt{(F_y)} = 12.67 < D/t = 12.8 < 155/\sqrt{(F_y)} = 25.83\), \(Q_s\) is determined by Eqn. QC2-1:

\[Q_s = 1.340 \times 0.00447 \times (b/t) \times \sqrt{(F_y)} = 0.9967\]

Allowable compressive stress, \(F_a = 0.9967 \times 10.57 = 10.54\) ksi

Critical ratio = \(0.871 / 10.54 = 0.083\)

### V. AISC N690 1994 Channel
Verify the design of channel section used for a beam member using the AISC N690 1994 code.

#### Details
The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.

#### Validation
- **Maximum shear force (at fixed end):** \( V = 51.375 \text{ kips} \) (taken from STAAD.Pro analysis)
- **Maximum moment (at fixed end):** \( M = 830.0 \text{ in-kip} \) (taken from STAAD.Pro analysis)

#### Slenderness Ratio
- **About z-axis:** \( (KL/r)_z = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95 \)
- **About y-axis:** \( (KL/r)_y = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61 \)
Max. slenderness ratio < 300, OK.

Bending About Major Axis (Z Axis)

\[
\frac{b_f}{t_f} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83
\]

The laterally unsupported length of the compression flange, \( L_b = 80 < \frac{76b_f}{\sqrt{F_y}} = 120 \)

and \( \frac{20,000}{(d/A_f) F_y} = 89.56 \)

As \( b_f/t_f \) is not in the range of \( 65/\sqrt{(F_y)} \) and \( 95/\sqrt{(F_y)} \), the value of allowable bending compressive and tensile stress \( F_{bty} = F_{bcy} = 0.6 \times F_y = 21.6 \text{ ksi} \)

Actual bending stress:

Bending Tensile Stress = bending compressive stress \( f_{btz} = f_{bcz} = MzD / (2I_z) = 15.4 \text{ ksi} \)

\[
830.0 (15.0) / (2 \times 404) = 15.41 \text{ ksi}
\]

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

Shear

Actual shear:

\[
F_y = 51.375 \text{ kips}
\]

STAAD.Pro calculates the shear are based on the general shear stress equation, \( \tau = V \times Q / (I \times t) \) from Timoshenko. Thus the shear area, \( A_y = I \times t / Q = 8.47 \text{ in}^2 \)

\[
f_v = 51.375 / 8.47 = 6.07 \text{ ksi}
\]

Allowable shear:

\( a = \) clear distance between transverse stiffeners (here taken as length) = 80 in

\( h = \) clear distance flanges of the girder = \( D - 2t_f = 14.35 \text{ in} \)

Thus, \( a/h = 5.57 \), Therefore, \( k = 5.34 + [4.00 / (a/h)^2] = 5.46 \)

\[
t = t_w = 0.72 \text{ in}
\]

If

\[
C_v = 17.2
\]

\[
F_v = \begin{cases} 
F_y / 2.89 \times C_v = 25.6 \text{ ksi} \\
0.4 \times F_y = 14.4 \text{ ksi}
\end{cases}
\]

Hence allowable = 14.4 ksi

Therefore, Ratio = \( f_v / F_v = 6.07 / 14.4 = 0.422 \)

V. AISC N690 1994 Pipe
Verify the design of a pipe section used for a beam member per the AISC N690 1994 code.

Details
The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force, \( V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \)

Maximum moment, \( M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \)

Slenderness ratio = \( (KL/r) = 9.72 < 300 \)

Bending About Major Axis (Z-Axis)
Section is compact: \( \frac{OD}{t} = 36.43 < \frac{3}{300} \frac{F_y}{F} = 91.67 \)

Allowable bending stress: \( F_b = 0.66 \times F_y = 23.76 \text{ksi} \)

Actual bending stress: \( f_{bz} = f_{bcz} = \frac{M_z}{T_z} \left( \frac{OD}{2} \right) = \frac{331.25}{262} \left( \frac{12.75}{2} \right) = 8.06 \text{ksi} \)

Stress ratio: 0.339

Shear
From the reference, the shear area:
\[
A_y = \frac{0.25n(r_2^4 - r_1^4)^2(r_2 - r_1)}{2^3(r_2^3 - r_1^3)}
\]
where
\[ r_1 = \text{inner radius} \]
\[ r_2 = \text{outer radius} \]

Shear area: \( A_y = 6.8 \text{ in}^2 \)

Actual shear stress (at supports): \( f_v = \frac{25.75}{6.8} = 3.78 \text{ ksi} \)

Actual shear stress (at midspan): \( f_v = \frac{0.75}{6.8} = 0.110 \text{ ksi} \)

Allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Stress ratio: \( 3.78/14.4 = 0.263 \)

### Verification Examples

**V.09 Steel Design**

**Verification Examples**

**V. AISC N690 1994 W Shaped**
Verify the design of a wide-flange section used for a cantilever beam using the AISC N690 1994 code.

### Details

The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.

The member is a W16X40 section with Grade A36 steel.

### Validation

Maximum shear force (constant shear): \( V = 12.5 \text{ kips} \)

Maximum moment (at fixed end): \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1,500 \text{ in} \cdot \text{kips} \)

**Slenderness Ratio**

\((KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 18.11\)

\((KL/r)_y = \text{Slenderness Ratio along Y-Axis} = 76.68\)

Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

### Bending

Allowable Bending Stress About Major Axis (Z Axis)

</tr>
<tr>
<td><strong>FX</strong></td>
</tr>
<tr>
<td>PASS</td>
</tr>
<tr>
<td>0.00 T</td>
</tr>
</tbody>
</table>

**STAAD.Pro** 4099 **User Manual**
Thus, allowable bending tensile stress \( F_{btz} = 0.66 \times F_y = 23.76 \text{ ksi} \)

**Actual bending stress About Major Axis**

\[
f_{btz} = \frac{M_z D}{2I_z} = 23.2 \text{ ksi}
\]

Stress ratio = 23.2 ksi / 23.76 ksi = 0.975

**Shear**

**Allowable Shear Stress**

\[
a = \text{clear distance between transverse stiffeners (here taken as length)} = 120 \text{ inch}
\]

\[
h = \text{clear distance flanges of the girder} = D-2t_f = 14.91 \text{ inch}
\]

Thus, \( a/h = 8.05 \), Therefore, \( k = 5.34 + \left[ \frac{4.00}{(a/h)^2} \right] = 5.36 \)

\[
t = t_w = 0.3 \text{ inch}
\]

\[
C_v = 1.475
\]

\[
F_v = \frac{F_y}{2.89} C_v \geq 0.4 \times F_y = 14.4 \text{ ksi}
\]

Hence allowable = 14.4 ksi

**Actual Shear Stress**

STAAD.Pro calculates the shear are based on the general shear stress equation, \( \tau = \frac{V \times Q}{I \times t} \) from Timoshenko. Thus the shear area, \( A_y = I \times t/Q = 4.401 \text{ in}^2 \)

\[
\tau = F_y/A_y = 12.5 \text{ kip} / 4.401 = 2.84 \text{ ksi}
\]

Stress ratio = \( \frac{\tau}{F_v} = 0.18 \)

**Results**

**V.AISC N690 1984**

V. AISC N690 1984 Angle

Verify the allowable stress and critical ratio of the brace members in a frame using the AISC N690 1984 code.

**Details**

The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are “truss” members (axial-only).
Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36$ ksi, $F_u = 58$ ksi).

Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

Validation

\[ L = \sqrt{5^2 + 6^2} \text{(12in/ft)} = 93.726 \text{in} \]

Slenderness ratio (same for both members) using the minimum value of \( r \):

\[ kL/r_z = 0.85(93.726) / 1.29 = 61.76 \]

For member 6, $kL/r_z = 61.76 < 300$

For member 7, $kL/r_z = 61.76 < 200$

**Axial Tension: Member 6**

Corrected area, $A_c = C_t \times A_x = 7.57 \text{ in}^2$

Actual tensile stress $= P/A = 2,666.18 / 7.57 = 352.2 \text{ psi}$

Allowable tensile stress (Tension capacity) $= 0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ ksi}$

Critical ratio $= 352.2 / 21600 = 0.016$

**Axial Compression: Member 7**

Actual compressive stress $= P/A = 7,104.23 / 8.41 = 844.74 \text{ psi}$

\[ C_c' = \sqrt{\frac{2n^2E}{Q_s Q_a F_y}} = 126.2 \]

\( kL/r \)min $< C_c'$, allowable compression stress, $F_a = 17.2 \text{ ksi}$

Critical ratio $= 844.74 / 17,200 = 0.049$

V. AISC N690 1984 Channel
Verify the design of channel section used for a beam member using the AISC N690 1984 code.

Details
The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.
The member is C15x50 channel section with Grade A36 steel.

Validation

Maximum shear force (at fixed end): $V = 51.375$ kips (taken from STAAD.Pro analysis)

Maximum moment (at fixed end): $M = 830.0$ in-kip (taken from STAAD.Pro analysis)

Slenderness Ratio

About $z$-axis: $(KL/r)_z = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95$

About $y$-axis: $(KL/r)_y = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61$

Max. slenderness ratio < 300, OK.

Bending About Major Axis (Z Axis)

$$\frac{b_f}{t_f} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83$$

The laterally unsupported length of the compression flange, $L_b = 80 < \frac{76b_f}{\sqrt{F_y}} = 120$

and $< \frac{20,000}{(d / A_f)F_y} = 89.56$

As $b_f/t_f$ is not in the range of $65 / \sqrt{(F_y)}$ and $95 / \sqrt{(F_y)}$, the value of allowable bending compressive and tensile stress is $F_{bty} = F_{bco} = 0.6 \times F_y = 21.6$ ksi

Actual bending stress:

Bending Tensile Stress = bending compressive stress $= f_{btz} = f_{bcz} = MzD / (2I) = 15.4$ ksi

$$830.0 \times (15.0) / (2 \times 404) = 15.41 \text{ ksi}$$

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

Shear

Actual shear:

$$F_y = 51.375 \text{ kips}$$

$$V_y = D \times t_w = 10.8 \text{ in}^2$$

$$f_{v,y} = F_y/V_y = 4.76 \text{ ksi}$$

Allowable shear:

$$a = \text{clear distance between transverse stiffeners (here taken as length)} = 80 \text{ in}$$

$$h = \text{clear distance flanges of the girder} = D-2t_f = 14.35 \text{ in}$$

Thus, $a/h = 5.57$, Therefore, $k = 5.34 + [4.00/ (a/h)^2] = 5.46$

$$t = t_w = 0.72 \text{ inch}$$

$$C_v = 17.2$$

$$F_v = (F_y/2.89)C_v \geq 0.4 \times F_y = 14.4 \text{ ksi}$$

Hence allowable = 14.4 ksi

Therefore, Ratio $= f_{v}/F_v = 0.330$

**STAAD.Pro**

4110

**User Manual**
Verify the design of a pipe section used for a beam member per the AISC N690 1984 code.

Reference

Details
The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force, \( V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \)

Maximum moment, \( M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \)

Slenderness ratio = \( (KL/r) = 9.72 < 300 \)

Bending About Major Axis (Z-Axis)
Section is compact: $\frac{OD}{t} = 36.43 < \frac{3,300}{F_y} = 91.67$

Allowable bending stress: $F_b = 0.66 \times F_y = 23.76 \text{ ksi}$

Actual bending stress:

$$f_{btz} = f_{bcz} = \frac{M_z}{I_z} \left(\frac{OD}{2}\right) = \frac{331.25}{262} \left(\frac{12.75}{2}\right) = 8.06 \text{ ksi}$$

Stress ratio: 0.339

**Shear**

From the reference, the shear area:

$$A_y = \frac{0.25n(r_2^4 - r_1^4)}{2(r_2^3 - r_1^3)}$$

where

- $r_1$ = inner radius
- $r_2$ = outer radius

Shear area: $A_y = 6.8 \text{ in}^2$

Actual shear stress (at supports): $f_v = 25.75 / 6.8 = 3.78 \text{ ksi}$

Actual shear stress (at midspan): $f_v = 0.75 / 6.8 = 0.110 \text{ ksi}$

Allowable shear stress, $F_v = 0.4 \times F_y = 14.4 \text{ ksi}$

Stress ratio: $3.78 / 14.4 = 0.263$

V. AISC N690 1984 Tee
Verify the design of a pipe section used for a beam member per the AISC N690 1984 code.

Details
A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation
Maximum shear force (at support) \( V = wL + P = (1 \text{ kip/in}) \times 60 \text{ in} + 2 \text{ kip} = 62 \text{ kips} \)

Maximum moment (at support) \( M = 0.5 \times w \times L^2 + P \times L = 0.5 (1 \text{ kip/in}) \times (60 \text{ in})^2 + (2 \text{ kip}) \times (60 \text{ in}) = 1,920 \text{ in kips} \)

Slenderness Ratio
Slenderness Ratio along Z-Axis \( (KL/r)_z = 21.22 \)
Slenderness Ratio along Y-Axis \( (KL/r)_y = 50.53 \)
Maximum Slenderness Ratio \( 50.53 < 300 \)

Bending
Allowable Bending Stress About Major Axis (Z Axis)
\[
b \frac{d}{2t} = 4.65 > 65/\sqrt{(F_Y)} = 10.833 \\
d/t_w = 28.3 < 640/\sqrt{(F_Y)} = 106.67
\]

Thus allowable bending stress is obtained by treating the section as compact.
\( F_b = 0.66 \times F_Y = 23.8 \text{ ksi} \)

Actual Bending Stress
Bending Tensile Stress \( f_{bz} = (Mz/Iz) \times Y_{bar} = 14.93 \text{ ksi} < 23.8 \text{ ksi} \)
Bending Compressive Stress \( f_{bcz} = 38.7 \text{ ksi} > 23.8 \text{ ksi} \)
Critical stress ratio \( = 38.7 \text{ ksi} / 23.8 \text{ ksi} = 1.626 \)

Shear
Allowable Shear Stress
\( a = \text{clear distance between transverse stiffeners (here taken as length)} = 60 \text{ in} \)
h = clear distance flanges of the girder = D-t = 17.01 in
Thus, a/h = 3.527 Therefore, \( k = 5.34 + \left[ \frac{4.00}{(a/h)^2} \right] = 5.65 \)
\[ t = t_w = 0.44 \text{ inch} \]
If \( C_v > 0.8 \), \( C_v = \left[ \frac{190}{(h/t)} \right] \sqrt{\frac{k}{S_y}} = 78.4 \) which is true. Thus, the value of \( C_v \) is taken as 78.4
Allowable shear stress = \( F_v = \left( \frac{F_y}{2.89} \right) C_v \leq 0.4F_y = 14.4 \text{ ksi} \)
Hence allowable shear =14.4 ksi
Actual Shear
\[ V_y = D t_w = 10.68 \text{ in}^2 \]
\[ f_v = \frac{F_y}{V_y} = 5.805 \text{ ksi} \]
Stress ratio = \( f_v/F_y = 0.403 \)
Allowable bending stress about minor axis, \( f_{btz} = 0.75 \times F_y = 27 \text{ ksi} \)

V. AISC N690 1984 W Shaped
Verify the design of a wide-flange section used for a cantilever beam using the AISC N690 1984 code.

Details
The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.
The member is a W16X40 section with Grade A36 steel.

Validation
Maximum shear force (constant shear): \( V = 12.5 \text{ kips} \)
Maximum moment (at fixed end): \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1500 \text{ in} \cdot \text{kips} \)

Slenderness Ratio
\[(KL/r)_{z} = \text{Slenderness Ratio along Z-Axis} = 18.11\]
\[(KL/r)_{y} = \text{Slenderness Ratio along Y-Axis} = 76.68\]
Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

Bending
Allowable Bending Stress About Major Axis (Z Axis)
\[\phi_{b}2t_{f} = 6.862 < 65/\sqrt{F_{y}}\]
Thus, allowable bending tensile stress \( F_{btz} = 0.66 \times F_{y} = 23.76 \text{ ksi} \)
Actual bending stress About Major Axis
\[f_{btz} = M_{z}D / 2 \times I_{z} = 23.2 \text{ ksi}\]
Stress ratio = 23.2 ksi / 23.76 ksi = 0.975

Shear
Allowable Shear Stress
\[F_{v} = 0.4 \times F_{y} = 14.4 \text{ ksi}\]
Actual Shear Stress
\[V_{y} = D \times t_{w} = 4.8 \text{ in}^{2}\]
\[f_{v} = F_{y}/V_{y} = 2.6 \text{ ksi}\]
Stress ratio = \( f_{v}/F_{v} = 0.18\)

V. ASME NF 3000 Codes

V. NF 3000-1974

V. ASME NF 3000 1974 Angle

Verify the allowable stress and critical ratio of the brace members in a frame using the ASME NF 3000 1974 code.

Details

The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are “truss” members (axial-only).
Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36$ ksi, $F_u = 58$ ksi).
Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

Validation

\[ L = \sqrt{5^2 + 6^2} \text{in/ft} = 93.726 \text{in} \]

Slenderness ratio (same for both members) using the minimum value of \( r \):

\[ kL/r_z = 0.85(93.726)/1.29 = 61.76 \]

For member 6, \( kL/r_z = 61.76 < 300 \)

For member 7, \( kL/r_z = 61.76 < 200 \)

**Axial Tension: Member 6 (per NF-74.2211)**

Corrected area, \( A_c = C_t \times A_x = 7.57 \text{ in}^2 \)

Actual tensile stress \( = P/A = 2,666.18 / 7.57 = 352.2 \text{ psi} \)

Allowable tensile stress (Tension capacity) \( = 0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ ksi} \)

Critical ratio \( = 352.2/21,600 = 0.016 \)

**Axial Compression: Member 7 (NF-74.2213):**

Actual compressive stress \( = P/A = 7,104.23 / 8.41 = 844.74 \text{ psi} \)

\[ C_c' = \sqrt{\frac{2n^2E}{Q_s Q_a F_y}} = 126.2 \quad \text{(NF-3322.2(e)(5))} \]

\( (kL/r)_{min} < C_c', \) allowable compression stress, \( F_a = 17.2 \text{ ksi} \)

Critical ratio \( = 844.74 / 17,200 = 0.049 \)

### ACTUAL STRESSES: (UNIT - POUND INCH)
V. ASME NF 3000 1974 Channel

Verify the design of channel section used for a beam member using the ASME NF 3000 1974 code.

Details

The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.
Validation

Maximum shear force (at fixed end): \( V = 51.375 \) kips (taken from STAAD.Pro analysis)
Maximum moment (at fixed end): \( M = 830.0 \) in-kip (taken from STAAD.Pro analysis)

**Slenderness Ratio**

About \( z \)-axis: \( \frac{(KL/r)_{z}}{z} = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95 \)
About \( y \)-axis: \( \frac{(KL/r)_{y}}{y} = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61 \)
Max. slenderness ratio < 300, OK.

**Bending About Major Axis (Z Axis)**

\[
\frac{b_{f}}{t_{f}} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83
\]

The laterally unsupported length of the compression flange, \( L_{b} = 80 \) < \( \frac{76b_{f}}{\sqrt{F_y}} = 120 \)

and \( < \frac{20,000}{(d/A_f)F_y} = 89.56 \)

As \( b_{f}/t_{f} \) is not in the range of \( 65/\sqrt{(F_y)} \) and \( 95/\sqrt{(F_y)} \), the value of allowable bending compressive and tensile stress \( F_{by} = F_{bcy} = 0.6\times F_y = 21.6 \text{ ksi} \)

Actual bending stress:

**Bending Tensile Stress** = bending compressive stress = \( f_{btz} = f_{bcz} = \frac{MzD}{(2I_{z})} = 15.4 \text{ ksi} \)

\[
830.0 \text{ (15.0) / (2 \times 404)} = 15.41 \text{ ksi}
\]

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

**Shear**

Actual shear:

\[
F_y = 51.375 \text{ kips}
\]

\[
V_y = D \times t_w = 10.8 \text{ in}^2
\]

\[
f_{v,y} = \frac{F_y}{V_y} = 4.76 \text{ ksi}
\]

Allowable shear:

\( a = \) clear distance between transverse stiffeners (here taken as length) = 80 in
\( h = \) clear distance flanges of the girder = \( D-2t_f = 14.35 \text{ in} \)

Thus, \( a/h = 5.57, \) Therefore, \( k = 5.34 + \left[ \frac{4.00}{(a/h)^2} \right] = 5.46 \)

\[
t = t_w = 0.72 \text{ inch}
\]

\[
C_v = 17.2
\]

\[
F_y = (F_y/2.89)C_v \geq 0.4\times F_y = 14.4 \text{ ksi}
\]

Hence allowable=14.4 ksi

Therefore, Ratio = \( f_v/F_y = 0.330 \)

V. ASME NF 3000 1974 Pipe

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1974 code.

Details

The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force, \( V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \)

Maximum moment, \( M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \)

Slenderness ratio = \( \frac{KL}{r} = 9.72 < 300 \)

Bending About Major Axis (Z-Axis)
Section is compact: \( \frac{OD}{t} = 36.43 < \frac{3 \times 300}{F_y} = 91.67 \)

Allowable bending stress: \( F_b = 0.66 \times F_y = 23.76 \text{ ksi} \)

Actual bending stress: \( f_{btz} = f_{bcz} = \frac{M_z}{T_z} \left( \frac{OD}{2} \right) = \frac{331.25}{262} \left( \frac{12.75}{2} \right) = 8.06 \text{ ksi} \)

Stress ratio: 0.339

Shear

From the reference, the shear area:

\[
A_y = \frac{0.25n(r_2^4 - r_1^4)2(r_2 - r_1)}{2(r_2^3 - r_1^3)}
\]

where

\[
r_1 = \text{inner radius} \\
r_2 = \text{outer radius}
\]

Shear area: \( A_y = 6.8 \text{ in}^2 \)

Actual shear stress (at supports): \( f_v = 25.75 / 6.8 = 3.78 \text{ ksi} \)

Actual shear stress (at midspan): \( f_v = 0.75 / 6.8 = 0.110 \text{ ksi} \)

Allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Stress ratio: 3.78/14.4 = 0.263

</tbody>
</table>
Verify the design of a pipe section used for a beam member per the ASME NF 3000 1974 code.

Details

A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation

Maximum shear force (at support) = \( V = wL + P = (1 \text{ kip/in}) \times 60 \text{ in} + 2 \text{ kip} = 62 \text{ kips} \)

Maximum moment (at support) = \( M = 0.5 \times w \times L^2 + P \times L = 0.5 (1 \text{ kip/in}) \times (60 \text{ in})^2 + (2 \text{ kip}) \times (60 \text{ in}) = 1,920 \text{ in·kips} \)

Slenderness Ratio

Slenderness Ratio along Z-Axis = \( (KL/r)_z = 21.22 \)

Slenderness Ratio along Y-Axis = \( (KL/r)_y = 50.53 \)

Maximum Slenderness Ratio = 50.53 < 300

Bending

Allowable Bending Stress About Major Axis (Z Axis)
\[
b_f/2t_z = 4.65 > 65/\sqrt{(F_Y)} = 10.833
\]
\[
d/w = 28.3 < 640/\sqrt{(F_Y)} = 106.67
\]

Thus allowable bending stress is obtained by treating the section as compact.

\( F_b = 0.66 \times F_Y = 23.8 \text{ ksi} \)

Actual Bending Stress

Bending Tensile Stress = \( f_{btz} = (Mz/Iz) \times Y_{bar} = 14.93 \text{ ksi} < 23.8 \text{ ksi} \)

Bending Compressive Stress = \( f_{bcz} = 38.7 \text{ ksi} > 23.8 \text{ ksi} \)

Critical stress ratio = 38.7 ksi / 23.8 ksi = 1.626

Shear

Allowable Shear Stress

\( a = \text{clear distance between transverse stiffeners (here taken as length)} = 60 \text{ in} \)

\( h = \text{clear distance flanges of the girder} = D-t_f = 17.01 \text{ in} \)
Thus, $a/h = 3.527$ Therefore, $k = 5.34 + \frac{4.00}{(a/h)^2} = 5.65$

$t = t_w = 0.44$ inch

If $Cv > 0.8$, $Cv = \frac{190}{(h/t)} \sqrt{\frac{k}{Sy}} = 78.4$ which is true. Thus, the value of $Cv$ is taken as 78.4

Allowable shear stress $= F_v = (FY/2.89)Cv \leq 0.4F_y = 14.4$ ksi

Hence allowable shear $= 14.4$ ksi

Actual Shear

$V_y = D t_w = 10.68$ in$^2$

$f_v = F_y/V_y = 5.805$ ksi

Stress ratio $= f_v/F_y = 0.403$

---

**V. ASME NF 3000 1974 WShaped**

Verify the design of a wide-flange section used for a cantilever beam using the ASME NF 3000 1974 code.
Details
The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.
The member is a W16X40 section with Grade A36 steel.

Validation
Maximum shear force (constant shear): \( V = 12.5 \text{ kips} \)
Maximum moment (at fixed end): \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1,500 \text{ in \cdot kips} \)

Slenderness Ratio
\( (KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 18.11 \)
\( (KL/r)_y = \text{Slenderness Ratio along Y-Axis} = 76.68 \)
Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

Bending about Major Axis (Z Axis)
Allowable Bending Stress
\[ b_f/2t_f < 6.862 < 65/(F_y)^{0.5} \] [Ref. NF3322.1(d)(2)]
Thus, allowable bending tensile stress = \( f_{btz} = F_y \times [0.79 - 0.002 \times (b_f/2t_f) \times \sqrt{F_y}] = 25.47 \text{ ksi} \)

Actual Bending Stress
Bending Tensile Stress = Bending Compressive Stress = \( f_{btz} = f_{bcz} = M_z D/2I_z = 23.17 \text{ ksi} \)
Stress ratio = 23.16 ksi / 25.47 ksi = 0.909

Shear

Allowable Shear Stress
\( a = \text{clear distance between transverse stiffeners (here taken as length)} = 120 \text{ in} \)
\( h = \text{clear distance flanges of the girder} = D - 2t_f = 14.91 \text{ in} \)
Thus, \( a/h = 8.05 \), Therefore, \( k = 5.34 + [4.00/(a/h)^2] = 5.36 \) [Ref. NF3322.6(e)(2)]
\( t = t_w = 0.3 \text{ inch} \)
\( Cv = 1.475 \)
Allowable shear stress = \( F_v = (F_y/2.89)Cv = > 0.4F_y = 14.4 \text{ ksi} \) Hence allowable=14.4ksi

Actual Shear Stress
\( F_y = 12.5 \text{ kip, Vy} = D t_w = 4.8 \text{ inch}^2 \)
\( f_v = F_y/V_y = 2.6 \text{ ksi} \)
Stress ratio = \( f_v/F_v = 0.18 \)

V. NF 3000-1977

V. ASME NF 3000 1977 Angle

Verify the allowable stress and critical ratio of the brace members in a frame using the ASME NF 3000 1977 code.

Details

The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are "truss" members (axial-only).
Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36 \text{ ksi}, F_u = 58 \text{ ksi}$).
Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

Validation

$$ L = \sqrt{5^2 + 6^2} \times (12 \text{ in/ft}) = 93.726 \text{ in} $$

Slenderness ratio (same for both members) using the minimum value of $r$: $kL/r_z = 0.85(93.726)/1.29 = 61.76$

For member 6, $kL/r_z = 61.76 < 300$
For member 7, $kL/r_z = 61.76 < 200$

**Axial Tension: Member 6 (per NF-77.2211)**

Corrected area, $A_c = C_t \times A_x = 7.57 \text{ in}^2$

Actual tensile stress $= P/A = 2,666.18 \div 7.57 = 352.2 \text{ psi}$

Allowable tensile stress (Tension capacity) $= 0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ ksi}$

Critical ratio $= 352.2/21,600 = 0.016$

**Axial Compression: Member 7 (NF-77.2213):**

Actual compressive stress $= P/A = 7,104.23 \div 8.41 = 844.74 \text{ psi}$

$$ C_c' = \sqrt{\frac{2n^2 E}{Q_e Q_a F_y}} = 126.2 \hspace{1cm} \text{(NF-3322.2(e)(5))} $$

$(kL/r)_{min} < C_c'$, allowable compression stress $F_a = 17.2 \text{ ksi}$

Critical ratio $= 844.74 / 17,200 = 0.049$

ACTUAL STRESSES: (UNIT - POUND)
V. ASME NF 3000 1977 Channel

Verify the design of channel section used for a beam member using the ASME NF 3000 1977 code.

Details

The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.
Validation
Maximum shear force (at fixed end): \( V = 51.375 \text{ kips} \) (taken from STAAD.Pro analysis)
Maximum moment (at fixed end): \( M = 830.0 \text{ in-kip} \) (taken from STAAD.Pro analysis)

Slenderness Ratio
About z-axis: \((KL/r)_z = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95\)
About y-axis: \((KL/r)_y = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61\)
Max. slenderness ratio < 300, OK.

Bending About Major Axis (Z Axis)
\[
\frac{b_f}{t_f} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83
\]
The laterally unsupported length of the compression flange, \( L_b = 80 < \frac{76b_f}{\sqrt{F_y}} = 120\)

As \(b_f/t_f\) is not in the range of \(65/\sqrt{(Fy)}\) and \(95/\sqrt{(Fy)}\), the value of allowable bending compressive and tensile stress = \(F_{by} = F_{bcy} = 0.6\times F_y = 21.6 \text{ ksi}\)

Actual bending stress:
Bending Tensile Stress = bending compressive stress = \(f_{btz} = f_{bcz} = MzD / (2I_z) = 15.4 \text{ ksi}\)

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

Shear
Actual shear:
\[
F_y = 51.375 \text{ kips}
\]
\[
V_y = D\times t_w = 10.8 \text{ in}^2
\]
\[
f_{v,y} = F_y/V_y = 4.76 \text{ksi}
\]
Allowable shear:
an = clear distance between transverse stiffeners (here taken as length) = 80 in
h = clear distance flanges of the girder = \(D-2t_f = 14.35 \text{ in}\)
Thus, \(a/h = 5.57\), Therefore, \(k = 5.34 + [4.00/ (a/h)^2] = 5.46\)
\[
t = t_w = 0.72 \text{ inch}
\]
\[
Cv = 17.2
\]
\[
F_v = (F_y/2.89)C_v \geq 0.4\times F_y = 14.4 \text{ksi}
\]
Hence allowable=14.4 ksi
Therefore, Ratio = \(f_v/F_v = 0.330\)

### ASME NF 3000 1977 Pipe

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1977 code.

**Details**

The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

**Validation**

Maximum shear force, \( V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \)

Maximum moment, \( M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \)

Slenderness ratio = \( \frac{KL}{r} = 9.72 < 300 \)

**Bending About Major Axis (Z-Axis)**
Section is compact: $\frac{OD}{t} = 36.43 < \frac{3}{F_y} = 91.67$

Allowable bending stress: $F_b = 0.66 \times F_y = 23.76$ ksi

Actual bending stress: $f_{btz} = f_{bcz} = \frac{M_z}{I_z} \left(\frac{OD}{2}\right) = \frac{331.25}{262} \left(\frac{12.75}{2}\right) = 8.06$ ksi

Stress ratio: 0.339

Shear

From the reference, the shear area:

$$A_y = \frac{0.25n(r_2^4 - r_1^4)2(r_2 \cdot r_1)}{2(r_2^3 - r_1^3)}$$

where

$r_1$ = inner radius
$r_2$ = outer radius

Shear area: $A_y = 6.8$ in$^2$

Actual shear stress (at supports): $f_v = 25.75 / 6.8 = 3.78$ ksi

Actual shear stress (at midspan): $f_v = 0.75 / 6.8 = 0.110$ ksi

Allowable shear stress, $F_v = 0.4 \times F_y = 14.4$ ksi

Stress ratio: $3.78/14.4 = 0.263$

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1977 code.

Details

A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation

Maximum shear force (at support) = \( V = wL + P = (1 \text{kip/in}) \times 60 \text{in} + 2 \text{kip} = 62 \text{kips} \)

Maximum moment (at support) = \( M = 0.5 \times w \times L^2 + P \times L = 0.5 \times (1 \text{kip/in}) \times (60 \text{in})^2 + (2 \text{kip}) \times (60 \text{in}) = 1,920 \text{in kips} \)

Slenderness Ratio

Slenderness Ratio along Z-Axis = \( (KL/r)_z = 21.22 \)

Slenderness Ratio along Y-Axis = \( (KL/r)_y = 50.53 \)

Maximum Slenderness Ratio = 50.53 < 300

Bending

Allowable Bending Stress About Major Axis (Z Axis)

\[
\frac{b_f^2t_f}{2t_f} = 4.65 > 65/\sqrt{(F_Y)} = 10.833
\]

\[
d/t_w = 28.3 < 640/\sqrt{(F_Y)} = 106.67
\]

Thus allowable bending stress is obtained by treating the section as compact.

\[
F_b = 0.66 \times F_Y = 23.8 \text{ksi}
\]

Actual Bending Stress

Bending Tensile Stress = \( f_{btz} = (Mz/Iz) \times Y_{bar} = 14.93 \text{ksi} < 23.8 \text{ksi} \)

Bending Compressive Stress = \( f_{bcz} = 38.7 \text{ksi} > 23.8 \text{ksi} \)

Critical stress ratio = \( 38.7 \text{ksi} / 23.8 \text{ksi} = 1.626 \)

Shear

Allowable Shear Stress

\[
a = \text{clear distance between transverse stiffeners (here taken as length)} = 60 \text{in}
\]

\[
h = \text{clear distance flanges of the girder} = D - t_f = 17.01 \text{in}
\]
Thus, \( a/h = 3.527 \) Therefore, \( k = 5.34 + \left[ \frac{4.00}{(a/h)^2} \right] = 5.65 \)

\[ t = t_w = 0.44 \text{ inch} \]

If \( Cv > 0.8 \), \( Cv = \left[ \frac{190}{(h/t)} \right] \sqrt{(k/Sy)} = 78.4 \) which is true. Thus, the value of \( Cv \) is taken as 78.4

Allowable shear stress \( = F_v = (FY/2.89)Cv \leq 0.4F_y = 14.4 \text{ ksi} \)

Hence allowable shear \( = 14.4 \text{ ksi} \)

Actual Shear

\[ V_y = D t_w = 10.68 \text{ in}^2 \]

\[ f_v = F_y/V_y = 5.805 \text{ ksi} \]

Stress ratio \( = f_v/F_v = 0.403 \)

**V. ASME NF 3000 1977 WS shaped**

Verify the design of a wide-flange section used for a cantilever beam using the ASME NF 3000 1977 code.
**Details**

The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.

The member is a W16X40 section with Grade A36 steel.

**Validation**

Maximum shear force (constant shear): \( V = 12.5 \text{ kips} \)

Maximum moment (at fixed end): \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1,500 \text{ in} \cdot \text{kips} \)

**Slenderness Ratio**

\( (KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 18.11 \)

\( (KL/r)_y = \text{Slenderness Ratio along Y-Axis} = 76.68 \)

Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

**Bending about Major Axis [Z Axis]**

Allowable Bending Stress

\[ b_f/2t_f = 6.862 < 65/(F_y)^{0.5} \] [Ref. NF3322.1(d)(2)]

Thus, allowable bending tensile stress = \( F_{btz} = F_Y \times (0.79 - 0.002 \times (b_f/2t_f)) \times \sqrt{F_y} = 25.47 \text{ ksi} \)

**Actual Bending Stress**

Bending Tensile Stress = Bending Compressive Stress = \( f_{btz} = f_{bcz} = M_z D / 2I_z = 23.17 \text{ ksi} \)

Stress ratio = 23.16 ksi / 25.47 ksi = 0.909

**Shear**

Allowable Shear Stress

\[ a = \text{clear distance between transverse stiffeners (here taken as length)} = 120 \text{ in} \]

\[ h = \text{clear distance flanges of the girder} = D - 2t_f = 14.91 \text{ in} \]

Thus, \( a/h = 8.05 \), Therefore, \( k = 5.34 + [4.00 / (a/h)^2] = 5.36 \) [Ref. NF3322.6(e)(2)]

\[ t = t_w = 0.3 \text{ inch} \]

\[ Cv = 1.475 \]

Allowable shear stress = \( F_v = (F_y/2.89)Cv = > 0.4F_y = 14.4 \text{ ksi} \) Hence allowable=14.4ksi

**Actual Shear Stress**

\[ F_y = 12.5 \text{ kip, } V_y = D t_w = 4.8 \text{ inch}^2 \]

\[ f_v = F_y/V_y = 2.6 \text{ ksi} \]

Stress ratio = \( f_v/F_v = 0.18 \)

V. NF 3000-1989

V. ASME NF 3000 1989 Angle

Verify the allowable stress and critical ratio of the brace members in a frame using the ASME NF 3000 1989 code.

Details

The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are “truss” members (axial-only).
Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36$ ksi, $F_u = 58$ ksi).

Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

**Validation**

$$L = \sqrt{5^2 + 6^2} (12\text{in/ft}) = 93.726\text{in}$$

Slenderness ratio (same for both members) using the minimum value of $r$: $kL/r = 0.85(93.726)/1.29 = 61.76$

For member 6, $kL/r = 61.76 < 300$

For member 7, $kL/r = 61.76 < 200$

**Axial Tension: Member 6 (per NF-89.1.a)**

Corrected area, $A_c = C_t \times A_x = 7.57 \text{in}^2$

Actual tensile stress = $P/A = 2666.18 / 7.57 = 352.2 \text{psi}$

Allowable tensile stress (Tension capacity) = $0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ksi}$

Critical ratio = $352.2/21,600 = 0.016$

**Axial Compression: Member 7 (NF-89.1.c):**

Actual compressive stress = $P/A = 7,104.23 / 8.41 = 844.74 \text{psi}$

$$C'_C = \sqrt{\frac{2n}{Q_s Q_u F_y}} = 126.2 \text{ (NF-3322.2(e)(5) )}$$

$(kL/r)_{min} < C'_C$, allowable compression stress, $F_a = 17.2 \text{ksi}$

Critical ratio = $844.74 / 17,200 = 0.049$

V. ASME NF 3000 1989 Channel

Verify the design of channel section used for a beam member using the ASME NF 3000 1989 code.

Details

The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.
Validation

Maximum shear force (at fixed end): \( V = 51.375 \text{ kips (taken from STAAD.Pro analysis)} \)

Maximum moment (at fixed end): \( M = 830.0 \text{ in-kip (taken from STAAD.Pro analysis)} \)

Slenderness Ratio

About z-axis: \( (KL/r)_z = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95 \)

About y-axis: \( (KL/r)_y = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61 \)

Max. slenderness ratio < 300, OK.

Bending About Major Axis (Z Axis)

\[
\frac{b_f}{t_f} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83
\]

The laterally unsupported length of the compression flange, \( L_b = 80 < \frac{76b_f}{\sqrt{F_y}} = 120 \)

and \( < \frac{20,000}{(d/A_f)F_y} = 89.56 \)

As \( b_f/t_f \) is not in the range of \( 65/\sqrt{(F_y)} \) and \( 95/\sqrt{(F_y)} \), the value of allowable bending compressive and tensile stress \( F_{by} = F_{bcy} = 0.6 \times F_y = 21.6 \text{ ksi} \)

Actual bending stress:

Bending Tensile Stress = bending compressive stress = \( f_{btz} = f_{bcz} = MzD / (2I_z) = 15.4 \text{ ksi} \)

830.0 \( (15.0) / (2 \times 404) = 15.41 \text{ ksi} \)

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

Shear

Actual shear:

\( F_y = 51.375 \text{ kips} \)

\( V_y = D \times t_w = 10.8 \text{ in}^2 \)

\( f_{v,y} = F_y/V_y = 4.76 \text{ ksi} \)

Allowable shear:

\( a = \text{clear distance between transverse stiffeners (here taken as length)} = 80 \text{ in} \)

\( h = \text{clear distance flanges of the girder} = D-2t_f = 14.35 \text{ in} \)

Thus, \( a/h = 5.57, \) Therefore, \( k = 5.34 + [4.00/ (a/h)^2] = 5.46 \)

\( t = t_w = 0.72 \text{ inch} \)

\( C_v = 17.2 \)

\( F_y = (F_y/2.89)C_v \geq 0.4 \times F_y = 14.4 \text{ ksi} \)

Hence allowable=14.4 ksi

Therefore, Ratio = \( f_v/F_v = 0.330 \)

V. ASME NF 3000 1989 Pipe

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1989 code.

Details

The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force, \[ V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \]

Maximum moment, \[ M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)^2}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \]

Slenderness ratio = \( \frac{KL}{r} \) = 9.72 < 300

Bending About Major Axis (Z-Axis)
Section is compact: \[ \frac{OD}{t} = 36.43 < \frac{3.300}{F_y} = 91.67 \]

Allowable bending stress: \[ F_b = 0.66 \times F_y = 23.76 \text{ ksi} \]

Actual bending stress: \[ f_{btz} = f_{bcz} = \frac{M_z}{I_z} \left( \frac{OD}{2} \right) = \frac{331.25}{262} \left( \frac{12.75}{2} \right) = 8.06 \text{ ksi} \]

Stress ratio: 0.339

**Shear**

From the reference, the shear area:

\[ A_y = \frac{0.25n(r_2^4 - r_1^4)2(r_2 \cdot r_1)}{2(r_2^3 - r_1^3)} \]

where

- \( r_1 = \) inner radius
- \( r_2 = \) outer radius

Shear area: \( A_y = 6.8 \text{ in}^2 \)

Actual shear stress (at supports): \( f_v = 25.75 / 6.8 = 3.78 \text{ ksi} \)

Actual shear stress (at midspan): \( f_v = 0.75 / 6.8 = 0.110 \text{ ksi} \)

Allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Stress ratio: \( 3.78/14.4 = 0.263 \)

**Results**

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1989 code.

Details

A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation

Maximum shear force (at support) \( V = wL + P = (1 \text{ kip/in}) \times 60 \text{ in} + 2 \text{ kip} = 62 \text{ kips} \)

Maximum moment (at support) \( M = 0.5 \times w \times L^2 + P \times L = 0.5 (1 \text{ kip/in}) \times (60 \text{ in})^2 + (2 \text{ kip}) \times (60 \text{ in}) = 1,920 \text{ in.kips} \)

Slenderness Ratio

Slenderness Ratio along Z-Axis \( (KL/r)_z = 21.22 \)

Slenderness Ratio along Y-Axis \( (KL/r)_y = 50.53 \)

Maximum Slenderness Ratio \( = 50.53 < 300 \)

Bending

Allowable Bending Stress About Major Axis (Z Axis)
\[
\frac{b}{2t_f} = 4.65 > 65/\sqrt{F_Y} = 10.833
\]
\[
d/w = 28.3 < 640/\sqrt{F_Y} = 106.67
\]

Thus allowable bending stress is obtained by treating the section as compact.

\( F_b = 0.66 \times F_Y = 23.8 \text{ ksi} \)

Actual Bending Stress

Bending Tensile Stress \( f_{btz} = (Mz/Iz) \times Y_{bar} = 14.93 \text{ ksi} < 23.8 \text{ ksi} \)

Bending Compressive Stress \( f_{bcz} = 38.7 \text{ ksi} > 23.8 \text{ ksi} \)

Critical stress ratio \( = 38.7 \text{ ksi} / 23.8 \text{ ksi} = 1.626 \)

Shear

Allowable Shear Stress
\[
a = \text{ clear distance between transverse stiffeners (here taken as length)} = 60 \text{ in}
\]
\[
h = \text{ clear distance flanges of the girder} = D-t_f = 17.01 \text{ in}
\]
Thus, $a/h = 3.527$ Therefore, $k = 5.34 + \frac{4.00}{(a/h)^2} = 5.65$

$t = t_w = 0.44$ inch

If $Cv > 0.8$, $Cv = \frac{190}{(h/t)} \sqrt{(k/Sy)} = 78.4$ which is true. Thus, the value of $Cv$ is taken as 78.4.

Allowable shear stress $= F_v = (FY/2.89)Cv \leq 0.4FY = 14.4$ ksi

Hence allowable shear $= 14.4$ ksi.

Actual Shear

$V_y = Dt_w = 10.68$ in$^2$

$f_v = F_y/V_y = 5.805$ ksi

Stress ratio $= f_v/F_v = 0.403$

Verification Examples

V. ASME NF 3000 1989 WShaped

Verify the design of a wide-flange section used for a cantilever beam using the ASME NF 3000 1989 code.
Details
The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.
The member is a W16X40 section with Grade A36 steel.
Validation
Maximum shear force (constant shear): \( V = 12.5 \text{ kips} \)
Maximum moment (at fixed end): \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1,500 \text{ in} \cdot \text{kips} \)
Slenderness Ratio
\( (KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 18.11 \)
\( (KL/r)_y = \text{Slenderness Ratio along Y-Axis} = 76.68 \)
Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)
Bending about Major Axis [Z Axis]
Allowable Bending Stress
\[ \frac{b_f/2t_f}{2} < 65/(F_y)^{0.5} \text{ [Ref. NF3322.1(d)(2)]} \]
Thus, allowable bending tensile stress = \( F_{btz} = F_y \times [0.79-0.002 \times (b_f/2t_f) \times \sqrt{F_y}] = 25.47 \text{ ksi} \)
Actual Bending Stress
\[ \text{Bending Tensile Stress} = \text{Bending Compressive Stress} = f_{btz} = f_{bcz} = M_z D / 2I_z = 23.17 \text{ ksi} \]
Stress ratio = 23.16 ksi / 25.47 ksi = 0.909
Shear
\[ a = \text{clear distance between transverse stiffeners (here taken as length)} = 120 \text{ in} \]
\[ h = \text{clear distance flanges of the girder} = D - 2t_f = 14.91 \text{ in} \]
Thus, \( a/h = 8.05 \), Therefore, \( k = 5.34 + [4.00 / (a/h)^2] = 5.36 \text{ [Ref. NF3322.6(e)(2)]} \)
\[ t = t_w = 0.3 \text{ inch} \]
\[ C_v = 1.475 \]
Allowable shear stress = \( F_v = (F_y/2.89)C_v = > 0.4F_y = 14.4 \text{ ksi} \) Hence allowable=14.4ksi
Actual Shear Stress
\[ F_y = 12.5 \text{ kip}, \ V_y = D t_w = 4.8 \text{ inch}^2 \]
\[ f_v = F_y/V_y = 2.6 \text{ ksi} \]
Stress ratio = \( f_v/F_v = 0.18 \)

V. NF 3000-1998

V. ASME NF 3000 1998 Angle

Verify the allowable stress and critical ratio of the brace members in a frame using the ASME NF 3000 1998 code.

Details

The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are “truss” members (axial-only).
Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36 \text{ ksi}$, $F_{u} = 58 \text{ ksi}$).
Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

Validation

$$L = \sqrt{5^2 + 6^2} \ (12\text{in/ft}) = 93.726\text{in}$$

Slenderness ratio (same for both members) using the minimum value of $r$: $kL/r_z = 0.85(93.726)/1.29 = 61.76$

For member 6, $kL/r_z = 61.76 < 300$
For member 7, $kL/r_z = 61.76 < 200$

Axial Tension: Member 6 (per NF-98.1.a)
Corrected area, $A_c = C_t \times A_x = 7.57 \text{ in}^2$
Actual tensile stress $= P/A = 2,666.18 / 7.57 = 352.2 \text{ psi}$
Allowable tensile stress (Tension capacity) $= 0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ ksi}$
Critical ratio $= 352.2/21,600 = 0.016$

Axial Compression: Member 7 (NF-98.1.c):  
Actual compressive stress $= P/A = 7,104.23 / 8.41 = 844.74 \text{ psi}$

$$C_c' = \sqrt{\frac{2n^2E}{Q_x Q_y F_y}} = 126.2 \quad \text{(NF-3322.2(e)(5))}$$

$(kL/r)_{min} < C_c'$, allowable compression stress, $F_{a} = 17.2 \text{ ksi}$
Critical ratio $= 844.74 / 17,200 = 0.049$

**V. ASME NF 3000 1998 Channel**

Verify the design of channel section used for a beam member using the ASME NF 3000 1998 code.

**Details**

The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.
Validation
Maximum shear force (at fixed end): $V = 51.375 \text{ kips}$ (taken from STAAD.Pro analysis)
Maximum moment (at fixed end): $M = 830.0 \text{ in-kip}$ (taken from STAAD.Pro analysis)

Slenderness Ratio
About z-axis: $(KL/r)_z = 0.85\text{(80 in)}/(5.25 \text{ in}) = 12.95$
About y-axis: $(KL/r)_y = 0.85\text{(80 in)}/(0.865 \text{ in}) = 78.61$
Max. slenderness ratio < 300, OK.

Bending About Major Axis (Z Axis)

$$\frac{b_f}{t_f} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83$$

The laterally unsupported length of the compression flange, $L_b = 80 < \frac{76b_f}{\sqrt{F_y}} = 120$

and $< \frac{20,000}{(d/ A_f)F_y} = 89.56$

As $b_f/t_f$ is not in the range of $65/\sqrt{F_y}$ and $95/\sqrt{F_y}$, the value of allowable bending compressive and tensile stress $= F_{by} = F_{cy} = 0.6 \times F_y = 21.6 \text{ ksi}$

Actual bending stress:

Bending Tensile Stress = bending compressive stress $= f_{btz} = f_{bcz} = MzD / (2I_z) = 15.4 \text{ ksi}$

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

Shear
Actual shear:

$F_y = 51.375 \text{ kips}$
$V_y = D \times t_w = 10.8 \text{ in}^2$
$f_{v,y} = F_y/V_y = 4.76 \text{ ksi}$

Allowable shear:

a = clear distance between transverse stiffeners (here taken as length) = 80 in
h = clear distance flanges of the girder = $D-2t_f = 14.35 \text{ in}$

Thus, $a/h = 5.57$, Therefore, $k = 5.34 + [4.00/ (a/h)^2] = 5.46$

$t = t_w = 0.72 \text{ inch}$

$C_v = 17.2$

$F_v = (F_y/2.89)C_v \geq 0.4 \times F_y = 14.4 \text{ ksi}$

Hence allowable=14.4 ksi

Therefore, Ratio $= f_v/F_v = 0.330$

V. ASME NF 3000 1998 Pipe

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1998 code.

Details

The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force,
\[ V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \]

Maximum moment,
\[ M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \]

Slenderness ratio = \( \frac{KL}{r} \) = 9.72 < 300

Bending About Major Axis (Z-Axis)

Section is compact: \( \frac{OD}{r} = 36.43 < 3 \times \frac{300}{F_y} = 91.67 \)

Allowable bending stress: \( F_b = 0.66 \times F_y = 23.76 \text{ ksi} \)

Actual bending stress:
\[ f_{bz} = f_{bcz} = \frac{M_z}{I_z} \left( \frac{OD}{2} \right) = \frac{331.25 \left( \frac{12.75}{2} \right)}{262} = 8.06 \text{ksi} \]

Stress ratio: 0.339

Shear

From the reference, the shear area:
\[ A_y = \frac{0.25 \left( r_2^4 - r_1^4 \right) \left( r_2 - r_1 \right)}{2 \left( r_2^3 - r_1^3 \right)} \]

where
\[ r_1 = \text{inner radius} \]
\[ r_2 = \text{outer radius} \]

Shear area: \( A_y = 6.8 \text{ in}^2 \)

Actual shear stress (at supports): \( f_v = 25.75 / 6.8 = 3.78 \text{ ksi} \)

Actual shear stress (at midspan): \( f_v = 0.75 / 6.8 = 0.110 \text{ ksi} \)

Allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Stress ratio: 3.78/14.4 = 0.263

**Verification Examples**

**V.09 Steel Design**

```plaintext
STAAD.Pro
4194
User Manual
```
V. ASME NF 3000 1998 Tee

Verify the design of a pipe section used for a beam member per the ASME NF 3000 1998 code.

Details

A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation

Maximum shear force (at support) \( V = wL + P = (1 \text{ kip/in}) \times 60 \text{ in} + 2 \text{ kip} = 62 \text{ kips} \)

Maximum moment (at support) \( M = 0.5 \times w \times L^2 + P \times L = 0.5 (1 \text{ kip/in}) \times (60 \text{ in})^2 + (2 \text{ kip}) \times (60 \text{ in}) = 1,920 \text{ in-kips} \)

Slenderness Ratio

Slenderness Ratio along Z-Axis \( (KL/r)_z = 21.22 \)

Slenderness Ratio along Y-Axis \( (KL/r)_y = 50.53 \)
Maximum Slenderness Ratio = 50.53 < 300

**Bending**

**Allowable Bending Stress About Major Axis (Z Axis)**
\[
\frac{bf}{2t_f} = 4.65 > 65/\sqrt{(F_Y)} = 10.833
\]
\[
d/t_w = 28.3 < 640/\sqrt{(F_Y)} = 106.67
\]
Thus allowable bending stress is obtained by treating the section as compact.

\[
F_b = 0.66 \times F_Y = 23.8 \text{ ksi}
\]

**Actual Bending Stress**

Bending Tensile Stress \( f_{btz} = (Mz/Iz) \times Y_{bar} = 14.93 \text{ ksi} < 23.8 \text{ ksi} \)

Bending Compressive Stress \( f_{bcz} = 38.7 \text{ ksi} > 23.8 \text{ ksi} \)

Critical stress ratio \( 38.7 \text{ ksi} / 23.8 \text{ ksi} = 1.626 \)

**Shear**

**Allowable Shear Stress**

a = clear distance between transverse stiffeners (here taken as length) = 60 in

h = clear distance flanges of the girder = \( D-t_f = 17.01 \text{ in} \)

Thus, \( a/h = 3.527 \) Therefore, \( k = 5.34 + \left[ \frac{4.00}{(a/h)^2} \right] = 5.65 \)

\[ t = t_w = 0.44 \text{ inch} \]

If \( Cv > 0.8 \), \( Cv = \left[ \frac{190}{(h/t)} \right] \sqrt{(h/S_y)} = 78.4 \) which is true. Thus, the value of \( Cv \) is taken as 78.4

Hence allowable shear = 14.4 ksi

**Actual Shear**

\[ V_y = D t_w = 10.68 \text{ in}^2 \]

\[ f_v = F_Y/V_y = 5.805 \text{ ksi} \]

Stress ratio = \( f_v/F_v = 0.403 \)

**Results**

```
V. ASME NF 3000 1998 WShaped

Verify the design of a wide-flange section used for a cantilever beam using the ASME NF 3000 1998 code.

Details

The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.

The member is a W16X40 section with Grade A36 steel.

Validation

Maximum shear force (constant shear): \( V = 12.5 \text{ kips} \)

Maximum moment (at fixed end): \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1,500 \text{ in kips} \)

Slenderness Ratio

\((KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 18.11\)

\((KL/r)_y = \text{Slenderness Ratio along Y-Axis} = 76.68\)

Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

Bending about Major Axis (Z Axis)

Allowable Bending Stress

\( f_{btz} = \frac{F_y}{0.79 - 0.002\left(b/t_f\right)\sqrt{F_y}} = 25.47 \text{ ksi} \)

Actual Bending Stress

\( f_{tz} = f_{tcz} = \frac{M/I_z}{2I_z} = 23.17 \text{ ksi} \)

Stress ratio = \( 23.16 \text{ ksi} / 25.47 \text{ ksi} = 0.909 \)

Shear
Allowable Shear Stress

a = clear distance between transverse stiffeners (here taken as length) = 120 in

h = clear distance flanges of the girder = D-2t_f = 14.91 in

Thus, a/h = 8.05, Therefore, k = 5.34 + [4.00/ (a/h)^2] = 5.36 [Ref. NF3322.6(e)(2)]

t = t_w = 0.3 inch

Cv = 1.475

Allowable shear stress = F_v = (F_y/2.89)Cv = > 0.4F_y = 14.4 ksi Hence allowable=14.4 ksi

Actual Shear Stress

F_y = 12.5 kip, V_y = D_t_w = 4.8 inch^2

f_v = F_y/V_y = 2.6 ksi

Stress ratio = f_v/F_v = 0.18

V. NF 3000-2001

V. ASME NF 3000 2001 Angle

Verify the allowable stress and critical ratio of the brace members in a frame using the ASME NF 3000 2001 code.
The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are “truss” members (axial-only).

Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36 \text{ ksi}, F_u = 58 \text{ ksi}$). Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

**Validation**

$L = \sqrt{5^2 + 6^2}(12\text{in/ft}) = 93.726\text{in}$

Slenderness ratio (same for both members) using the minimum value of $r$: $kL/r_z = 0.85(93.726)/1.29 = 61.76$

For member 6, $kL/r_z = 61.76 < 300$

For member 7, $kL/r_z = 61.76 < 200$

**Axial Tension: Member 6**

Corrected area, $A_c = C_t \times A_x = 7.57 \text{in}^2$

Actual tensile stress $= P/A = 2,666.18 \div 7.57 = 352.2 \text{ psi}$

Allowable tensile stress (Tension capacity) $= 0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ksi}$

Critical ratio $= 352.2/21,600 = 0.016$

**Axial Compression: Member 7**

Actual compressive stress $= P/A = 7,104.23 \div 8.41 = 844.74 \text{ psi}$

$C_c' = \frac{2n^2E}{Q_u Q_d F_y} = 126.2$ \hspace{1cm} (NF-3322.2(e)(5))

$(kL/r)_{\text{min}} < C_c'$, allowable compression stress, $F_a = 17.2 \text{ksi}$
Critical ratio = \( \frac{844.74}{17,200} = 0.049 \)

V. ASME NF 3000 2001 Channel

Verify the design of channel section used for a beam member using the ASME NF 3000 2001 code.

Details
The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.

Validation

Maximum shear force (at fixed end): \( V = 51.375 \text{ kips} \) (taken from STAAD.Pro analysis)

Maximum moment (at fixed end): \( M = 830.0 \text{ in-kip} \) (taken from STAAD.Pro analysis)

Slenderness Ratio

About z-axis: \( (KL/r)_{z} = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95 \)

About y-axis: \( (KL/r)_{y} = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61 \)

Max. slenderness ratio < 300, OK.

Bending About Major Axis (Z Axis)

\[
\frac{b_{f}}{t_{f}} = 4.62 < \frac{65}{\sqrt{F_{y}}} = 10.83
\]

The laterally unsupported length of the compression flange, \( L_{b} = 80 \text{ in} < \frac{76b_{f}}{\sqrt{F_{y}}} = 120 \)

and \( < \frac{20,000}{(d/A_{f})F_{y}} = 89.56 \)

As \( b_{f}/t_{f} \) is not in the range of \( 65/\sqrt{(F_{y})} \) and \( 95/\sqrt{(F_{y})} \), the value of allowable bending compressive and tensile stress = \( F_{bty} = F_{bcy} = 0.6\times F_{y} = 21.6 \text{ ksi} \)

Actual bending stress:

Bending Tensile Stress = bending compressive stress = \( f_{btz} = f_{bcz} = \frac{MzD}{(2I_{z})} = 15.4 \text{ ksi} \)

\[
830.0 \times (15.0) / (2 \times 404) = 15.41 \text{ ksi}
\]

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

Shear

Actual shear:

\[
F_{y} = 51.375 \text{ kips}
\]

\[
V_{y} = D\times t_{w} = 10.8 \text{ in}^{2}
\]

\[
f_{v,y} = F_{y}/V_{y} = 4.76 \text{ ksi}
\]

Allowable shear:

\[ a = \text{clear distance between transverse stiffeners (here taken as length)} = 80 \text{ in} \]

\[ h = \text{clear distance flanges of the girder} = D-2t_{f} = 14.35 \text{ in} \]

Thus, \( a/h = 5.57 \), Therefore, \( k = 5.34 + [4.00/ (a/h)^{2}] = 5.46 \)

\[
t = t_{w} = 0.72 \text{ inch}
\]

\[
Cv = 17.2
\]

\[
F_{v} = (F_{y}/2.89)C_{v} \geq 0.4\times F_{y} = 14.4 \text{ ksi}
\]

Hence allowable = 14.4 ksi
Therefore, \( \text{Ratio} = \frac{f_v}{F_v} = 0.330 \)

Verify the design of a pipe section used for a beam member per the ASME NF 3000 2001 code.

Details
The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force,
\[ V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \]

Maximum moment,
\[ M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \]

Slenderness ratio = \( KL/r \) = 9.72 < 300

Bending About Major Axis (Z-Axis)

Section is compact: \( \frac{OD}{r} = 36.43 < 3 \frac{300}{F_y} = 91.67 \)

Allowable bending stress: \( F_b = 0.66 \times F_y = 23.76 \text{ksi} \)

Actual bending stress:
\[ f_{btz} = f_{bcz} = \frac{M_z}{I_z} \left( \frac{OD}{2} \right)^2 = \frac{331.25}{262} \left( \frac{12.75}{2} \right) = 8.06 \text{ksi} \]

Stress ratio: 0.339

Shear

From the reference, the shear area:
\[ A_y = \frac{0.25n(r_2^4 - r_1^4)}{2(r_2^3 - r_1^3)} \]

where
\[ r_1 = \text{inner radius} \]
\[ r_2 = \text{outer radius} \]

Shear area: \( A_y = 6.8 \text{ in}^2 \)

Actual shear stress (at supports): \( f_v = 25.75 / 6.8 = 3.78 \text{ ksi} \)

Actual shear stress (at midspan): \( f_v = 0.75 / 6.8 = 0.110 \text{ ksi} \)
Allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Stress ratio: \( \frac{3.78}{14.4} = 0.263 \)

Verification Examples
V.09 Steel Design

STAAD.Pro 4214 User Manual
V. ASME NF 3000 2001 Tee

Verify the design of a pipe section used for a beam member per the ASME NF 3000 2001 code.

Details

A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation
Maximum shear force (at support) = \( V = wL + P = (1 \text{ kip/in}) \times 60 \text{ in} + 2 \text{ kip} = 62 \text{ kips} \)

Maximum moment (at support) = \( M = 0.5 \times w \times L^2 + P \times L = 0.5 (1 \text{ kip/in}) \times (60 \text{ in})^2 + (2 \text{ kip}) \times (60 \text{ in}) = 1,920 \text{ in kips} \)

Slenderness Ratio

Slenderness Ratio along Z-Axis = \( (KL/r)_z = 21.22 \)

Slenderness Ratio along Y-Axis = \( (KL/r)_y = 50.53 \)

Maximum Slenderness Ratio = 50.53 < 300

Bending

Allowable Bending Stress About Major Axis (Z Axis)

\[
\frac{b f}{2 t f} = 4.65 > \frac{65}{\sqrt{F_Y}} = 10.833
\]

\[
d/t_w = 28.3 < \frac{640}{\sqrt{F_Y}} = 106.67
\]

Thus allowable bending stress is obtained by treating the section as compact.

\[
F_b = 0.66 \times F_Y = 23.8 \text{ ksi}
\]

Actual Bending Stress

Bending Tensile Stress = \( f_{btz} = (Mz/Iz) \times Y_{bar} = 14.93 \text{ ksi} < 23.8 \text{ ksi} \)

Bending Compressive Stress = \( f_{bcz} = 38.7 \text{ ksi} > 23.8 \text{ ksi} \)

Critical stress ratio = \( 38.7 \text{ ksi} / 23.8 \text{ ksi} = 1.626 \)

Shear

Allowable Shear Stress

\[
a = \text{clear distance between transverse stiffeners (here taken as length)} = 60 \text{ in}
\]

\[
h = \text{clear distance flanges of the girder} = D-t_f = 17.01 \text{ in}
\]

Thus, \( a/h = 3.527 \) Therefore, \( k = 5.34 + [4.00/ (a/h)^2] = 5.65 \)

\[
t = t_w = 0.44 \text{ inch}
\]

If \( Cv > 0.8, \ Cv = [190/(h/t)]\sqrt{(k/Sy)} = 78.4 \) which is true. Thus, the value of \( Cv \) is taken as 78.4

Allowable shear stress = \( F_V = (F_Y/2.89)Cv \leq 0.4F_Y = 14.4 \text{ ksi} \)

Hence allowable shear = 14.4ksi

Actual Shear

\[
V_y = Dt_w = 10.68 \text{ in}^2
\]

\[
f_v = F_Y/V_y = 5.805 \text{ ksi}
\]

Stress ratio = \( f_v/F_V = 0.403 \)

STAAD.Pro 4218 User Manual
V. ASME NF 3000 2001 WShaped

Verify the design of a wide-flange section used for a cantilever beam using the ASME NF 3000 2001 code.

Details

The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.

The member is a W16X40 section with Grade A36 steel.

Validation

Maximum shear force (constant shear): $V = 12.5 \text{kips}$

Maximum moment (at fixed end): $M = 12.5 \text{kips} \times 120 \text{ in} = 1,500 \text{ in kips}$

Slenderness Ratio

$$(K_{L/r})_z = \text{Slenderness Ratio along Z-Axis} = 18.11$$

$$(K_{L/r})_y = \text{Slenderness Ratio along Y-Axis} = 76.68$$

Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

Bending about Major Axis (Z Axis)

Allowable Bending Stress

$$\frac{b_f}{2t} = 6.862 < 65/(F_y)^{0.5} \text{ [Ref. NF3322.1(d)(2)]}$$
Thus, allowable bending tensile stress \( F_{btz} = F_y \times \{0.79 - 0.002 \times (b_f/2t_f) \times \sqrt{F_y} \} = 25.47 \text{ksi} \)

Actual Bending Stress

Bending Tensile Stress = Bending Compressive Stress \( f_{btz} = f_{bcz} = M_z/D/2I_z = 23.17 \text{ksi} \)

Stress ratio = \( 23.16 \text{ksi} / 25.47 \text{ksi} = 0.909 \)

Shear

Allowable Shear Stress

\( a = \) clear distance between transverse stiffeners (here taken as length) = 120 in

\( h = \) clear distance flanges of the girder = \( D-2t_f = 14.91 \text{in} \)

Thus, \( a/h = 8.05 \), Therefore, \( k = 5.34 + \{4.00/ (a/h)^2\} = 5.36 \) [Ref. NF3322.6(e)(2)]

\[ t = t_w = 0.3 \text{inch} \]

\[ Cv = 1.475 \]

Allowable shear stress \( F_v = (F_y/2.89)Cv = > 0.4F_y = 14.4 \text{ksi} \) Hence allowable = 14.4 ksi

Actual Shear Stress

\( F_y = 12.5 \text{kip}, \ V_y = D t_w = 4.8 \text{inch}^2 \)

\( f_v = F_y/V_y = 2.6 \text{ksi} \)

Stress ratio = \( f_v/F_v = 0.18 \)

**STAAD.Pro 4222 User Manual**
**V. NF 3000-2004**

**V. ASME NF 3000 2004 Angle**

Verify the allowable stress and critical ratio of the brace members in a frame using the ASME NF 3000 2004 code.

Details

The forces due to loading in member 6 is 2,666.18 lbs (tension) and in member 7 is 7,104.23 lbs (compression). Members 6 and 7 are “truss” members (axial-only).

![Figure 453: Space frame subjected to static loads](image)

Both member 6 and 7 are L 80x60x10, grade A36 steel ($F_y = 36$ ksi, $F_u = 58$ ksi).

Assume a net section factor of 0.9, an effective length factor of 0.85, and $C_t = 0.9$.

Validation

\[
L = \sqrt{5^2 + 6^2} \text{(12in/ft)} = 93.726\text{in}
\]

Slenderness ratio (same for both members) using the minimum value of \(r\): $kL/r_z = 0.85(93.726)/1.29 = 61.76$

For member 6, \(kL/r_z = 61.76 < 300\)

For member 7, \(kL/r_z = 61.76 < 200\)

Axial Tension: Member 6

Corrected area, $A_c = C_t \times A_x = 7.57 \text{ in}^2$
Actual tensile stress = \( P/A = 2,666.18 / 7.57 = 352.2 \text{ psi} \)

Allowable tensile stress (Tension capacity) = \( 0.6 \times F_y = 0.6 \times 36 = 21.6 \text{ ksi} \)

Critical ratio = \( 352.2 / 21,600 = 0.016 \)

**Axial Compression: Member 7**

Actual compressive stress = \( P/A = 7,104.23 / 8.41 = 844.74 \text{ psi} \)

\[
C'_c = \sqrt{\frac{2\pi^2E}{\alpha_s \alpha_a F_y}} = 126.2
\]  

\((kL/r)_{\text{min}} < C'_c\), allowable compression stress, \( F_a = 17.2 \text{ ksi} \)

Critical ratio = \( 844.74 / 17,200 = 0.049 \)

Results

**V. ASME NF 3000 2004 Channel**

Verify the design of channel section used for a beam member using the ASME NF 3000 2004 code.

**Details**

The beam is a propped cantilever 80 inches long. The beam is loaded with a 2 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is C15x50 channel section with Grade A36 steel.

**Validation**

Maximum shear force (at fixed end): \( V = 51.375 \text{ kips} \) (taken from STAAD.Pro analysis)

Maximum moment (at fixed end): \( M = 830.0 \text{ in-kip} \) (taken from STAAD.Pro analysis)

**Slenderness Ratio**

About z-axis: \( (KL/r)_z = 0.85(80 \text{ in})/(5.25 \text{ in}) = 12.95 \)

About y-axis: \( (KL/r)_y = 0.85(80 \text{ in})/(0.865 \text{ in}) = 78.61 \)

Max. slenderness ratio < 300, OK.

**Bending About Major Axis (Z Axis)**

\[
\frac{b_f}{t_f} = 4.62 < \frac{65}{\sqrt{F_y}} = 10.83
\]

The laterally unsupported length of the compression flange, \( L_b = 80 < \frac{76b_f}{\sqrt{F_y}} = 120 \)

and \( < \frac{20,000}{(d/A_f)F_y} = 89.56 \)

As \( b_f/t_f \) is not in the range of \( 65/\sqrt{(F_y)} \) and \( 95/\sqrt{(F_y)} \), the value of allowable bending compressive and tensile stress = \( F_{bty} = F_{bcy} = 0.6 \times F_y = 21.6 \text{ ksi} \)

Actual bending stress:

Bending Tensile Stress = bending compressive stress = \( f_{btz} = f_{bcz} = \frac{MzD}{(2I_z)} = 15.4 \text{ ksi} \)

\[
830.0 \text{ (15.0) } / (2 \times 404) = 15.41 \text{ ksi}
\]

Critical ratio = 15.41 ksi / 21.6 ksi = 0.713

**Shear**

Actual shear:

\[
F_y = 51.375 \text{ kips} \\
V_y = D \times t_w = 10.8 \text{ in}^2 \\
f_{v,y} = F_y/V_y = 4.76 \text{ ksi}
\]

Allowable shear:
a = clear distance between transverse stiffeners (here taken as length) = 80 in
h = clear distance flanges of the girder = D-2t = 14.35 in
Thus, a/h = 5.57, Therefore, k = 5.34 + [4.00/ (a/h)²] = 5.46

\[ t = t_w = 0.72 \text{ inch} \]

\[ C_v = 17.2 \]

\[ F_v = (F_y/2.89)C_v \geq 0.4 \times F_y = 14.4 \text{ ksi} \]

Hence allowable=14.4 ksi
Therefore, Ratio = \( f_v/F_v = 0.330 \)

SLENDERNESS CHECK: ACTUAL RATIO: 78.61 ALLOWABLE RATIO: 300.00
ALLOWABLE STRESSES: (UNIT - POUN INCH)
AXIAL: 1.55E+04  FCZ: 2.16E+04  FCY: 2.16E+04  FTZ: 2.16E+04  FTY: 2.16E
V. ASME NF 3000 2004 Pipe

Verify the design of a pipe section used for a beam member per the ASME NF 3000 2004 code.

Details
The simply supported beam is 50 inches long. The beam is loaded with a 1.5 kip concentrated load at midspan and a uniformly distributed load of 1 kip/in over the entire length.

The member is PIPS 120 pipe section with Grade A36 steel.

Validation

Maximum shear force, \( V = \frac{P}{2} + \frac{wL}{2} = \frac{1.5}{2} + \frac{1.0(50)}{2} = 25.75 \text{kips} \)

Maximum moment, \( M = \frac{PL}{4} + \frac{wL^2}{8} = \frac{1.5(50)}{4} + \frac{1.0(50)^2}{8} = 331.25 \text{in} \cdot \text{kip} \)

Slenderness ratio = \( (KL/r) = 9.72 < 300 \)

Bending About Major Axis (Z-Axis)

Section is compact: \( \frac{OD}{t} = 36.43 \times \frac{300}{F_y} = 91.67 \)

Allowable bending stress: \( F_b = 0.66 \times F_y = 23.76 \text{ksi} \)

Actual bending stress: \( f_{btz} = f_{bcz} = \frac{Mz}{Iz} \left( \frac{OD}{2} \right) = \frac{331.25 \left( \frac{12.75}{2} \right)}{262} = 8.06 \text{ksi} \)

Stress ratio: 0.339

Shear

From the reference, the shear area:

\[
A_y = \frac{0.25\pi r_2^4 - r_1^4}{2\pi (r_2^3 - r_1^3)}
\]

where

\( r_1 = \text{inner radius} \)
\( r_2 = \text{outer radius} \)

Shear area: \( A_y = 6.8 \text{ in}^2 \)

Actual shear stress (at supports): \( f_v = 25.75 / 6.8 = 3.78 \text{ ksi} \)

Actual shear stress (at midspan): \( f_v = 0.75 / 6.8 = 0.110 \text{ ksi} \)

Allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Stress ratio: 3.78/14.4 = 0.263

V. ASME NF 3000 2004 Tee

Verify the design of a pipe section used for a beam member per the ASME NF 3000 2004 code.

Details

A cantilever beam is 60 in long. The beam is loaded at the free end with a 2 kip load and a uniform load of 1 kip/in along the entire length.

The member is a WT18x67.5 section with Grade A36 steel.

Validation

Maximum shear force (at support) = \( V = wL + P = (1 \text{ kip/in}) \times 60 \text{ in} + 2 \text{ kip} = 62 \text{ kips} \)

Maximum moment (at support) = \( M = 0.5 \times w \times L^2 + P \times L = 0.5 (1 \text{ kip/in}) \times (60 \text{ in})^2 + (2 \text{ kip}) \times (60 \text{ in}) = 1,920 \text{ in\ kips} \)

Slenderness Ratio

Slenderness Ratio along Z-Axis = \((KL/r)_z = 21.22\)

Slenderness Ratio along Y-Axis = \((KL/r)_y = 50.53\)

Maximum Slenderness Ratio = 50.53 < 300

Bending

Allowable Bending Stress About Major Axis (Z Axis)

\[ \frac{b'_f}{2t_f} = 4.65 > 65/\sqrt{(F_Y)} = 10.833 \]
\[ \frac{d}{t_w} = 28.3 < \frac{640}{\sqrt{F_Y}} = 106.67 \]

Thus allowable bending stress is obtained by treating the section as compact.

\[ F_b = 0.66 \times F_Y = 23.8 \text{ ksi} \]

Actual Bending Stress

Bending Tensile Stress \( f_{btz} = \left(\frac{Mz}{Iz}\right) \times \bar{Y} = 14.93 \text{ ksi} < 23.8 \text{ ksi} \)

Bending Compressive Stress \( f_{bcz} = 38.7 \text{ ksi} > 23.8 \text{ ksi} \)

Critical stress ratio \( = \frac{38.7 \text{ ksi}}{23.8 \text{ ksi}} = 1.626 \)

Shear

Allowable Shear Stress

\[ a = \text{clear distance between transverse stiffeners (here taken as length)} = 60 \text{ in} \]

\[ h = \text{clear distance flanges of the girder} = D-t_f = 17.01 \text{ in} \]

Thus, \( \frac{a}{h} = 3.527 \) Therefore, \( k = 5.34 + \frac{4.00}{(a/h)^2} = 5.65 \)

\[ t = t_w = 0.44 \text{ inch} \]

If \( Cv > 0.8, \ C_v = \left(\frac{190}{(h/t)}\right) \sqrt{(k/S_y)} = 78.4 \) which is true. Thus, the value of \( C_v \) is taken as 78.4

Allowable shear stress \( = F_v = \left(\frac{F_Y}{2.89}\right) C_v \leq 0.4 F_Y = 14.4 \text{ ksi} \)

Hence allowable shear = 14.4 ksi

Actual Shear

\[ V_y = D t_w = 10.68 \text{ in}^2 \]

\[ f_v = \frac{F_y}{V_y} = 5.805 \text{ ksi} \]

Stress ratio \( = \frac{f_v}{F_v} = 0.403 \)

### V. ASME NF 3000 2004 WShaped

Verify the design of a wide-flange section used for a cantilever beam using the ASME NF 3000 2004 code.

**Details**

The beam is a 10 ft cantilever with a 12.5 kip concentrated load at the free end.

The member is a W16X40 section with Grade A36 steel.

**Validation**

**Maximum shear force (constant shear):** \( V = 12.5 \text{ kips} \)

**Maximum moment (at fixed end):** \( M = 12.5 \text{ kips} \times 120 \text{ in} = 1,500 \text{ in·kips} \)

**Slenderness Ratio**

\[ (KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 18.11 \]

\[ (KL/r)_y = \text{Slenderness Ratio along Y-Axis} = 76.68 \]

Maximum Slenderness Ratio = 76.68 < 240 (Hence OK)

**Bending about Major Axis (Z Axis)**

**Allowable Bending Stress**

\[ b_t/2t_f = 6.862 < 65/(F_y)^{0.5} \text{ [Ref. NF3322.1(d)(2)]} \]

Thus, allowable bending tensile stress = \( F_{btz} = F_y \times [0.79 - 0.002 \times (b_t/2t_f) \times \sqrt{F_y}] = 25.47 \text{ ksi} \)

**Actual Bending Stress**

Bending Tensile Stress = Bending Compressive Stress = \( f_{btz} = f_{bcz} = M_zD/2I_z = 23.17 \text{ ksi} \)

**Stress ratio = 23.16 ksi / 25.47 ksi = 0.909**

**Shear**

**Allowable Shear Stress**

\[ a = \text{clear distance between transverse stiffeners (here taken as length)} = 120 \text{ in} \]

\[ h = \text{clear distance flanges of the girder} = D - 2t_f = 14.91 \text{ in} \]

Thus, \( a/h = 8.05, \text{ Therefore, } k = 5.34 + [4.00/ (a/h)^2] = 5.36 \text{ [Ref. NF3322.6(e)(2)]} \)
\( t = t_w = 0.3 \text{ inch} \)

\[ C_v = 1.475 \]

Allowable shear stress \( F_v = (F_y/2.89)C_v = > 0.4F_y = 14.4 \text{ ksi} \) Hence allowable=14.4ksi

Actual Shear Stress

\[ F_y = 12.5 \text{ kip}, \ V_y = Dt_w = 4.8 \text{ inch}^2 \]

\[ f_v = F_y/V_y = 2.6 \text{ ksi} \]

Stress ratio \( = f_v/F_v = 0.18 \)

Verification Examples
V.09 Steel Design

STAAD.Pro
4241
User Manual
V.ASME NF 3000 2004 STYPE 1 Pipe

Verify the design results an austenitic stainless steel pipe section, designed as per ASME NF 3000 2004.

Details

A beam (beam no. 7 in the model) of length 10 ft is loaded with a uniformly distributed load of 1 kip/ft over the whole span, and axial compressive loads of 100 kip at both ends. The beam is assigned with a steel pipe section of PIPS120 and is designed in accordance with ASME NF3000 2004.

The austenitic stainless steel has a yield strength of 36 ksi, an ultimate rupture strength of 58 ksi, and a modulus of elasticity of 29,000 ksi.

Validation
From the analysis:

\[ F_x = 100.145 \text{ kip} \]
\[ F_y = 5 \text{ kip} \text{ (at ends)} \]
\[ M_z = 97.683 \text{ in} \cdot \text{k} \text{ (at mid-span)} \]
\[ M_y = 10.798 \text{ in} \cdot \text{k} \]

\((KL/r)_z = \text{Slenderness Ratio along Z-Axis} = 27.44 = (KL/r)_y = \text{Slenderness Ratio along Y-Axis < 200 Hence OK (Refer NF-3322.2(c)(1))}\)

**Check Against Axial Compression**

As per clause NF 3322.2(d)(2)(c),

\[ \frac{OD}{t_w} = 12.75/0.35 = 36.429 < 3,300/F_y = 91.667 \]

Since \((KL/r)_y = 27.44 = (kl/r)_z < 120\)

As per NF 3322.1(c)(2)(a),

Allowable compressive stress, \(F_a = F_y \left(0.47 - \frac{kl}{r}444\right) = 14.7 \text{ ksi}\)

Actual compressive stress \(f_a = \frac{F_x}{A_x} = 7.31 \text{ ksi}\)

Ratio = 0.497

**Check Against Bending**

Allowable Stress along Major Axis (Z-Axis):

Since as per clause NF 3322.1(d)(1)(a)(7),

\[ \frac{OD}{t_w} = 12.75/0.35 = 36.429 < 3,300/F_y = 91.67 \]

Thus, allowable bending stress is obtained by treating the section as compact.

\[ F_{bcz} = 0.66 \times F_y = 23.76 \text{ ksi} = F_{btz} \]

Allowable Stress along Minor Axis (Y-Axis):

Here also, allowable stress along minor axis is given as \(F_{by} = 0.66 \times FYLD = 23.8 \text{ ksi} = F_{bcy}\)

Actual Bending Stress along Major Axis (Z-Axis):

\[ M_z = 97.683 \text{ in} \cdot \text{k} \]

Bending Tensile Stress \(f_{btz} = (Mz/Iz) \times (OD/2) = 2.38 \text{ ksi} < 23.8 \text{ ksi}, \text{Hence OK.}\)

Bending Compressive Stress \(f_{bcz} = 2.38 \text{ ksi} < 23.8 \text{ ksi}, \text{Hence safe.}\)

Actual Bending Stress along Minor Axis (Y-Axis):

\[ M_y = 10.798 \text{ in} \cdot \text{k} \]

Bending Tensile Stress \(f_{by} = (Mz/Iz) \times (OD/2) = 0.263 \text{ ksi} < 23.8 \text{ ksi}, \text{Hence OK.}\)

Bending Compressive Stress \(f_{bcy} = 0.263 \text{ ksi} < 23.8 \text{ ksi}, \text{Hence safe.}\)

**Check for Combined Axial Compression and Bending**

\(C_{mz} = C_{my} = 1 \text{ (as provided in the input)}\)

Now, \(f_a = 7.31 \text{ ksi, } F_a = 14.7 \text{ ksi, } F_{bcz} = 2.38 \text{ ksi, } F_{bcy} = 23.8 \text{ ksi, } f_{bcy} = 0.263 \text{ ksi, } F_{bcy} = 23.8 \text{ ksi}\)

Since \(f_a / F_a = 7.31 / 14.7 = 0.497 > 0.15\)
\[ F_{ez}' = \frac{n^2 \times E}{2.15 \times \left( \frac{kl}{r} \right)^2 z} = 176.804 \text{ ksi} \]  
\[ (\text{NF 3322.1(e)(1)} ) \]

\[ F_{ey}' = \frac{n^2 \times E}{2.15 \times \left( \frac{kl}{r} \right)^2 y} = 176.804 \text{ ksi} \]  
\[ (\text{NF 3322.1(e)(1)} ) \]

From Eqn. 20:
\[
\frac{f_a}{F_{a}} + \frac{C_{mz} \times f_{bz}}{F_{ez}} \times F_{bz} + \frac{C_{my} \times F_{by}}{F_{ey}} \times F_{by} = 0.613 < 1, \text{ Hence safe (critical ratio)}
\]

From Eqn. 21:
\[
\frac{f_a}{0.6F_{y}} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = 0.449 < 1, \text{ Hence safe}
\]

**Check Against Shear**

Actual Shear along Major Axis:
\[
V_y = 2 \times \text{OD} \times t_w = 8.925 \text{ in}^2
\]
\[
f_{vy} = 5 \text{ kip} / 8.925 \text{ in}^2 = 0.56 \text{ ksi}
\]
(No shear along minor axis; \( f_{vz} = 0 \))

Allowable Shear:
As per NV 3322.1(b)(1), allowable shear stress, \( F_v = 0.4 \times F_y = 14.4 \text{ ksi} \)

Ratio = 0.039

### V.10 Concrete Design

### V. United States

### V. ACI 318-1999

### V. ACI 318-99 Square Column

Determine the reinforced steel quantity for the square column as per ACI 318-99.
Reference

Problem

\[ P_u = 144 \text{ kips} \]
\[ M_{uz} = 120 \text{ ft·kips} \]
\[ M_{uy} = 54 \text{ ft·kips} \]
\[ f'_c = 3,000 \text{ psi} \]
\[ f_y = 60,000 \text{ psi} \]

Comparison

Table 633: Comparison of results

<table>
<thead>
<tr>
<th>Result Type</th>
<th>Reference</th>
<th>STAAD.Pro</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provided steel area per ACI 318-99(in²)</td>
<td>8.0 (8- #9)</td>
<td>9.0 (4- #14)</td>
<td>none</td>
</tr>
</tbody>
</table>

Note: In the reference book, the axial capacity provided is 141 kips, which is less than the requirement of 144 kips. In the STAAD implementation of the code, any reinforcement arrangement which yields less capacity than the required value is considered unacceptable. This is why STAAD reports a higher required steel than the reference book.

STAAD.Pro reports that it is unable to find a suitable bar arrangement to satisfy the reinforcement requirement per ACI 318-99. However, this does not mean that it is impossible to come up with a bar arrangement. When STAAD looks for a bar arrangement, it uses only bars of the same size. It begins with the bar size corresponding to the parameter \textit{MINMAIN}. If an arrangement is not possible with that bar, it tries with the next larger bar size. If all the permissible bar sizes are exhausted, the program reports that it could not come up with a bar arrangement. However, the user may be able to satisfy the requirement by mixing bars of various diameters. For example, 3 # 11 bars and 2 # 10 bars may satisfy the requirement. The program is not equipped with facilities to come up with such combinations of bar sizes.

In fact, in the reference mentioned for the 1999 edition of ACI 318, the bar arrangement chosen is 2 # 9 and 1 # 8. It proves the point that finding bars of the same diameter is not possible for the 1999 edition based solution.

STAAD Input

The file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\10 Concrete Design\US\ACI\318-2002\ACI 318-02 Rectangular Beam.STD is typically installed with the program.

STAAD.Pro 4262 User Manual
V. ACI 318-2014

V. ACI 318-14 Circular Column

Calculate the axial capacity of a circular column subjected to axial compressive force, given $A_{st}$

**Details**

A circular, cantilever column of length 5ft with an ultimate axial load of 500 kip has the following concrete and steel properties.

- Compressive strength of concrete (normal weight concrete), $f_c = 4,000$ psi
- Yield strength of steel, $f_y = 60,000$ psi
- Clear spacing for outermost bottom reinforcement to bottom face, $C_c = 1.5$ in
- Diameter of column, $D = 20$ in
- Strength reduction factor, $\phi = 0.65$
- Number of #8 bars = 6
- Rebar diameter for #8 bar, $\varnothing d = 1$ in

Factored axial load (axial demand), $P_u = 500$ kip

**Validation**

Gross area of concrete section, $A_g = \pi D^2/4 = 314.159$ in$^2$
Total area of steel reinforcement, \( A_{st} = \left( \pi \frac{D^2}{4} \right) N = 314.159 \text{in}^2 \)

Nominal axial strength at zero eccentricity:

\[
P_0 = 0.85 \times f_c (A_g - A_{st}) + f_y A_{st} = 1.335 \times 10^3 \text{kip}
\]

For tied reinforced column:

\[
P_{n(max)} = 0.8 \times P_0 = 1.068 \times 10^3 \text{kip}
\]

Capacity = \( \phi P_{n(max)} = 694.129 \text{kip} \)

Ratio = \( P_u / \phi P_{n(max)} = 0.72 \)

**Results**

**V. ACI 318-14 Rectangular Column**

Calculate the axial capacity of a rectangular column subjected to axial compressive force, given $A_t$

**Details**

A rectangular, cantilever column of length 5ft with an ultimate axial load of 1,538 kip has the following concrete and steel properties.

- Compressive strength of concrete (normal weight concrete), $f_c = 5,000 \text{ psi}$
- Yield strength of steel, $f_y = 60,000 \text{ psi}$
- Clear spacing for outermost bottom reinforcement to bottom face, $C_c = 1.5 \text{ in}$
- Width of column, $B = 20 \text{ in}$
- Depth of column, $D = 30 \text{ in}$
- Strength reduction factor, $\phi = 0.65$
- Number of #9 bars = 10
- Rebar diameter for #9 bar, $\phi_d = 1.128 \text{ in}$

Factored axial load (axial demand), $P_u = 1,538 \text{ kip}$
**Validation**

Gross area of concrete section, \( A_g = B \times D = 600 \text{ in}^2 \)

Total area of steel reinforcement, \( A_{st} = 10 \text{ in}^2 \)

Nominal axial strength at zero eccentricity:

\[
P_0 = 0.85f_c(A_g - A_{st}) + fyA_{st} = 3.108 \times 10^3 \text{ kip}
\]

For tied reinforced column:

\[
P_{n(max)} = 0.8P_0 = 2.486 \times 10^3 \text{ kip}
\]

Capacity = \( \phi P_{n(max)} = 1,615.9 \text{ kip} \)

Ratio = \( P_u/\phi P_{n(max)} = 0.952 \)

**Results**

**V. ACI 318-14 Square Column**

Calculate the axial capacity of a square column subjected to an axial compressive force, given Ast Details

A square, cantilever column of length 5ft with an ultimate axial load of 998 kip has the following concrete and steel properties.

- Compressive strength of concrete (normal weight concrete), $f_c = 5,000$ psi
- Yield strength of steel, $f_y = 60,000$ psi
- Clear spacing for outermost bottom reinforcement to bottom face, $C_c = 1.5$ in
- Width of column, $B = 20$ in
Depth of column, \( D = 20 \) in
Strength reduction factor, \( \phi = 0.65 \)
Number of \#9 bars = 4
Rebar diameter for \#9 bar, \( \phi_d = 1.128 \) in

Factored axial load (axial demand), \( P_u = 998 \) kip

Validation

Gross area of concrete section, \( A_g = B \times D = 400 \) in²
Total area of steel reinforcement, \( A_{st} = 4 \) in²
Nominal axial strength at zero eccentricity:
\[
P_0 = 0.85 f_c (A_g - A_{st}) + f_y A_{st} = 1.923 \times 10^3 \text{ kip}
\]
For tied reinforced column:
\[
P_{n(max)} = 0.8 P_0 = 1.5384 \times 10^3 \text{ kip}
\]
Capacity = \( \phi P_{n(max)} = 999.96 \) kip
Ratio = \( P_u / \phi P_{n(max)} = 0.998 \)

Results

- Depth of T, \( D = 26 \text{ in} \)
- Thickness of flange, \( T_f = 4 \text{ in} \)
- Thickness of web, \( T_w = 10 \text{ in} \)
- Steel modulus of elasticity, \( E_s = 29,000 \text{ ksi} \)
- Ultimate strain, \( \varepsilon_u = 0.003 \)
- Yield strength of reinforcing steel, \( f_y = 60 \text{ ksi} \)
- Compressive strength of concrete (normal weight concrete), \( f_c = 4,000 \text{ psi} \)
- Clear spacing for outermost bottom reinforcement to bottom face, \( C_c = 1.5 \text{ in} \)
- Strength reduction factor, \( \phi = 0.9 \)
- Rebar diameter for #10 bar, \( \phi d = 1.27 \text{ in} \)

Validation

\[
d = D - C_c - \frac{\phi d}{2} = 23.865
\]
\[
d' = C_c + \frac{\phi d}{2} = 2.135
\]
\[
R_n = \frac{6 \times 400}{\phi \times 0.85 \times f_y \times B_f \times d^2} = 0.122
\]

From Table 7.1 of PCA (ref. 2):

\[
w = \frac{(0.1726 - 0.1648)}{(0.19 - 0.18)} \times (R_n - 0.1648) + 0.18 = 0.147
\]

\[
a = 1.18 \times w \times d = 4.138 > T_f , \text{ hence beam acts as a T}
\]

Compression strength of the flange:

\[
C_f = 0.85 \times f_c \times (B_f + T_w) \times T_f = 136
\]

\[
A_{sf} = C_f f_y = 2.267 \text{ in}^2
\]

this is the required area to equilibrate \( C_f \).

Flexural strength of the flange:

\[
M_{nw} = \frac{6 \times 400}{\phi} - M_{nf} = 4.001 \times 10^{-3} \text{ in} \cdot \text{k}
\]

To check whether this section is tension controlled, refer to PCA Table 7.1 (ref. 2):

\[
R_n = \frac{M_{nw}}{f_c \times T_w \times d^2} = 0.176
\]
\[
w = \frac{(0.1802 - 0.1726)}{(0.2 - 0.19)} \times (R_n - 0.1726) + 0.19 = 0.192
\]
\[ \rho = w_n \frac{f_c}{f_y} = 0.013 < 0.01806 \]

based on PCA Table 6.1 (ref. 2), thus the section is tension controlled.

\[ A_{sw} = \rho \times T_w \times d = 3.06 \text{ in}^2 \]

Assume 6- #10 bars, divided between top and bottom: \( A_{st,tot} = 6 \times 1.27 \text{ in}^2 = 7.62 \text{ in}^2 \)

\[ a_w = \left( A_{st,tot} - A_{sf} \right) \frac{f_y}{0.85 \times f_c \times T_w} = 9.447 \text{in} \]

\[ M_n = (A_{st,tot} - A_{sf}) \times f_y \left( d - \frac{a_w}{2} \right) + A_{sf} \times f_y \times \left( d - \frac{T_f}{2} \right) = 9,258 \text{in}\cdot\text{k} \]

\[ \phi M_n = 8,332 \text{ in} \cdot \text{k} = 694.4 \text{ ft} \cdot \text{k} \]

V. ACI 318-14 Rectangular Beam without Torsion

Design of a doubly reinforced rectangular beam.

Reference
1. ACI 318-14
2. PCA Notes 2011 Example 6.2

Details
To determine the Required Area of Tension and Compression Reinforcement for given Concrete and Steel Properties with Given Factored Moment.

Design of Rectangular Beam with Compression Reinforcement-Doubly Reinforced

A beam cross-section is limited to size 14in X 23 in. Determine the required area of reinforcement for a factored moment Mu= 516 ft-kips. fc= 4000psi, fy=60,000 psi.

Design Properties, available:

Validation
\( d_{cover} = 2.5 \text{ in} \)

Step 1: Check if compression reinforcement is required, using \( Z = 0.9 \).
See table 6-1 of PCA Notes (ref. 2).

\[ b = 14 \text{ in} \]
\[ d = 20.5 \text{ in} \]

**Note:** Assume \( d = d_t \)

\[ M_n = M_u/Z = 573.33 \text{ ft-kip} \]
\[ R_n = M_n / (b^2d^2) = 1.169(10)^3 \text{ psi} \]
\[ R_{nt} = 911 \text{ psi} \]

**Note:** \( R_{nt} = \text{Maximum } R_n \text{ for tension controlled section for that particular grade for concrete.} \)

\[ R_n > R_{nt} \]

Hence, both compression and tension reinforcement is required.

**Step 2:** Determine maximum moment with compression reinforcement,

\[ M_{nt} \]

This condition corresponds to tension controlled limit (\( Z = 0.9 \)).

Depth of neutral axis, \( c = 0.375d_t = 0.375d = 7.687 \text{ in} \)
\[ \beta_1 = 0.85 \text{ (from table 6.1 (ref. 2))} \]
\( a = \beta_1c = 6.534 \text{ in} \)

Compressive force, \( C = 0.85 f_c \cdot a \cdot b = 311.036 \text{ kips} \)

Tension force, \( T = C = 311.036 \text{ kips} \)

Nominal moment strength resisted by the concrete section, without compression reinforcement, \( M_{nt} = T(d - a/2) = 446.669 \text{ ft-kips} \)

Nominal moment strength resisted by the concrete section, with compression reinforcement, \( M_{nc} = M_n \cdot M_{nt} = 126.664 \text{ ft-kips} \)

**Step 3: Determine area of tension steel**

Area of tension steel required, \( A_{s,nt} \), to develop \( M_{nt} \)

\[ A_{s,nt} = \frac{T}{f_y} = 5.184 \text{ in}^2 \]

**Step 4: Determine additional area of tension steel required**

Area of tension steel required, \( A_{s,\text{additional}} \), required to counteract additional moment due to T-C couple.

\[ A_{s,\text{additional}} = \frac{(M_n \cdot M_{nt})}{[f_y \cdot (d - d_{\text{cover}})]} = 1.407 \text{ in}^2 \]

Total tension steel required:

\[ A_s = A_s + A_{s,nt} = 6.591 \text{ in}^2 \]

**Comparison**

Table 642: Comparison of results

<tr>
<td>Area Required (tension) (in²)</td>
<td>6.591</td>
<td>6.355</td>
<td>3.6%</td>
<td>See note (*) below.</td>
</tr>
</tbody>
</table>

**Note:** (*) The required steel calculation above assumes a single layer of bottom bars and the effective depth = 0.375*d*t based on the single bar layer. The reference (ref. 2) calculations only considers a strength design and does not check for the minimum spacing requirements. STAAD.Pro however considers two layers of bars in the design to account for the minimum criteria and hence uses a neutral axis position based on the two bar layers. Hence the minor difference in the steel areas calculated.

V. India

V. IS 13920 2016

V. IS13920 2016-Singly Reinforced Rectangular Beam

Verify the design of a rectangular beam per IS 13920:2016.

Details

A three story, concrete structure is subject to gravity loads only. Beam 59 is to be designed:
Section properties:
- Length of beam, \( L = 3,000 \text{ mm} \) (clear span)
- Width of beam, \( B = 250 \text{ mm} \)
- Depth of beam, \( D = 300 \text{ mm} \)
- Clear cover = 30 mm
- Diameter of main reinforcement = 12 mm
- Diameter of stirrups = 8 mm

Material properties:
- Characteristic strength of concrete, \( f_{ck} = 20 \text{ N/mm}^2 \)
- Yield strength of steel, \( f_y = 415 \text{ N/mm}^2 \)

Loads: total uniform force = 25 kN/m

**Validation**

Effective Depth, \( d = 300 - 30 - 8 - (12/2) = 256 \text{ mm} \)

Depth of Compression Reinforcement, \( d' = 30 + (12/2) + 8 = 44 \text{ mm} \)

Check for Member Size

Width to Depth ratio of the member, \( B/D = 250/300 = 0.833 \) (Clause 6.1.1; IS 13920:2016)
Width of Beam, \( B = 250 \, mm > 200 \, mm \) (Clause 6.1.2; IS 13920:2016)

As per clause 6.1.3 of IS 13920:2016, depth of beam shall not have more than 1/4 of clear span. So, the allowable depth not more than, \( L/4 = 3000/4 = 750 \, mm > 300 \, mm \). Hence ok. (Clause 6.1.3; IS 13920:2016)

Width of the supporting member, \( C2 = 400 \, mm \) and Breadth of the supporting member, \( C1 = 400 \, mm \). So, the width of member, \( B \), shall not exceed smaller of \( (C2) \) and \( (C1) = 400 \, mm \) or \( C2 + \) smaller of \( (C1) \) and \( (C2) = 800 \, mm \). Hence ok. (Clause 6.1.4; IS 13920:2016)

Check for Axial Stress

Axial force from STAAD.Pro analysis, \( F_x = 0.299 \, kN \)

Factored axial compressive stress: \( F_x / (B \times D) = 0.004 < 0.08f_{ck} = 1.6 \), Hence OK (Clause 6.1; IS 13920:2016)

Design for Flexure

Minimum longitudinal reinforcement, \( p_{min} = 0.24 \times \sqrt{f_{ck}} / f_y \times B \times d = 165.5 \, mm^2 \)

Maximum longitudinal reinforcement, \( p_{max} = 0.025 \times B \times d = 1,600 \, mm^2 \)

Limiting moment value, \( M_{z,limit} = 0.138f_{ck} \times B \times d^2 = 45.22 \, kN \cdot m \)

From the STAAD.Pro analysis, \( M_z = 30.28 \, kN \cdot m < M_{z,limit} \) at the start of the member (\( x = 0 \)).

From SP16 table 2 flexure, reinforcement percentage for singly reinforced section:

- Percentage of tension reinforcement \( p_t = 0.583 \)
- Percentage of compression reinforcement \( p_c = 0.292 \)

Reinforcement at Start of Member (\( x = 0 \)): top bars

\[
A_{st, top, a} = 0.583 \times B \times d / 100 = 373.1. \, mm^2
\]

Provide 4 - 12 mm diameter bars. Actual \( A_{st, top} = 4 \times (\pi/4) \times (12)^2 = 452.4 \, mm^2 \)

Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

Reinforcement at Start of Member (\( x = 0 \)): bottom bars

\[
A_{st, bot, a} = 0.292 \times B \times d / 100 = 186.9 \, mm^2
\]

Provide 2 - 12 mm diameter bars. Actual \( A_{st, bot} = 2 \times (\pi/4) \times (12)^2 = 226.2 \, mm^2 \)

Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

From the STAAD.Pro analysis, \( M_z = 24.56 \, kN \cdot m < M_{z,limit} \) at the end of the member (\( x = 3 \, m \)).

From SP16 table 2 flexure, reinforcement percentage for singly reinforced section:

- Percentage of tension reinforcement \( p_t = 0.451 \)
- Percentage of compression reinforcement \( p_c = 0.225 \)

Reinforcement at End of Member (\( x = 3 \, m \)): top bars

\[
A_{st, top, b} = 0.451 \times B \times d / 100 = 288.6 \, mm^2
\]

Provide 3 - 12 mm diameter bars. Actual \( A_{st, top} = 3 \times (\pi/4) \times (12)^2 = 339.3 \, mm^2 \)

Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

Reinforcement at End of Member (\( x = 3 \, m \)): bottom bars

\[
A_{st, bot, b} = 0.225 \times B \times d / 100 = 144 \, mm^2
\]
Provide 2 - 12 mm diameter bars. Actual \( A_{st, bot} = 2 \times (\pi/4) \times (12)\times (12) = 226.2 \text{ mm}^2 \)

Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

As per clause 6.2.4 of IS 13920:2016, any intermediate section, on top or bottom face should have at least 452.4 \( \text{mm}^2/4 = 113.1 \text{ mm}^2 \) of steel as the main reinforcement. So the provided reinforcement satisfies this condition.

**Design for Shear**

Calculation of resistance moment based on the area of steel provided:

Sagging resistance moment at start:

\[
M_{z,as} = 0.87 \times f_y \times A_{st,bot,a} \times d \times [1 - A_{st,bot,a} \times f_y / (B \times d \times f_{ck})] = 19.37 \text{ kN m}
\]

Hogging resistance moment at start:

\[
M_{z,ah} = 0.87 \times f_y \times A_{st,top,a} \times d \times [1 - A_{st,top,a} \times f_y / (B \times d \times f_{ck})] = 35.68 \text{ kN m}
\]

Sagging resistance moment at end:

\[
M_{z,bs} = 0.87 \times f_y \times A_{st,bot,b} \times d \times [1 - A_{st,bot,b} \times f_y / (B \times d \times f_{ck})] = 19.37 \text{ kN m}
\]

Hogging resistance moment at end:

\[
M_{z,bh} = 0.87 \times f_y \times A_{st,top,b} \times d \times [1 - A_{st,top,b} \times f_y / (B \times d \times f_{ck})] = 27.91 \text{ kN m}
\]

Simple shear from gravity load on the span:

\[
V_a = 1.2 \times 25 \text{ kN/m} \times 3/2 = 45 \text{ kN}
\]

Factor shear force as per linear structural analysis in STAAD.Pro, \( F_y = 58.16 \text{ kN} \)

Calculation of shear force due to formation of plastic hinge at both ends of the beam plus the factored gravity load on the span.

For sway to right:

\[
V_{u,ar} = V_a - 1.4 \times (M_{z,as} + M_z \times b \times h/3) = 22.93 \text{ kN}
\]

\[
V_{u,bv} = V_a + 1.4 \times (M_{z,as} + M_z \times b \times h/3) = 67.01 \text{ kN}
\]

For sway to left:

\[
V_{u,al} = V_a + 1.4 \times (M_{z,as} + M_z \times b \times h/3) = 70.69 \text{ kN}
\]

\[
V_{u,bl} = V_a - 1.4 \times (M_{z,as} + M_z \times b \times h/3) = 19.31 \text{ kN}
\]

Design shear force at start: \( V_{ua} = 70.69 \text{ kN} \)

Design shear force at end: \( V_{ub} = 67.01 \text{ kN} \)

Design shear force, \( V_{ua} = 70.69 \text{ kN} \) (Considering clause 6.3.4(c) of IS13920:2016)

Provide 2 legged 8 mm diameter bar. Thus the area of shear reinforcement:

\[
A_v = 2 \times (\pi/4) \times (8)\times (8) = 100.5 \text{ mm}^2
\]

Using the formula from IS 456:2000, the spacing for vertical stirrups is:

\[
S_v = 0.87 \times f_y \times A_{sv} \times d / V_{ub} = 131.4 \text{ mm}
\]

Per clause 6.3.5 of IS13920:2016, the spacing of the links over a length of \( 2d \) at either end of the beam shall be the least of:

- \( d/4 = 64 \text{ mm} \)
b. $6 \times$ bar diameter of the smallest bars = $6 \times 12 = 72$ mm  
c. $100$ mm  
d. $S_v = 131$ mm

Thus, it should be not greater than $64$ mm. Therefore, provide 2 legged - 8 mm links @ 60 mm center to center at left and right end over a length of $2d = 512$ mm.

Per Clause 6.3.5.2 of IS13920:2016, the spacing of the stirrups in the mid-span shall not exceed $d/2 = 128$ mm. Thus, use a spacing of 125 mm elsewhere.

V.IS13920 2016-Doubly Reinforced Rectangular Beam

Verify the design of a rectangular beam per IS 13920:2016.

Details

A three story, concrete structure is subject to gravity loads only. Beam 59 is to be designed:

Length of beam, \( L = 3,000 \, \text{mm} \) (clear span)
Width of beam, \( B = 250 \, \text{mm} \)
Depth of beam, \( D = 300 \, \text{mm} \)
Clear cover = 30 \, \text{mm}
Diameter of main reinforcement = 16 \, \text{mm}
Diameter of stirrups = 8 \, \text{mm}
Material properties:

- Characteristic strength of concrete, $f_{ck} = 20 \text{ N/mm}^2$
- Yield strength of steel, $f_y = 415 \text{ N/mm}^2$

Loads: total uniform force = $50 \text{ kN/m}$

**Validation**

Effective Depth, $d = 300 - 30 - 8 - (16/2) = 254 \text{ mm}$

Depth of Compression Reinforcement, $d' = 30 + (16/2) + 8 = 46 \text{ mm}$

*Check for Member Size*

Width to Depth ratio of the member, $B/D = 250/300 = 0.833$ (Clause 6.1.1; IS 13920:2016)

Width of Beam, $B = 250 \text{ mm} > 200 \text{ mm}$ (Clause 6.1.2; IS 13920:2016)

As per clause 6.1.3 of IS 13920:2016, depth of beam shall not have more than $1/4$ of clear span. So, the allowable depth not more than, $L/4 = 3000/4 = 750 \text{ mm} > 300 \text{ mm}$. Hence ok. (Clause 6.1.3; IS 13920:2016)

Width of the supporting member, $C_2 = 400 \text{ mm}$ and Breadth of the supporting member, $C_1 = 400 \text{ mm}$. So, the width of member, $B$, shall not exceed smaller of $(C_2)$ and $(C_1) = 400 \text{ mm} or (C_2 + smaller of (C_1) and (C_2) = 800 \text{ mm}$. Hence ok. (Clause 6.1.4; IS 13920:2016)

Axial force from STAAD.Pro analysis, $F_x = 6.805 \text{ kN}$

Factored axial compressive stress: $F_x / (B \times D) = 0.09 < 0.08 f_{ck} = 1.6$, Hence OK (Clause 6.1; IS 13920:2016)

**Design for Flexure**

Minimum longitudinal reinforcement, $p_{min} = 0.24 \times (f_{ck} / f_y) \times B \times d = 164.2 \text{ mm}^2$

Maximum longitudinal reinforcement, $p_{max} = 0.025 \times B \times d = 1,588 \text{ mm}^2$

Limiting moment value, $M_{z,limit} = 0.138 f_{ck} \times B \times d^2 = 44.52 \text{ kN} \cdot \text{m}$

From the STAAD.Pro analysis, $M_z = 55.44 \text{ kN} \cdot \text{m} > M_{z,limit}$ at the start of the member ($x = 0$).

So, the actual moment is greater than limiting moment then the section will be design as doubly reinforced section.

From SP16 table 50 flexure, reinforcement percentage for doubly reinforced section:

- Percentage of tension reinforcement $p_t = 1.19$
- Percentage of compression reinforcement $p_c = 0.595$

**Reinforcement at Start of Member ($x = 0$): top bars**

$$A_{st, top.a} = 1.19 \times B \times d / 100 = 755.7 \text{ mm}^2$$

Provide 4 - 16 mm diameter bars. Actual $A_{st, top} = 4 \times (\pi/4) \times (16)^2 = 804.2 \text{ mm}^2$

Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

**Reinforcement at Start of Member ($x = 0$): bottom bars**

$$A_{st, bot.a} = 0.595 \times B \times d / 100 = 377.8 \text{ mm}^2$$

Provide 2 - 16 mm diameter bars. Actual $A_{st, bot} = 2 \times (\pi/4) \times (16)^2 = 402.1 \text{ mm}^2$

Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.
From the STAAD.Pro analysis, \( M_z = 54.11 \text{ kN·m} > M_{z,\text{limit}} \) at the end of the member (\( x = 3 \text{ m} \)).

From SP16 table 50 flexure, reinforcement percentage for doubly reinforced section

Percentage of tension reinforcement \( p_t = 1.161 \) and compression reinforcement \( p_c = 0.581 \).

Reinforcement at End of Member (\( x = 3 \text{ m} \)):

- **Top bars**
  \[ A_{st,\text{top, b}} = 1.161 \times B \times d / 100 = 737.4 \text{ mm}^2 \]
  
  Provide 4 - 16 mm diameter bars. Actual \( A_{st, \text{top}} = 3 \times (\pi/4) \times (16)^2 = 804.2 \text{ mm}^2 \)

  Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

- **Bottom bars**
  \[ A_{st,\text{bot, b}} = 0.225 \times B \times d / 100 = 368.7 \text{ mm}^2 \]
  
  Provide 2 - 16 mm diameter bars. Actual \( A_{st, \text{bot}} = 2 \times (\pi/4) \times (16)^2 = 402.1 \text{ mm}^2 \)

  Thus, clause 6.2.1(b) and 6.2.2 of IS 13920:2016 are satisfied.

As per clause 6.2.4 of IS 13920:2016, any intermediate section, on top or bottom face should have at least \( 804.2 \text{ mm}^2 / 4 = 201.1 \text{ mm}^2 \) of steel as the main reinforcement. So the provided reinforcement satisfies this condition.

**Design for Shear**

Calculation of resistance moment based on the area of steel provided:

Sagging resistance moment at start:

\[ M_{z,\text{as}} = 0.87 \times f_y \times A_{st,\text{bot, a}} \times d \times \left[ 1 - A_{st,\text{bot, a}} \times f_y / (B \times d \times f_{ck}) \right] = 32.03 \text{ kN·m} \]

Hogging resistance moment at start:

\[ M_{z,\text{ah}} = 0.87 \times f_y \times A_{st,\text{top, a}} \times d \times \left[ 1 - A_{st,\text{top, a}} \times f_y / (B \times d \times f_{ck}) \right] = 54.37 \text{ kN·m} \]

Sagging resistance moment at end:

\[ M_{z,\text{bs}} = 0.87 \times f_y \times A_{st,\text{bot, b}} \times d \times \left[ 1 - A_{st,\text{bot, b}} \times f_y / (B \times d \times f_{ck}) \right] = 32.03 \text{ kN·m} \]

Hogging resistance moment at end:

\[ M_{z,\text{bh}} = 0.87 \times f_y \times A_{st,\text{top, b}} \times d \times \left[ 1 - A_{st,\text{top, b}} \times f_y / (B \times d \times f_{ck}) \right] = 54.37 \text{ kN·m} \]

Simple shear from gravity load on the span:

\[ V_a = 1.2 \times 50 \text{ kN/m} \times 3/2 = 90 \text{ kN} \]

Factor shear force as per linear structural analysis in STAAD.Pro, \( F_y = 112.9 \text{ kN} \)

Calculation of shear force due to formation of plastic hinge at both ends of the beam plus the factored gravity load on the span.

For sway to right:

\[ V_{u,\text{ar}} = V_a - 1.4 \times (M_{z,\text{as}} + M_z \times b \times h/3) = 49.68 \text{ kN} \]

\[ V_{u,\text{br}} = V_a + 1.4 \times (M_{z,\text{as}} + M_z \times b \times h/3) = 130.3 \text{ kN} \]

For sway to left:

\[ V_{u,\text{al}} = V_a + 1.4 \times (M_{z,\text{as}} + M_z \times b \times h/3) = 130.3 \text{ kN} \]

\[ V_{u,\text{bl}} = V_a - 1.4 \times (M_{z,\text{as}} + M_z \times b \times h/3) = 49.68 \text{ kN} \]

Design shear force at start: \( V_{ua} = 130.3 \text{ kN} \)
Design shear force at end: \( V_{ub} = 130.3 \text{ kN} \)

Design shear force, \( V_{ua} = 130.3 \text{ kN} \) (Considering clause 6.3.4(c) of IS13920:2016)

Provide 2 legged 8 mm diameter bar. Thus the area of shear reinforcement:

\[
A_v = 2 \times \left( \frac{\pi}{4} \right) \times 8^2 = 100.5 \text{ mm}^2
\]

Using the formula from IS 456:2000, the spacing for vertical stirrups is:

\[
S_v = 0.87 \times f_y \times A_{sv} \times d / V_{ua} = 70.7 \text{ mm}
\]

Per clause 6.3.5 of IS13920:2016, the spacing of the links over a length of \( 2d \) at either end of the beam shall be the least of:

a. \( d/4 = 64 \text{ mm} \)

b. \( 6 \times \text{bar diameter of the smallest bars} = 6 \times 16 = 96 \text{ mm} \)

c. \( 100 \text{ mm} \)

d. \( S_v = 71 \text{ mm} \)

Thus, it should be not greater than 64 mm. Therefore, provide 2 legged - 8 mm links @ 60 mm center to center at left and right end over a length of \( 2d = 508 \text{ mm} \).

Per Clause 6.3.5.2 of IS13920:2016, the spacing of the stirrups in the mid-span shall not exceed \( d/2 = 127 \text{ mm} \). Thus, use a spacing of 125 mm elsewhere.

*** Design Shear Force at Section 0.0 is 133.30 KN.***

- Clause 6.3.3 of IS-13920

*** Design Shear Force at Section 3000.0 is 133.30 KN.***

- Clause 6.3.3 of IS-13920

Note:
Moment of resistance is calculated based on the area of steel provided. If area of steel provided is much higher compared to area of steel required moment of resistance will increase which may increase design shear force.

This section contains various examples of analytical models, physical models, macro script files, and more which can be helpful in familiarizing yourself with aspects of STAAD.Pro features.

This UK and US sections include examples of various problems that can be solved using the STAAD engine. These examples represent various structural analyses and design problems commonly encountered by structural engineers.

The example models included here along with many other files are installed with the program by default. The default location for these files is C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\.

**Note:** The option to include these files is selected during the product installation.

### EX. Building Planner Example Models

The following models are included when STAAD.Pro is installed.

These files are located in the C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Building Planner\ folder (default location).

**Table 651: Building Planner examples installed with the program**

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circular Building.std</td>
<td>This model demonstrates how circular shaped non-orthogonal building can be created accurately in the Building Planner workflow. This is a complex model and with the use of plan in dxf format received from architect (included in this folder), the entire plan is created. With the use of tools like Copy, Paste, and Mirror, the symmetrical circular structure can be created by just using one half of the model created in dxf. Columns with different beta angle can be modeled effectively and accurately using the Building Planner.</td>
</tr>
<tr>
<td>Typical Ground +3 Story Building.std</td>
<td>This model is of a typical 4 story building having 3 different plans: Plinth Plan, Typical Plan, and Roof Plan. The Plinth plan consist of beam and column without slabs. The RoofPlan has wall loads only for parapet walls.</td>
</tr>
</tbody>
</table>
Application Examples

EX. CIS/2 Example Models

The following models are included when STAAD.Pro is installed.

These files are located in the
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\CIS2\folder (default location).

Table 652: CIS/2 examples installed with the program

EX. Physical Model Examples
The following models are included when STAAD.Pro is installed.
These files are located in the C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Physical Models\ folder (default location).

Table 655: Physical Model examples installed with the program

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area Loads Example.std</td>
<td>This physical model example showcases how Area loads is applied by creating a panel on the stories. This area load gets assigned to the adjoining members (on the panel’s boundary edges) in terms of member distributed loads. Also, the model contains diaphragm defined for each of the floors. The structure is subjected to load categorized as Dead and Live Load groups which are then referenced in the load cases and consequently load combination.</td>
</tr>
<tr>
<td>Cabled stayed Tower Example.std</td>
<td>This example shows the modeling of a tower with cable stayed and fixed at their end. The self-weight of the cables is ignored by setting the ‘Ignore Self Weight’ property of the member. After analysis for this reason of ignoring the self-weight, it will show applied self-weight is less than the total weight of all. Also, Member Tension Only attribute is set for these cables. The columns are set with standard Pipe sections whereas the cables are set with circular sections. The structure is subjected Dead and wind load in the form of lateral loads in load groups and referenced in load cases and consequently load combination.</td>
</tr>
<tr>
<td>Concrete Building Example.std</td>
<td>This physical model example shows a concrete building with steel columns. The concrete slabs are created as single physical surface for each of the floors and for the lift well with openings for the doors and windows. The slabs are subjected to distributed load categorized in the dead and live load case directly as a load item. Also, linear load combination is defined.</td>
</tr>
<tr>
<td>Steel Framed Warehouse Example.std</td>
<td>This physical model example showcases a typical warehouse with standard steel sections of various shapes. Notice that the truss chords are defined as continuous members. The members are assigned with offsets in start and end. The structure is subjected to dead and live load on the frame structure in the form of self-weight and distributed loads. Also, linear load combination is defined.</td>
</tr>
<tr>
<td>Storehouse with Walls Example.std</td>
<td>This physical model example showcases a typical storehouse with standard steel sections of various shapes. The walls of the storehouse are created as physical surfaces. The structure is subjected to dead loads on the frame structure in the form of self-weight and point loads. Also, linear load combination is defined.</td>
</tr>
</tbody>
</table>

Note: The file name of the STAAD input file is listed. Other files associated with this model are included with the same base file name in this folder using different file extensions.

EX. American Design Examples
EX. US-1 Plane Frame with Steel Design

After one analysis, member selection is requested. Since member sizes change during the member selection, another analysis is done followed by final code checking to verify that the final sizes meet the requirements of the code based on the latest analysis results.

This problem is installed with the program by default to C: \Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-1 Plane Frame with Steel Design.STD when you install the program.

where:

L = 15 ft, H1 = 20 ft, H2 = 15 ft, and H3 = 9 ft
WLx = 0.6 k/ft, WLy = 1.0 k/ft, RL = 0.9 k/ft, LL = 1.2 k/ft, P1 = 35 kips, P2 = 15 kips
Members 1, 3, & 4 are a W14x90, Members 5, 6, & 7 are a W21x50, Member 2 is a W10x49, Members 8 through 13 are a W18x35. All other members comprising the truss are a L4x4x1/4

Actual input is shown in bold lettering followed by explanation.

STAAD PLANE EXAMPLE PROBLEM NO. 1

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

UNIT FT KIP

Defines the input units for the data that follows.

JOINT COORDINATES

1 0. 0. ; 2 30 0 ; 3 0 20 0 6 30 20 0
7 0 35 ; 8 30 35 ; 9 7.5 35 ; 10 22.5 35.
11 15 35 ; 12 5. 38. ; 13 25 38
14 10 41 ; 15 20 41 ; 16 15 44

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCE

1 1 3 ; 2 3 7 ; 3 2 6 ; 4 6 8 ; 5 3 4
6 4 5 ; 7 5 6 ; 8 7 12 ; 9 12 14
10 14 16 ; 11 15 16 ; 12 13 15 ; 13 8 13
14 9 12 ; 15 9 14 ; 16 11 14 ; 17 11 15
18 10 15 ; 19 10 13 ; 20 7 9
21 9 11 ; 22 10 11 ; 23 8 10

Defines the members by the joints to which they are connected.

MEMBER PROPERTY AMERICAN

1 3 4 TABLE ST W14X90 ; 2 TA ST W10X49
5 6 7 TA ST W21X50 ; 8 TO 13 TA ST W18X35
14 TO 23 TA ST L40404

Member properties are from the British steel table. The term ST stands for standard single section.

MEMB TRUSS

14 TO 23

The above command defines that members 14 through 23 are of type truss. This means that these members can carry only axial tension/compression and no moments.

MEMB RELEASE

5 START MZ

Member 5 has local moment-z (MZ) released at the start joint. This means that the member cannot carry any moment-z (i.e., strong axis moment) at node 3.

UNIT INCH

DEFINE MATERIAL START
ISOTROPIC STEEL
E 29000
POISSON 0.3
DENSITY 0.000283
ALPHA 6e-006
DAMP 0.03

Application Examples
EX. American Design Examples
The `DEFINE MATERIAL` command initiates input for a material definition, which can later be assigned to all members. STAAD.Pro has several built-in material definitions, including the ISOTROPIC STEEL material used here. The length unit is changed from FEET to INCH to facilitate the input in familiar units.

```plaintext
CONSTANTS
BETA 90.0 MEMB 3 4
MATERIAL STEEL ALL
UNIT FT
```

The `CONSTANT` command initiates input for material constants or material definition references. The `BETA` command specifies that members 3 and 4 are rotated by 90 degrees around their own longitudinal axis. See the `4.3 Relationship Between Global and Local Coordinates` (on page 2301) for the definition of the beta angle.

A fixed support is located at joint 1 and a pinned support at joint 2.

```plaintext
SUPPORT
1 FIXED ; 2 PINNED
```

The above `PRINT` commands are self-explanatory. The `LIST` option restricts the print output to the members listed.

```plaintext
LOADING 1 DEAD AND LIVE LOAD
SELFWEIGHT Y -1.0
```

One of the components of load case 1 is the selfweight of the structure acting in the global Y direction with a factor of -1.0. Since global Y is vertically upward, the factor of -1.0 indicates that this load will act downwards.

```plaintext
JOINT LOAD
4 5 FY -15. ; 11 FY -35.
```

Load 1 contains joint loads also. FY indicates that the load is a force in the global Y direction.

```plaintext
MEMB LOAD
8 TO 13 UNI Y -0.9 ; 6 UNI GY -1.2
```

Load 1 contains member loads also. GY indicates that the load is in the global Y direction while Y indicates local Y direction. The term UNI stands for uniformly distributed load. Loads are applied on members 6, and 8 to 13.

```plaintext
CALCULATE RAYLEIGH FREQUENCY
```

The above command at the end of load case 1, is an instruction to perform a natural frequency calculation based on the Rayleigh method using the data in the above load case.

```plaintext
LOADING 2 WIND FROM LEFT
MEMBER LOAD
1 2 UNI GX 0.6 ; 8 TO 10 UNI Y -1.
```

Load case 2 is initiated and contains several member loads.

```plaintext
* 1/3 RD INCREASE IS ACCOMPLISHED BY 75% LOAD
LOAD COMB 3 75 PERCENT DL LL WL
1 0.75 2 0.75
```
The above command identifies a combination load (case no. 3) with a title. The second line provides the load cases and their respective factors used for the load combination.

**Note:** Any line beginning with an asterisk (*) character is treated as a comment line.

**PERFORM ANALYSIS**

This command instructs the program to proceed with the analysis.

**LOAD LIST 1 3**

The above command activates load cases 1 and 3 only for the commands to follow. This also means that load case 2 will be made inactive.

**PRINT MEMBER FORCES**
**PRINT SUPPORT REACTION**

The above PRINT commands are self-explanatory. Also note that all the forces and reactions will be printed for load cases 1 and 3 only.

**PARAMETER**

- **CODE AISC UNIFIED**
- **NSF 0.85 ALL**
- **BEAM 1.0 ALL**
- **KY 1.2 MEMB 3 4**
- **RATIO 0.9 ALL**
- **PROFILE W14 MEMB 1 3 4**

The PARAMETER command is used to specify steel design parameters such as net section factor (NSF), effective length factor for bending about the minor axis (KY), etc. Information on these parameters can be obtained from the manual where the implementation of the code is explained. The BEAM parameter is specified to perform design at every 1/12th point along the member length, which is also the default. The RATIO parameter specifies that the ratio of actual loading over section capacity should not exceed 0.9.

**SELECT ALL**

The above command instructs the program to select the most economic section for all the members based on the results of the analysis.

**GROUP MEMB 1 3 4**
**GROUP MEMB 5 6 7**
**GROUP MEMB 8 TO 13**
**GROUP MEMB 14 TO 23**

Although the program selects the most economical section for all members, it is not always practical to use many different sizes in one structure. Grouping is a procedure by which the cross section which has the largest value for the specified attribute, which in this case is the default and hence the AREA, from among the associated member list, is assigned to all members in the list. Hence, the cross sections for members 1, 3 and 4 are replaced with the one with the largest area from among the three.

**PERFORM ANALYSIS**

As a result of the selection and grouping, the member sizes are no longer the same as the ones used in the original analysis. Hence, it is necessary to reanalyze the structure using the new properties to get new values of forces in the members.

**PARAMETER**

- **BEAM 1.0 ALL**
- **RATIO 1.0 ALL**
- **TRACK 1.0 ALL**
A new set of values are now provided for the above parameters. The actual load to member capacity \textbf{RATIO} has been redefined as 1.0. The \textbf{TRACK} parameter tells the program to print out the design results to the intermediate level of descriptively.

\begin{verbatim}
CHECK CODE ALL
\end{verbatim}

With the above command, the latest member sizes with the latest analysis results are checked to verify that they satisfy the \textbf{CODE} specifications.

\begin{verbatim}
STEEL TAKE OFF
\end{verbatim}

This command instructs the program to list the length and weight of all the different member sizes.

\begin{verbatim}
FINISH
\end{verbatim}

This command terminates the STAAD run.

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.

*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

</tbody>
</table>

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that
produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase
based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◊about◊ the relevant axis (X/Y), while
the results for shear are reported as being for shear forces ◊along◊ the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along
the X axis.

*** ABBREVIATIONS ***:

****************************************************************************
ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted).
**NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

### Torsional moment.

### Bending moment about minor axis.

### Bending moment about major axis.

---

### DESIGN MESSAGES:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.

2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.

3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.

**E.g**: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

---

### ABBREVIATIONS:

- **F-T-B** = Flexural-Torsional Buckling
- **L-T-B** = Lateral-Torsional Buckling
- **F-L-B** = Flange Local Buckling
- **W-L-B** = Web Local Buckling
- **L-L-B** = Leg Local Buckling
- **C-F-Y** = Compression Flange Yielding
- **T-F-Y** = Tension Flange Yielding

EX. US-2 Area Load Generation on Floor Structure

A floor structure (bound by global X-Z axis) made up of steel beams is subjected to area load (i.e., load/area of floor). Load generation based on one-way distribution is illustrated in this example.

In the case of loads such as joint loads and member loads, the magnitude and direction of the load at the applicable joints and members is directly known from the input. However, the area load is a different sort of load where a load intensity on the given area has to be converted to joint and member loads. The calculations required to perform this conversion are done only during the analysis. Consequently, the loads generated from the AREA LOAD command can be viewed only after the analysis is completed.

This problem is installed with the program by default to C:sers\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-2 Area Load Generation on Floor Structure.STD when you install the program.
Figure 455: Example Problem No. 2

Where:

W1 = 5 ft, W2 = 3.5 ft, W3 = 5.5 ft, L1 = 7 ft, L2 = 15 ft, L3 = 10 ft

Actual input is shown in bold lettering followed by explanation.

STAAD FLOOR A FLOOR FRAME DESIGN WITH AREA LOAD

Every input has to start with the term STAAD. The term FLOOR signifies that the structure is a floor structure and the structure is in the x – z plane.

UNIT FT KIP

Defines the input units for the data that follows.

JOINT COORDINATES
1 0. 0. 0. 5 20. 0. 0. ; 7 5. 0. 10.
8 10. 0. 10. ; 9 13. 0. 10. ; 10 15. 0. 10. ; 11 16.5 0. 10.
12 20. 0. 10. ; 13 0. 0. 25. ; 14 5. 0. 25. ; 15 11. 0. 25.
16 16.5 0. 25 ; 17 20. 0. 25. 18 0. 0. 28.
19 20. 0. 28. ; 20 0. 0. 35. ; 21 20. 0. 35.
Joint numbers followed by X, Y and Z coordinates are provided above. Since this is a floor structure, the Y coordinates are all the same (in this case, zero). Joints between 1 and 5 (i.e., 2, 3, 4) are generated in the first line of input, taking advantage of the equal spacing between the joints (see TR.11 Joint Coordinates Specification on page 2425 for more information).

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

```
MEMBER INCIDENCES
1 1 2 4 ; 5 7 8 9 ; 10 13 14 13 ; 14 18 19
15 20 21 ; 16 18 20 ; 17 13 18 ; 18 1 13
19 7 14 ; 20 2 7 ; 21 9 15
22 3 8 ; 23 11 16 ; 24 4 10 ; 25 19 21
26 17 19 ; 27 12 17 ; 28 5 12
```

Defines the members by the joints to which they are connected.

```
MEMB PROP AMERICAN
1 TO 28 TABLE ST W12X26
```

Member properties are specified from the AISC steel table. In this case, the W12X26 section is chosen. The term ST stands for standard single section.

```
* MEMBERS WITH PINNED ENDS ARE RELEASED FOR MZ
MEMB RELEASE
1 5 10 14 15 18 26 20 TO 24 START MZ
4 9 13 14 15 18 25 19 21 TO 24 END MZ
```

The first set of members (1 5 10 etc) have local moment-z (MZ) released at the start joint. This means that these members cannot carry any moment-z (i.e., strong axis moment) at the start joint. The second set of members have MZ released at the end joints.

**Note:** Any line beginning with an asterisk (*) character is treated as a comment line.

END DEFINE MATERIAL
UNIT FT
```

Define the material properties for steel. The units are changed to inches and then back to feet in order to facilitate inputing the values in familiar units.

```
CONSTANT
MATERIAL STEEL ALL
```

The CONSTANT command instructs the program to use the defined steel material for all members.

```
SUPPORT
1 5 13 17 20 21 FIXED
```

A fixed support has been specified at the above joints.

```
LOADING 1 300 POUNDS PER SFT DL+LL
```
Load case 1 is initiated followed by a title.

FLOOR LOAD
YRANGE -0.5 0.5 FLOAD -0.30

All members within a range of -0.5 feet to 0.5 feet in the global Y direction (which is the entire floor of this model) are subjected to an floor load of 0.3 kips/sq.ft. The program converts area loads into individual member loads.

PERFORM ANALYSIS PRINT LOAD DATA

This command instructs the program to proceed with the analysis. The PRINT LOAD DATA command is specified to obtain a listing of the member loads which were generated from the FLOOR LOAD.

PARAMETERS
CODE AISC UNIFIED
BEAM 1 ALL
DMAX 2.0 ALL
DMIN 1.0 ALL
UNT 1.0 ALL
UNB 1.0 ALL

The PARAMETER command is used to specify steel design parameters (See Table 2.1 in Section 2.4 of the Technical Reference manual on page 1409). Design is to be performed per the specifications of the AISC ASD Code. The BEAM parameter is specified to perform design at every 1/12th point along the member length. DMAX and DMIN specify maximum and minimum depth limitations to be used during member selection. UNT and UNB are used to specify unsupported length for top and bottom flange to be used for calculation of allowable bending stress.

SELECT MEMB 2 6 11 14 15 16 18 19 21 23 24 27

The above command instructs the program to select the most economical section from the British steel table for the members listed.

FINISH

The FINISH command terminates the STAAD run.

STEEL DESIGN

A FLOOR FRAME DESIGN WITH AREA LOAD

STAAD.PRO MEMBER SELECTION - AISC 360-16 LRFD (V1.1)
ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted).

*** NOTE : AISC 360-16 Design Statement for STAAD.Pro. ***

*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16 design results are reported in AISC 360-16 code axis convention.

</tbody>
</table>

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis. E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** ABBREVIATIONS ***:

EX. US-3 Soil Springs for Portal Frame

A portal frame type steel structure is sitting on concrete footings. The soil is to be considered as an elastic foundation. The value of soil subgrade reaction is known from which spring constants are calculated by multiplying the subgrade reaction by the tributary area of each modeled spring.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-3 Soil Springs for Portal Frame.STD when you install the program.

![Diagram of portal frame](image)

*Figure 456: Example Problem No. 3*

Where:

- \( B = 20 \text{ ft}, \ H = 10 \text{ ft}, \ F_1 = 4 \text{ ft}, \ F_2 = 8 \text{ ft} \)
- \( P = 5 \text{ kips}, \ w = 3 \text{ kips/ft} \)
- Soil Subgrade Reaction = 250 kips/ft\(^3\)

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE PORTAL ON FOOTING FOUNDATION**

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

**UNIT FT KIPS**

 Defines the input units for the data that follows.

**JOINT COORDINATES**

<table>

</table>

The first two lines define member properties as prismatic (PRIS) followed by depth (YD) and width (ZD) values. The program will calculate the properties necessary to perform the analysis. See G.6.1 Prismatic Properties (on page 2323) for additional information. Member properties for the remaining members are chosen from the British steel table. The term ST stands for standard single section.

* E FOR STEEL IS 29,000 AND FOR CONCRETE 3000
UNIT INCHES
DEFINE MATERIAL START
ISOTROPIC STEEL
E 29000
The CONSTANT command initiates input for material constants like modulus of elasticity, Density, and Poisson's ratio. The length unit is changed from FT to INCH to facilitate the input in familiar units.

**Note:** Any line beginning with an asterisk (*) character is treated as a comment line.

The supports for the structure are specified above. The first set of joints are supports restrained in all directions except global moment-z (MZ). Also, a spring having a spring constant of 4,000 kip/ft is provided in the global Y direction at these nodes. The second set is similar to the former except for a different value of the spring constant.

Load case 1 is initiated followed by a title. The selfweight of the structure is specified as acting in the global Y direction with a -1.0 factor. Since global Y is vertically upwards, the -1.0 factor indicates that this load will act downwards.

Load 1 contains joint loads also. FX indicates that the load is a force in the global X direction.

Load 1 contains member loads also. GY indicates that the load acts in the global Y direction. The term UNI stands for uniformly distributed load, and is applied on members 7 and 8, acting downwards.

This command instructs the program to proceed with the analysis.
The above PRINT command instructs the program to print analysis results which include joint displacements, member forces and support reactions.

FINISH

This command terminates the STAAD run.

EX. US-4 Inactive Members in a Braced Frame

This example is a typical case of a load-dependent structure where the structural condition changes for different load cases. In this example, different bracing members are made inactive for different load cases. This is done to prevent these members from carrying any compressive forces.

This problem is installed with the program by default to 
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-4 Inactive Members in a Braced Frame.STD when you install the program.

Where:

\[ L_1 = 180 \text{ in.}, L_2 = 240 \text{ in.} \]
\[ P_1 = 15 \text{ kips}, P_2 = 30 \text{ kips} \]

Actual input is shown in bold lettering followed by explanation.

```
STAAD PLANE
* A PLANE FRAME STRUCTURE WITH TENSION BRACING
```
Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

UNIT INCH KIP

Defines the input units for the data that follows.

SET NL 3

This structure has to be analyzed for three primary load cases. Consequently, the modeling of our problem requires us to define three sets of data, with each set containing a load case and an associated analysis command. Also, the members which get switched off in the analysis for any load case have to be restored for the analysis for the subsequent load case. To accommodate these requirements, it is necessary to have two commands, one called SET NL and the other called CHANGE. The SET NL command is used above to indicate the total number of primary load cases that the file contains. The CHANGE command will come in later (after the PERFORM ANALYSIS command).

JOINT COORDINATES
1 0 0 0 3
4 0 180. 0 6
7 240. 360. 0

Joint number followed by X, Y and Z coordinates are provided above. Since this is a plane structure, the Z coordinates are given as all zeros.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCE
1 1 4 2 ; 3 5 7 ; 4 3 6 ; 5 6 8 ; 6 4 5 7
8 7 8 ; 9 1 5 ; 10 2 4 ; 11 3 5 ; 12 2 6
13 6 7 ; 14 5 8

Defines the members by the joints to which they are connected.

MEMBER TRUSS
9 TO 14

The preceding command defines that members 9 through 14 are of type truss. This means these members can only carry axial tension/compression and no moments.

MEMBER PROP AMERICAN
1 TO 5 TABLE ST W12X26
6  7  8 TA ST W18X35
9 TO 14 TA LD L50505

Properties for all members are assigned from the American (AISC) steel table. The word ST stands for standard single section. The word LD stands for long leg back-to-back double angle. Since the spacing between the two angles of the double angle is not provided, it is assumed to be 0.0.

DEFINE MATERIAL START
ISOTROPIC STEEL

DENSITY 283e-006
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 36 FU 58 RY 1.5 RT 1.2
END DEFINE MATERIAL
Define the material properties for steel. The units are changed to inches and then back to feet in order to facilitate inputing the values in familiar units.

```
CONSTANTS
MATERIAL STEEL ALL
```

The CONSTANT command initiates input for material definitions.

```
SUPPORT
1 2 3 PINNED
```

Pinned supports are specified at Joints 1, 2 and 3. The word PINNED signifies that no moments will be carried by these supports.

```
INACTIVE MEMBERS 9 TO 14
```

The preceding command makes the listed members inactive. The stiffness contribution of these members will not be considered in the analysis till they are made active again.

UNIT FT
LOADING 1 DEAD AND LIVE LOAD
```

Load case 1 is initiated followed by a title. The length UNIT is changed from INCH to FT for input values which follow.

```
MEMBER LOAD
6 8 UNI GY -1.0
7 UNI GY -1.5
```

Load 1 contains member loads. GY indicates that the load acts in the global Y direction. The word UNI stands for uniformly distributed load. The load is applied on members 6, 7, and 8.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis. It is worth noting that members 9 to 14 will not be used in this analysis since they were declared inactive earlier. In other words, for dead and live load, the bracing members are not used to carry any load.

```
CHANGES
```

The members inactivated earlier are restored using the CHANGE command.

```
INACTIVE MEMBERS 10 11 13
```

A new set of members are made inactive. The stiffness contribution from these members will not be used in the analysis till they are made active again. They have been inactivated to prevent them from being subject to compressive forces for the next load case.

```
LOADING 2 WIND FROM LEFT
```

Load case 2 is initiated followed by a title.

```
JOINT LOAD
4 FX 30 ; 7 FX 15
```

Load 2 contains joint loads. FX indicates that the load is a force in the global X direction. Nodes 4 and 7 are subjected to the loads.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis. The analysis will be performed for load case 2 only.
The above CHANGE command is an instruction to re-activate all inactive members.

| INACTIVE MEMBERS 9 12 14 |

Members 9, 12 and 14 are made inactive. The stiffness contribution of these members will not be used in the analysis till they are made active again. They have been inactivated to prevent them from being subject to compressive forces for the next load case.

| LOADING 3 WIND FROM RIGHT |

Load case 3 is initiated followed by a title.

| JOINT LOAD |
| 6 FX -30 ; 8 FX -15 |

Load 3 contains joint loads at nodes 6 and 8. FX indicates that the load is a force in the global X direction. The negative numbers (-30 and -15) indicate that the load is acting along the negative global X direction.

| LOAD COMBINATION 4 |
| 1 0.75 2 0.75 |
| LOAD COMBINATION 5 |
| 1 0.75 3 0.75 |

Load combination case 4 involves the algebraic summation of the results of load cases 1 and 2 after multiplying each by a factor of 0.75. For load combinations, the program simply gathers the results of the component primary cases, factors them appropriately, and combines them algebraically. Thus, an analysis in the real sense of the term (multiplying the inverted stiffness matrix by the load vector) is not carried out for load combination cases. Load combination case 5 combines the results of load cases 1 and 3.

| PERFORM ANALYSIS |

This command instructs the program to proceed with the analysis. Only primary load case 3 will be considered for this analysis. (As explained earlier, a combination case is not truly analyzed for, but handled using other means.)

| CHANGE |

The above CHANGE command will re-activate all inactive members.

| LOAD LIST ALL |

At the end of any analysis, only those load cases for which the analysis was done most recently, are recognized as the "active" load cases. The LOAD LIST ALL command enables all the load cases in the structure to be made active for further processing.

| PRINT MEMBER FORCES |

The preceding PRINT command is an instruction to produce a report, in the output file, of the member end forces.

| LOAD LIST 1 4 5 |

A LOAD LIST command is a means of instructing the program to use only the listed load cases for further processing.

| PARAMETER |
| CODE AISC UNIFIED |
| BEAM 1.0 ALL |
| UNT 6.0 ALL |
| UNB 6.0 ALL |
| KY 0.5 ALL |
The PARAMETER command is used to specify the steel design parameters (information on these parameters can be obtained from the manual where the implementation of the code is explained). Design will be done according to the specifications of the AISC ASD Code. The BEAM parameter is specified to perform design at every 1/12th point along the member length. UNT and UNB represent the unsupported length of the flanges to be used for calculation of allowable bending stress. KY 0.5 ALL sets the effective length factor for column buckling about the local Y-axis to be 0.5 for ALL members.

CHECK CODE ALL

The above command instructs the program to perform a check to determine how you defined member sizes along with the latest analysis results meet the code requirements.

FINISH

This command terminates the STAAD run.

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.

*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

</table>

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being \( \phi \) about \( \phi \) the relevant axis (X/Y), while the results for shear are reported as being for shear forces \( \phi \) along \( \phi \) the axis. E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** ABBREVIATIONS ***:

- F-T-B = Flexural-Torsional Buckling
- L-T-B = Lateral-Torsional Buckling
- F-L-B = Flange Local Buckling
- W-L-B = Web Local Buckling
- L-L-B = Leg Local Buckling
- C-F-Y = Compression Flange Yielding
- T-F-Y = Tension Flange Yielding

EX. US-5 Support Settlement on a Portal Frame

This example demonstrates the application of support displacement load (also known as a sinking support) on a space frame structure.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-5 Support Settlement on a Portal Frame.STD when you install the program.

Where:

\[ L_1 = 10 \text{ ft} \]
\[ L_2 = 20 \text{ ft} \]

Actual input is shown in bold lettering followed by explanation.

### STAAD SPACE TEST FOR SUPPORT DISPLACEMENT

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

### UNITS KIP FEET

Defines the input units for the data that follows.

### JOINT COORDINATES

<table>
<thead>
<tr>
<th>Joint</th>
<th>X</th>

<td>10.0</td>
<td>20.0</td>
</tr>
<tr>
<td>6</td>
<td>20.0</td>
<td>0.0</td>
<td>20.0</td>
</tr>
</tbody>
</table>

Joint number followed by X, Y and Z coordinates are provided above.
Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 2 3</td>
</tr>
<tr>
<td>4 3 5 ; 5 5 6</td>
</tr>
</tbody>
</table>

Defines the members by the joints to which they are connected.

<table>
<thead>
<tr>
<th>UNIT INCH MEMB PROP</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 5 PRIS AX 10. IZ 300. IY 300. IX 10.</td>
</tr>
</tbody>
</table>

Member properties have been defined above using the PRISMATIC attribute. Values of AX (area), IZ (moment of inertia about major axis), IY (moment of inertia about minor axis) and IX (torsional constant) are provided in INCH unit.

```
DEFINE MATERIAL START
  ISOTROPIC STEEL
  E 29000.
  POISSON 0.3
  DENSITY 283e-006
  ALPHA 6e-006
  DAMP 0.03
  TYPE STEEL
  STRENGTH FY 36 FU 58 RY 1.5 RT 1.2
END DEFINE MATERIAL
```

Material are defined using the DEFINE MATERIAL command and then assigned using the CONSTANT command.

<table>
<thead>
<tr>
<th>SUPPORT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 4 6 FIXED</td>
</tr>
</tbody>
</table>

Joints 1, 4 and 6 are fixed supports.

<table>
<thead>
<tr>
<th>LOADING 1 SINKING SUPPORT</th>
</tr>
</thead>
</table>

Load case 1 is initiated followed by a title.

<table>
<thead>
<tr>
<th>SUPPORT DISPLACEMENT LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 FY -0.50</td>
</tr>
</tbody>
</table>

Load 1 is a support displacement load which is also commonly known as a sinking support. FY signifies that the support settlement is in the global Y direction and the value of this settlement is 0.5 inch downward.

<table>
<thead>
<tr>
<th>PERFORM ANALYSIS</th>
</tr>
</thead>
</table>

This command instructs the program to proceed with the analysis.

<table>
<thead>
<tr>
<th>PRINT ANALYSIS RESULTS</th>
</tr>
</thead>
</table>

The above PRINT command instructs the program to print joint displacements, support reactions and member forces.

<table>
<thead>
<tr>
<th>FINISH</th>
</tr>
</thead>
</table>

This command terminates the STAAD run.

STAAD.Pro 4406 User Manual
EX. US-6 Prestress and Poststress Loading

This is an example of prestress loading in a plane frame structure.

It covers two situations:

1. From the member on which it is applied, the prestressing effect is transmitted to the rest of the structure through the connecting members (known in the program as PRESTRESS load).

2. The prestressing effect is experienced by the member(s) alone and not transmitted to the rest of the structure (known in the program as POSTSTRESS load).

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-6 Prestress and Poststress Loading.STD when you install the program.
Figure 459: Example Problem No. 6

Where:

L1 = 15 ft
L2 = 20 ft
L3 = 40 ft

Actual input is shown in bold lettering followed by explanation.

STAAD PLANE FRAME WITH PRESTRESSING LOAD

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

UNIT KIP FT

Defines the input units for the data that follows.

JOINT COORD
1  0.  0.  ;  2  40.  0.  ;  3  0.  20.  ;  4  40.  20.  
5  0.  35.  ;  6  40.  35.  ;  7  0.  50.  ;  8  40.  50.  

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCE
1 1 3 ; 2 3 5 ; 3 5 7 ; 4 2 4 ; 5 4 6
6 6 8 ; 7 3 4 ; 8 5 6 ; 9 7 8
Defines the members by the joints to which they are connected.

```
SUPPORT
  1  2  FIXED
```

The supports at joints 1 and 2 are defined to be fixed supports.

```
MEMB PROP
  1  TO  9  PRI  AX  2.2  IZ  1.0
```

Member properties are provided using the PRI (prismatic) attribute. Values of area (AX) and moment of inertia about the major axis (IZ) are provided.

```
UNIT INCH
DEFINE MATERIAL START
  ISOTROPIC  CONCRETE
  E  3000.
  POISSON  0.17
  DENSITY  8.7e-005
  ALPHA  5e-006
  DAMP  0.05
  G  1346.15
  TYPE  CONCRETE
  STRENGTH  FCU  4
END DEFINE MATERIAL
```

The `DEFINE MATERIAL` command is used to specify material properties and the `CONSTANT` command is used to assign the material to all members. Length unit is changed from FT to INCH to facilitate the input.

```
LOADING 1  PRESTRESSING LOAD
MEMBER  PRESTRESS
  7  8  FORCE  300.  ES  3.  EM -12.  EE  3.
```

Load case 1 is initiated along with an accompanying title. Load 1 contains PRESTRESS load. Members 7 and 8 have a cable force of 300 kips. The location of the cable at the start (ES) and end (EE) is 3 inches above the center of gravity while at the middle (EM) it is 12 inches below the c.g. The assumptions and facts associated with this type of loading are explained in section 1 of the Technical Reference Manual.

```
LOADING 2  POSTSTRESSING LOAD
MEMBER  POSTSTRESS
  7  8  FORCE  300.  ES  3.  EM -12.  EE  3.
```

Load case 2 is initiated along with an accompanying title. Load 2 is a POSTSTRESS load. Members 7 and 8 have cable force of 300 kips. The location of the cable is the same as in load case 1. For a difference between PRESTRESS loading and POSTSTRESS loading, as well as additional information about both types of loads, please refer to section 1 of the Technical Reference Manual.

```
PERFORM  ANALYSIS
```

This command instructs the program to perform the analysis.

```
UNIT  FT
PRINT  ANALYSIS  RESULT
```

The preceding command is an instruction to write joint displacements, support reactions and member forces in the output file. The preceding line causes the results to be written in the length unit of feet.

```
FINISH
```

This command terminates the STAAD run.

EX. US-7 Modeling Offset Connections in a Frame

This example illustrates modeling of structures with offset connections. Offset connections arise when the center lines of the connected members do not intersect at the connection point. The connection eccentricity behaves as a rigid link and is modeled through specification of MEMBER OFFSETS.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-7 Modeling Offset Connections in a Frame.STD when you install the program.

![Figure 460: Example Problem No. 7](image-url)
Where:

- \( L_1 = 15 \text{ ft} \)
- \( L_2 = 20 \text{ ft} \)
- \( L_3 = 7 \text{ in} \)
- \( L_4 = 6 \text{ in} \)

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE TEST FOR MEMBER OFFSETS**

Every input has to start with the term **STAAD**. The term **PLANE** signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

**UNIT FT KIP**

Defines the input units for the data that follows.

**JOINT COORD**

1 0. 0.; 2 20. 0.; 3 0. 15.
4 20. 15.; 5 0. 30.; 6 20. 30.

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

**SUPPORT**

1 2 PINNED

Pinned supports are specified at joints 1 and 2. The word **PINNED** signifies that no moments will be carried by these supports.

**MEMB INCI**

1 1 3 2; 3 3 5 4
5 3 4; 6 5 6; 7 1 4

Defines the members by the joints to which they are connected.

**MEMB PROP AMERICAN**

1 TO 4 TABLE ST W14X90
5 6 TA ST W12X26
7 TA LD L80608

Member properties are assigned from the American (AISC) steel table for all members. The word **ST** stands for standard single section. **LD** stands for long leg back-to-back double angle.

**Note:** This problem uses a steel size from an older AISC catalog. In order to use this shape for analysis and design, you must select **AISCSections** or **aiscsections_all_editions** database for use as the **American** section profile table.

**UNIT INCH**

**MEMB OFFSET**

5 6 START 7.0 0.0 0.0
5 6 END -7.0 0.0 0.0
7 END -7.0 -6.0 0.0
The preceding specification states that an OFFSET is located at the START/END joint of the members. The X, Y, and Z global coordinates of the offset distance from the corresponding incident joint are also provided. These attributes are applied to members 5, 6, and 7.

EX. US-8 Concrete Design for a Space Frame

In this example, concrete design is performed on some members of a space frame structure. Design calculations consist of computation of reinforcement for beams and columns. Secondary moments on the columns are obtained through the means of a P-Delta analysis.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-8 Concrete Design for a Space Frame.STD when you install the program.
The above example represents a space frame, and the members are made of concrete. The input in the next page will show the dimensions of the members.

Two load cases, namely one for dead plus live load and another with dead, live and wind load, are considered in the design.

Actual input is shown in bold lettering followed by explanation.

**STAAD SPACE FRAME WITH CONCRETE DESIGN**

Every input has to start with the term **STAAD**. The word **SPACE** signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

**UNIT KIP FT**

Defines the input units for the data that follows.

**JOINT COORDINATE**

1  0  0  0 ; 2  18  0  0 ; 3  38  0  0
4  0  0  24 ; 5  18  0  24 ; 6  38  0  24
7  0  12  0 ; 8  18  12  0 ; 9  38  12  0
10 0  12  24 ; 11  18  12  24 ; 12  38  12  24
13  18  24  0 ; 14  38  24  0 ; 15  18  24  24

Joint number followed by X, Y and Z coordinates are provided above.
Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCE

1 1 7 ; 2 4 10 ; 3 2 8 ; 4 8 13

Defines the members by the joints to which they are connected.

UNIT INCH
MEMB PROP
1 2 PRISMATIC YD 12.0 IZ 509. IY 509. IX 1018.
3 TO 10 PR YD 12.0 ZD 12.0 IZ 864. IY 864. IX 1279.
11 TO 21 PR YD 21.0 ZD 16.0 IZ 5788. IY 2953. IX 6497.

All member properties are provided using the PRISMATIC option. YD and ZD stand for depth and width. If ZD is not provided, a circular shape with diameter = YD is assumed for that cross section. All properties required for the analysis, such as, Area, Moments of Inertia, etc. are calculated automatically from these dimensions unless these are explicitly defined. For this particular example, moments of inertia (IZ, IY) and torsional constant (IX) are provided, so these will not be recalculated. The IX, IY, and IZ values provided in this example are only half the values of a full section to account for the fact that the full moments of inertia will not be effective due to cracking of concrete. Clause 10.11.1 of ACI 318-99 offers some guidelines on the amount of reduction to be applied on the gross section moment of inertia for beams, columns, walls and slabs to account for cracking.

The DEFINE MATERIAL command is used to define material properties for concrete. The CONSTANT command is used to assign this to all members.

SUPPORT
1 TO 6 FIXED

Joints 1 to 6 are fixed supports.

LOAD 1 (1.4DL + 1.7LL)

Load case 1 is initiated followed by a title.

SELF Y -1.4

The selfweight of the structure is applied in the global Y direction with a -1.4 factor. Since global Y is vertically upward, the negative factor indicates that this load will act downwards.
Load 1 contains member loads also. \( Y \) indicates that the load is in the local \( Y \) direction. The word \textit{UNI} stands for uniformly distributed load.

| Load 2 \( 0.75 \times (1.4DL + 1.7LL + 1.7WL) \) |

Load case 2 is initiated followed by a title.

| \text{REPEAT LOAD} | 1 \( 0.75 \) |

The preceding command will gather the load data values from load case 1, multiply them with a factor of 0.75 and utilize the resulting values in load 2.

| \text{Joint Load} | 15 16 \( FZ \) 8.5 |
| 11 \( FZ \) 20.0 |
| 12 \( FZ \) 16.0 |
| 10 \( FZ \) 8.5 |

Load 2 contains some additional joint loads also. \( FZ \) indicates that the load is a force in the global \( Z \) direction.

| \text{PDELTA ANALYSIS} |

This command instructs the program to proceed with the analysis. The analysis type is \textit{P-DELTA} indicating that second-order effects are to be calculated.

| \text{Print Forces List} 2 5 9 14 16 |

Member end forces are printed using the above \textit{PRINT} commands. The \textit{LIST} option restricts the print output to the members listed.

| \text{Start Concrete Design} |

The above command initiates a concrete design.

| \text{Code ACI} |
| \text{Track 1.0 Memb 14} |
| \text{Track 2.0 Memb 16} |
| \text{MaxMain 11 All} |

The values for the concrete design parameters are defined in the above commands. Design is performed per the \textit{ACI 318 Code}. The \textit{Track} value dictates the extent of design related information that should appear in the output. \textit{MaxMain} indicates that the maximum size of main reinforcement is the \#11 bar. These parameters are described in the manual where American concrete design related information is available.

| \text{Design Beam} 14 16 |

The above command instructs the program to design beams 14 and 16 for flexure, shear, and torsion.

| \text{Design Column} 2 5 |

The above command instructs the program to design columns 2 and 5 for axial load and biaxial bending.

| \text{End Concrete Design} |

This will end the concrete design.

| \text{Finish} |

This command terminates the STAAD run.

60. END CONCRETE DESIGN

61. FINISH

******** END OF THE STAAD.Pro RUN ********

**** DATE= APR 14, 2019 TIME= 22:57:35 ****
EX. US-9 Modeling Slabs and Shear Walls Using Finite Elements

The space frame structure in this example consists of frame members and finite elements (plates). The finite element part is used to model floor slabs and a shear wall. Concrete design of an element is performed.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-9 Modeling Slabs and Shear Walls Using Finite Elements.STD when you install the program.

Figure 462: Example Problem No. 9

Actual input is shown in bold lettering followed by explanation.

```
STAAD SPACE
  * EXAMPLE PROBLEM WITH FRAME MEMBERS AND FINITE ELEMENTS

UNIT FEET KIP

The units for the data that follows are specified above.

JOINT COORD
  1 0 0 0 ; 2 0 0 20
```
The joint numbers and their coordinates are defined through the above set of commands. The automatic
generation facility has been used several times in the above lines. See section 5.11 of the Technical Reference
Manual on page 2425 where the joint coordinate generation facilities are described.

The member incidences are defined through the above set of commands. For some members, the member
number followed by the start and end joint numbers are defined. In other cases, STAAD's automatic generation
facilities are utilized. Section 5 of the Technical Reference Manual describes these facilities in detail.

The above lines define the nodes of super-elements. Super-elements are plate/shell surfaces from which a
number of individual plate/shell elements can be generated. In this case, the points describe the outer corners of
a slab and that of a shear wall. Our goal is to define the slab and the wall as several plate/shell elements.

The above lines form the instructions to generate individual 4-noded elements from the super-element profiles.
For example, the command MESH ABCD 4 4 means that STAAD.Pro has to generate 16 elements from the
surface formed by the points A, B, C and D with 4 elements along the edges AB & CD and 4 elements along the edges BC & DA.

<table>
<thead>
<tr>
<th>MEMB PROP</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 40 PRIS YD 1 ZD 1</td>
</tr>
</tbody>
</table>

Members 1 to 40 are defined as a rectangular prismatic section with 1 ft depth and 1 ft width.

<table>
<thead>
<tr>
<th>ELEM PROP</th>
</tr>
</thead>
<tbody>
<tr>
<td>41 TO 88 TH 0.5</td>
</tr>
</tbody>
</table>

Elements 41 to 88 are defined to be 0.5 ft thick.

<tr>
<td>PRINT SUPP REAC</td>
</tr>
</tbody>
</table>
Support reactions, members forces and element stresses are printed for load cases 1 and 3.

The above set of command form the instructions to STAAD to perform a concrete design on element 47. Design is done according to the ACI 318 code. Note that design will consist only of flexural reinforcement calculations in the longitudinal and transverse directions of the elements for the moments MX and MY.

The STAAD run is terminated.

EX. US-10 Finite Element Model for a Rectangular Tank

A tank structure is modeled with four-noded plate elements. Water pressure from inside is used as loading for the tank. Reinforcement calculations have been done for some elements.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-10 Finite Element Model for a Rectangular Tank.STD when you install the program.

Figure 463: Tank Model
Application Examples

EX. American Design Examples

Figure 464: Deflected Shape

Actual input is shown in bold lettering followed by explanation.

<table>
<thead>
<tr>
<th>STAAD SPACE FINITE ELEMENT MODEL OF TANK</th>
</tr>
</thead>
<tbody>
<tr>
<td>* STRUCTURE</td>
</tr>
</tbody>
</table>

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame (3-D) structure.

<table>
<thead>
<tr>
<th>UNITS FEET KIPS</th>
</tr>
</thead>
</table>

Defines the input units for the data that follows.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0. 0. 0. 5 0. 20. 0.</td>
</tr>
<tr>
<td>REPEAT 4 5. 0. 0.</td>
</tr>
<tr>
<td>REPEAT 4 0. 0. 5.</td>
</tr>
<tr>
<td>REPEAT 4 -5. 0. 0.</td>
</tr>
<tr>
<td>REPEAT 3 0. 0. -5.</td>
</tr>
<tr>
<td>81 5. 0. 5. 83 5. 0. 15.</td>
</tr>
<tr>
<td>REPEAT 2 5. 0. 0.</td>
</tr>
</tbody>
</table>

Joint number followed by X, Y and Z coordinates are provided above. The REPEAT command generates joint coordinates by repeating the pattern of the previous line of joint coordinates. The number following the REPEAT command is the number of repetitions to be carried out. This is followed by X, Y and Z coordinate increments. See section 5.11 of the Technical Reference Manual (on page 2425).

<table>
<thead>
<tr>
<th>ELEMENT INCIDENCES</th>

<tr>
<td>76 86 89 46 51</td>
</tr>
<tr>
<td>77 16 21 26 87</td>
</tr>
</tbody>
</table>
Element connectivities are input as above by providing the element number followed by joint numbers defining the element. The REPEAT command generates element incidences by repeating the pattern of the previous line of element nodes. The number following the REPEAT command is the number of repetitions to be carried out and that is followed by element and joint number increments. See section 5.12 of the Technical Reference Manual (on page 2428).

UNIT INCHES
ELEMENT PROPERTIES
1 TO 80 TH 8.0

Element properties are provided by specifying that the elements are 8.0 inches THick.

DEFINE MATERIAL ISOTROPIC CONCRETE
E 3000.
POISSON 0.17
DENSITY 8.7e-005
ALPHA 5e-006
DAMP 0.05
G 1346.15
TYPE CONCRETE
STRENGTH FCU 4
END DEFINE MATERIAL
CONSTANTS
MATERIAL CONCRETE ALL

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

SUPPORT
1 TO 76 BY 5 81 TO 89 PINNED

Pinned supports are specified at the joints listed above. No moments will be carried by these supports. The expression 1 TO 76 BY 5 means 1, 6, 11, etc. up to 76.

UNIT FT
LOAD 1
ELEMENT LOAD
4 TO 64 BY 4 PR 1.
3 TO 63 BY 4 PR 2.
2 TO 62 BY 4 PR 3.
1 TO 61 BY 4 PR 4.

Load case 1 is initiated. It consists of element loads in the form of uniform pressure(indicated by PR) acting along the local z-axis.

PERFORM ANALYSIS

This command instructs the program to proceed with the analysis.

UNIT INCHES
PRINT JOINT DISPLACEMENTS LIST 5 25 45 65

The joint displacement values for the listed nodes will be reported in the output file as a result of the above command.

PRINT ELEM FORCE LIST 13 16
PRINT ELEM STRESS LIST 9 12
Two types of results are requested for elements. The first one requests the nodal point forces in the global axes directions to be reported for elements 13 and 16. The second one requests element centroid stresses in the element local axes directions to be reported for elements 9 and 12. These results will appear in a tabular form in the output file.

```
START CONCRETE DESIGN
```

The above command initiates concrete design.

```
CODE ACI
DESIGN SLAB  9  12
```

Slabs (i.e., elements) 9 and 12 will be designed and the reinforcement requirements obtained. In STAAD, elements are typically designed for the moments MX and MY at the centroid of the element.

```
END CONCRETE DESIGN
```

Terminates the concrete design operation.

```
FINISH
```

This command terminates the STAAD run.

EX. US-11 Response Spectrum Analysis of a Frame

Dynamic analysis (Response Spectrum) is performed for a steel structure. Results of a static and dynamic analysis are combined. The combined results are then used for steel design.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-11 Response Spectrum Analysis of a Frame.STD when you install the program.
Where:

$L_1 = 10$ ft, $L_2 = 20$ ft

$w = 1.5$ k/ft

$P_1 = 5.0$ kips, $P_2 = 7.5$ kips

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE RESPONSE SPECTRUM ANALYSIS**

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

**UNIT FEET KIPS**

Defines the input units for the data that follows.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 0 ; 2 20 0 0</td>
</tr>
<tr>
<td>3 0 10 0 ; 4 20 10 0</td>
</tr>
<tr>
<td>5 0 20 0 ; 6 20 20 0</td>
</tr>
</tbody>
</table>

Joint number followed by X, Y and Z coordinates are provided above. Since this is a plane structure, the Z coordinates are all the same, in this case, zeros.
**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 3 ; 2 2 4 ; 3 3 5 ; 4 4 6</td>
</tr>
<tr>
<td>5 3 4 ; 6 5 6</td>
</tr>
</tbody>
</table>

Defines the members by the joints to which they are connected.

<table>
<thead>
<tr>
<th>MEMBER PROPERTIES AMERICAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 4 TA ST W10X33</td>
</tr>
<tr>
<td>5 TA ST W12X40</td>
</tr>
<tr>
<td>6 TA ST W8X40</td>
</tr>
</tbody>
</table>

Properties for all members are assigned from the American (AISC) steel table. The word ST stands for standard single section.

<table>
<thead>
<tr>
<th>SUPPORTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 FIXED</td>
</tr>
</tbody>
</table>

Fixed supports are specified at joints 1 and 2.

<table>
<thead>
<tr>
<th>UNIT INCH</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINE MATERIAL START</td>
</tr>
<tr>
<td>ISOTROPIC STEEL</td>
</tr>
<tr>
<td>E 29000.</td>
</tr>
<tr>
<td>POISSON 0.3</td>
</tr>
<tr>
<td>DENSITY 283e-006</td>
</tr>
<tr>
<td>ALPHA 6e-006</td>
</tr>
<tr>

</tr>
<tr>
<td>END DEFINE MATERIAL</td>
</tr>
<tr>
<td>CONSTANT</td>
</tr>
<tr>
<td>MATERIAL STEEL ALL</td>
</tr>
</tbody>
</table>

Material constants such as E (modulus of elasticity), Poisson’s ratio and density (DEN) are specified above. Length unit is changed from FT to INCH to facilitate the input.

<table>
<thead>
<tr>
<th>CUT OFF MODE SHAPE 2</th>
</tr>
</thead>
</table>

The number of mode shapes to be considered in dynamic analysis is set to 2. Without the above command, this will be set to the default. See section 5.30.1 of the Technical Reference Manual (on page 2539).

<table>
<thead>
<tr>
<th>* LOAD 1 WILL BE STATIC LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIT FEET</td>
</tr>
<tr>
<td>LOAD 1 DEAD AND LIVE LOADS</td>
</tr>
</tbody>
</table>

Load case 1 is initiated followed by a title. Prior to this, the length unit is changed to METER for specifying distributed member loads. A line starting with an asterisk (*) mark indicates a comment line.

<table>
<thead>
<tr>
<th>SELFWEIGHT Y -1.0</th>
</tr>
</thead>
</table>

The above command indicates that the selfweight of the structure acting in the global Y direction is part of this load case. The factor of -1.0 is meant to indicate that the load acts opposite to the positive direction of global Y, hence downwards.
Load 1 contains member loads also. GY indicates that the load is in the global Y direction while Y indicates local Y direction. The word UNI stands for uniformly distributed load while CON stands for concentrated load. GY is followed by the value of the load and the distance at which it is applied.

* NEXT LOAD WILL BE RESPONSE SPECTRUM LOAD
  * WITH MASSES PROVIDED IN TERMS OF LOAD.
LOAD 2 SEISMIC LOADING

The two lines which begin with the asterisk are comment lines which tell us the purpose of the next load case. Load case 2 is then initiated along with an optional title. This will be a dynamic load case. Permanent masses will be provided in the form of loads. These masses (in terms of loads) will be considered for the eigensolution. Internally, the program converts these loads to masses, hence it is best to specify them as absolute values (without a negative sign). Also, the direction (X, Y, Z etc.) of the loads will correspond to the dynamic degrees of freedom in which the masses are capable of vibrating. In a PLANE frame, only X and Y directions need to be considered. In a SPACE frame, masses (loads) should be provided in all three (X, Y and Z) directions if they are active along all three. The user has the freedom to restrict one or more directions.

SELFWEIGHT X 1.0
SELFWEIGHT Y 1.0

The above commands indicate that the selfweight of the structure acting in the global X and Y directions with a factor of 1.0 is taken into consideration for the mass matrix.

MEMBER LOADS

<table>
<thead>
<tr>
<th>Load</th>
<th>Load Type</th>
<th>Gx Value</th>
<th>Gy Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>CON</td>
<td>5.0</td>
<td>6.0</td>
</tr>
<tr>
<td>5</td>
<td>CON</td>
<td>5.0</td>
<td>6.0</td>
</tr>
<tr>
<td>5</td>
<td>CON</td>
<td>7.5</td>
<td>10.0</td>
</tr>
<tr>
<td>5</td>
<td>CON</td>
<td>7.5</td>
<td>10.0</td>
</tr>
<tr>
<td>5</td>
<td>CON</td>
<td>5.0</td>
<td>14.0</td>
</tr>
<tr>
<td>5</td>
<td>CON</td>
<td>5.0</td>
<td>14.0</td>
</tr>
</tbody>
</table>

The mass matrix will also consist of terms derived from the above member loads. GX and GY indicate that the load, and hence the resulting mass, is capable of vibration along the global X and Y directions. The word CON stands for concentrated load. Concentrated forces of 5, 7.5, and 5 kips are located at 6ft, 10ft and 14ft from the start of member 5.

SPECTRUM CQC IBC 2012 X 1.0 ACC DAMP 0.05
ZIP 92806 SITE CLASS D TL 12.0

The SPECTRUM command specifies a 2012 International Building Code / ASCE 7-10 seismic response spectrum load. The modal responses will be combined using the CQC method. Here, the spectrum effect is in the global X direction with a factor of 1.0. IBC 2012 response spectra are always given in terms of acceleration (ACC). A damping ratio of 0.05 (5%) is used. The second line then gives the location and site class values (using the US ZIP postal code and IBC/ASCE site class) along with the long period transition time.

LOAD LIST  1  3  4
PARAMETER CODE AISC UNIFIED SELECT ALL

A steel design in the form of a member selection is performed based on the rules of the American Code. Only the member forces resulting from load cases 1, 3 and 4 will be considered for these calculations.

FINISH

This command terminates the STAAD run.

EX. US-12 Moving Load Generation on a Bridge Deck

This example demonstrates generation of load cases for the type of loading known as a moving load. This type of loading occurs classically when the load-causing units move on the structure, as in the case of trucks on a bridge deck. The mobile loads are discretized into several individual immobile load cases at discrete positions. During this process, enormous number of load cases may be created resulting in plenty of output to be sorted. To avoid looking into a lot of output, the maximum force envelope is requested for a few specific members.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-12 Moving Load Generation on a Bridge Deck.STD when you install the program.
Where:

L1 = 30 ft
L2 = 5 ft

Actual input is shown in bold lettering followed by explanation.

<table>
<thead>
<tr>
<th>STAAD FLOOR A SIMPLE BRIDGE DECK</th>
</tr>
</thead>
</table>

Every input has to start with the term STAAD. The word FLOOR signifies that the structure is a floor structure and the geometry is defined through X and Z axis.

| UNITS FEET KIPS |
Defines the input units for the data that follows.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 0 6 25 0 0</td>
</tr>
<tr>
<td>R 5 0 0 30</td>
</tr>
</tbody>
</table>

Joint number followed by X, Y, and Z coordinates are provided above. Since this is a floor structure, the Y coordinates are all the same (in this case, zero). The first line generates joints 1 through 6. With the repeat (R) command, the coordinates of the next 30 joints are generated by repeating the pattern of the coordinates of the first 6 joints 5 times with X, Y and Z increments of 0,0, and 9 respectively.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 7 6</td>
</tr>
<tr>
<td>7 1 2 11</td>
</tr>
<tr>
<td>R A 4 11 6</td>
</tr>
<tr>
<td>56 31 32 60</td>
</tr>
</tbody>
</table>

Defines the members by the joints to which they are connected. The fourth number indicates the final member number up to which they will be generated. Repeat all (abbreviated as R A) will create members by repeating the member incidence pattern of the previous 11 members. The number of repetitions to be carried out is provided after the RA command and the member increment and joint increment are defined as 11 and 6 respectively. The fifth line of input defines the member incidences for members 56 to 60.

<table>
<thead>
<tr>
<th>MEMBER PROPERTIES AMERICAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 60 TA ST W12X26</td>
</tr>
</tbody>
</table>

Member properties are assigned from the American AISC table for all members. The word ST stands for standard single section.

<table>
<thead>
<tr>
<th>SUPPORTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 6 31 TO 36 PINNED</td>
</tr>
</tbody>
</table>

Pinned supports are specified at the above joints. A pinned support is one which can resist only translational forces.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The input units are changed from FT to INCH. The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

<table>
<thead>
<tr>
<th>UNIT FEET KIP</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINE MOVING LOAD</td>
</tr>
<tr>
<td>TYPE 1 LOAD 20. 20. 10. DISTANCE 10. 5. WIDTH 10.0</td>
</tr>
</tbody>
</table>

The characteristics of the vehicle are defined above in METER and KNS units. The above lines represent the first out of two sets of data required in moving load generation. The type number (1) is a label for identification of the load-causing unit, such as a truck. Three axles (20 20 10) are specified with the LOAD command. The spacing between the axles in the direction of movement (longitudinal direction) is specified after the DISTANCE
command. WIDTH is the spacing in the transverse direction, that is, it is the distance between the 2 prongs of an axle of the truck.

LOAD 1

Load case 1 is initiated.

SELF Y -1.0

Selfweight of the structure acting in the negative (due to the factor -1.0) global Y direction is the only component of load case 1.

LOAD GENERATION 10
TYPE 1 7.5 0. 0. ZI 10.

This constitutes the second of the two sets of data required for moving load generation. 10 load cases are generated using the Type 1 vehicle whose characteristics were described earlier. For the first of these load cases, the X, Y and Z location of the reference load (see section 5.31.1 of the Technical Reference Manual (on page 2541)) have been specified after the command TYPE 1. The Z Increment of 10ft denotes that the vehicle moves along the Z direction and the individual positions which are 10ft apart will be used to generate the remaining 9 load cases.

As seen in Section 5.31.1 of the Technical Reference manual, the reference wheel is on the last axle. The first load case which is generated will be the one for which the first axle is just about to enter the bridge. The last load case should be the one for which the last axle is just about to exit the bridge. Thus, the total distance travelled by the reference load will be the length of the vehicle (distance from first axle to last axle) plus the span of the bridge. In this problem, that comes to

$$(10+5) + 150 = 165 \text{ feet}.$$ 

This example uses 10 ft increments and generates 10 load cases.

However, if you want the vehicle to move forward in 15 feet increments (each 15 foot increment will create a discrete position of the truck on the bridge), it would required $(165/15)+1 = 12$ cases to be generated.

PERFORM ANALYSIS PRINT LOAD

The above command instructs the program to proceed with the analysis and print the values and positions of all the generated load cases.

PRINT MAXFORCE ENVELOP LIST 3 41 42

A maximum force envelope consisting of the highest forces for each degree of freedom on the listed members will be written into the output file.

FINISH

This command terminates the STAAD run.

**EX. US-13 Section Displacements for a Frame**

Calculation of displacements at intermediate points of members of a plane frame is demonstrated in this example.
This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-13 Section Displacements for a Frame.STD when you install the program.

![Figure 467: Example Problem No. 13](image)

Where:

- \( L_1 = 15 \text{ ft} \)
- \( L_2 = 20 \text{ ft} \)
- \( P = 5.0 \text{ k} \)
- \( w = 3.0 \text{ k/ft} \)

The dashed line represents the deflected shape of the structure. The shape is generated on the basis of displacements at the ends plus several intermediate points of the members.

Actual input is shown in bold lettering followed by explanation.

```
STAAD PLANE TEST FOR SECTION DISPLACEMENT
```

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

```
UNIT KIP FEET
```

Defines the input units for the data that follows.

```
JOINT COORDINATES
1 0. 0. ; 2 0. 15. ; 3 20. 15. ; 4 20. 0.
```

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.
Defines the members by the joints to which they are connected.

```
MEMBER PROPERTY AMERICAN
  1 3  TABLE  ST  W8X18
  2  TABLE  ST  W12X26
```

Properties for all members are assigned from the American AISC steel table. The word ST stands for standard single section.

```
UNIT INCHES
DEFINE MATERIAL START
  ISOTROPIC STEEL
  E 29000.0
  POISSON 0.3
  DENSITY 283e-006
  ALPHA 6e-006
  DAMP 0.03
  TYPE STEEL
  STRENGTH FY 36 FU 58 RY 1.5 RT 1.2
END DEFINE MATERIAL
MATERIAL STEEL ALL
```

The input units are changed from FT to INCH. The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
SUPPORT
  1 FIXED ; 4 PINNED
```

A fixed support is specified at Joint 1 and a pinned support at Joint 4.

```
UNIT FT
LOADING 1 DEAD + LIVE + WIND
```

Load case 1 is initiated followed by an optional title.

```
JOINT LOAD
  2 FX 5.
```

Load 1 contains a joint load of 5 kips at node 2. FX indicates that the load is a force in the global X direction.

```
MEMBER LOAD
  2 UNI GY -3.0
```

Load 1 contains a member load also. GY indicates that the load is in the global Y direction. The word UNI stands for uniformly distributed load.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis.

```
PRINT MEMBER FORCES
```

The above PRINT command is self-explanatory.

```
* FOLLOWING PRINT COMMAND WILL PRINT
* DISPLACEMENTS OF THE MEMBERS
* CONSIDERING EVERY TWELFTH INTERMEDIATE
* POINT (THAT IS TOTAL OF 13 POINTS). THESE
* DISPLACEMENTS ARE MEASURED IN GLOBAL X
* Y Z COORDINATE SYSTEM AND THE VALUES
* ARE FROM ORIGINAL COORDINATES (UNDEФLECTED
* POSITION) OF CORRESPONDING TWELFTH
```
The location of maximum intermediate displacement is determined. This value is measured from above location to the straight line joining start and end joints of the deflected member.

PRINT SECTION DISPLACEMENT

Above PRINT command is explained in the comment lines above.

FINISH

This command terminates the STAAD run.

EX. US-14 P-Delta Analysis of a Frame Under Seismic Loads

A space frame is analyzed for seismic loads. The seismic loads are generated using the procedures of the building code. A P-Delta analysis is performed to obtain the secondary effects of the lateral and vertical loads acting simultaneously.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-14 P-Delta Analysis of a Frame Under Seismic Loads.STD when you install the program.
Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame.

UNIT FEET KIP

Defines the input units for the data that follows.

J O I N T  C O O R D I N A T E S
1 0 0 0 4 3 0 0 0
REPEAT 3 0 0 1 0
REPEAT ALL 3 0 1 0 0

The X, Y and Z coordinates of the joints are specified here. First, coordinates of joints 1 through 4 are generated by taking advantage of the fact that they are equally spaced. Then, this pattern is REPEATED 3 times with a Z increment of 3.5 m for each repetition to generate joints 5 to 16. The REPEAT ALL command will then repeat 3 times, the pattern of joints 1 to 16 to generate joints 17 to 64.
**Application Examples**

**EX. American Design Examples**

```
110 29 30 112
REPEAT ALL 2 12 16
* beams in z direction
201 17 21 204
205 21 25 208
209 25 29 212
REPEAT ALL 2 12 16
* columns
301 1 17 348
```

Defines the members by the joints to which they are connected. Following the specification of incidences for members 101 to 112, the REPEAT ALL command is used to repeat the pattern and generate incidences for members 113 through 136. A similar logic is used in specification of incidences of members 201 through 212 and generation of incidences for members 213 to 236. Finally, members incidences of columns 301 to 348 are specified.

```
UNIT INCH
MEMBER PROPERTIES AMERICAN
101 TO 136 201 TO 236 PRIS YD 15 ZD 15
301 TO 348 TA ST W18X35
```

The beam members have prismatic member property specification (YD & ZD) while the columns (members 301 to 348) have their properties called from the built-in American (AISC) steel table.

```
DEFINE MATERIAL START

END DEFINE MATERIAL
CONSTANT
MATERIAL STEEL MEMB 301 TO 348
MATERIAL CONCRETE MEMB 101 TO 136 201 TO 236
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

**Tip:** You may see these values with the help of the command PRINT MATERIAL PROPERTIES following the preceding commands.

```
SUPPORT
1 TO 16 FIXED
```
Indicates the joints where the supports are located as well as the type of support restraints.

There are two stages in a static seismic load. The first stage is to define the code-specified load parameters along with the vertical loads (weights) from which the base shear will be calculated. The vertical loads may be specified in the form of selfweight, joint weights and/or member weights. Member weights are not shown in this example. It is important to note that these vertical loads are used purely in the determination of the horizontal base shear only. In other words, the structure is not analyzed for these vertical loads.

LOAD 1
- IBC LOAD X 0.75
- SELFWEIGHT Y -1.0
- JOINT LOADS
  - 17 TO 48 FY -2.5
  - 49 TO 64 FY -1.25

This is the second stage in which the static seismic load is applied with the help of a load case number, corresponding direction (X in the above case) and a factor by which the generated horizontal loads should be multiplied. Along with the seismic lateral load, deadweight is also added to the same load case. Since we will be doing second-order (PDELTA) analysis, it is important that we include horizontal and vertical loads in the same load case.

LOAD 2
- IBC LOAD Z 0.75
- SELFWEIGHT Y -1.0
- JOINT LOADS
  - 17 TO 48 FY -2.5
  - 49 TO 64 FY -1.25

In load case 2, the static seismic load is being applied in the Z direction. Vertical loads are part of this case, also.

**PDELTA ANALYSIS PRINT LOAD DATA**

We are requesting a second-order analysis by specifying the command **PDELTA ANALYSIS PRINT LOAD DATA** is used to obtain a report of all the applied and generated loadings.

- PRINT SUPPORT REACTIONS
- FINISH

The above commands are self-explanatory.

EX. US-15 Wind and Floor Load Generation on a Space Frame

A space frame is analyzed for loads generated using the built-in wind and floor load generation facilities.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-15 Wind and Floor Load Generation on a Space Frame.STD when you install the program.

Figure 469: Example Problem No. 15

STAAD SPACE - WIND AND FLOOR LOAD GENERATION

This is a space frame analysis problem. Every STAAD input has to start with the command STAAD. The SPACE specification is used to denote a space (3D) frame.

UNIT FEET KIP

The UNIT specification is used to specify the length and/or force units to be used.

JOINT COORDINATES
1 0 0 0
2 10 0 0
3 21 0 0
The JOINT COORDINATE specification is used to specify the X, Y, and Z coordinates of the joints. Note that the REPEAT ALL command has been used to generate joints for the two upper stories each with a Y increment of 12 ft.

MEMBER INCIDENCES

The MEMBER INCIDENCE specification is used for specifying member connectivities.

UNIT INCH
MEMBER PROPERTIES AMERICAN
  1 TO 16 TA ST W21X50
  17 TO 26 TA ST W18X35
  27 TO 36 TA ST W14X90

Properties for all members are specified from the built-in American (AISC) steel table. Three different sections have been used.

DEFINE MATERIAL START
  ISOTROPIC STEEL
  E 29000
  POISSON 0.3
  DENSITY 283e-006
  ALPHA 6e-006
  DAMP 0.03
  TYPE STEEL
  STRENGTH FY 36 FU 58 RY 1.5 RT 1.2
END DEFINE MATERIAL
  CONSTANT
  MATERIAL STEEL ALL

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

SUPPORT
  1 TO 8 FIXED BUT MX MZ

The supports of the structure are defined through the SUPPORT specification. Here all the supports are FIXED with releases specified in the MX (rotation about global X-axis) and MZ (rotation about global Z-axis) directions.
When a structure has to be analyzed for wind loading, the engineer is confronted with the task of first converting an abstract quantity like wind velocity or wind pressure into concentrated loads at joints, distributed loads on members, or pressure loads on plates. The large number of calculations involved in this conversion can be avoided by making use of STAAD’s wind load generation utility. This utility takes wind pressure at various heights as the input, and converts them to values that can then be used as concentrated forces known as joint loads in specific load cases. The input specification is done in two stages. The first stage is initiated above through the \textit{DEFINE WIND LOAD} command. The basic parameters of the WIND loading are specified here. All values need to be provided in the current UNIT system. Each wind category is identified with a \textit{TYPE} number (an identification mark) which is used later to specify load cases.

In this example, two different wind intensities (0.1 Kips/sq. ft and 0.15 Kips/sq. ft) are specified for two different height zones (0 to 12 ft. and 12 to 24 ft.). The \textit{EXPOSURE} specification is used to mitigate or magnify the effect at specific nodes due to special considerations like openings in the structure. In this case, two different exposure factors are specified. The first \textit{EXPOSURE} specification specifies the exposure factor as 0.9 for all joints within the height range (defined as global Y-range) of 11 ft. - 13 ft. The second \textit{EXPOSURE} specification specifies the exposure factor as 0.85 for joints 17, 20 and 22. In the \textit{EXPOSURE} factor specification, the joints may be specified directly or through a vertical range specification.

\textbf{LOAD 1 WIND LOAD IN X-DIRECTION}  
\textit{WIND LOAD X 1.2 TYPE 1}

This is the second stage of input specification for the wind load generation. The term \textit{WIND LOAD} and the direction term that follows are used to specify the wind loading in a particular lateral direction. In this case, \textit{WIND} loading \textit{TYPE 1}, defined previously, is being applied in the global X-direction with a positive multiplication factor of 1.2.

\textbf{LOAD 2 FLOOR LOAD @ Y = 12 FT AND 24 FT}  
\textit{FLOOR LOAD}  
\textit{YRANGE 11.9 12.1 FLOAD -0.45 XRANGE 0.0 10.0 ZRANGE 0.0 20.0}  
\textit{YRANGE 11.9 12.1 FLOAD -0.25 XRANGE 10.0 21.0 ZRANGE 0.0 20.0}  
\textit{YRANGE 23.9 24.1 FLOAD -0.25}

In load case 2 in this problem, a floor load generation is performed. In a floor load generation, a pressure load (force per unit area) is converted by the program into specific points forces and distributed forces on the members located in that region. The \textit{YRANGE}, \textit{XRANGE}, and \textit{ZRANGE} specifications are used to define the area of the structure on which the pressure is acting. The \textit{FLOAD} specification is used to specify the value of that pressure. All values need to be provided in the current UNIT system. For example, in the first line in the above \textit{FLOOR LOAD} specification, the region is defined as being located within the bounds \textit{YRANGE} of 11.9-12.1 ft, \textit{XRANGE} of 0.0-10.0 ft and \textit{ZRANGE} of 0.0-20.0 ft. The \textit{-0.45} signifies that the pressure is 0.45 Kip/sq. ft in the negative global Y direction.

The program will identify the members lying within the specified region and derive member loads on these members based on two-way load distribution.

\textbf{PERFORM ANALYSIS PRINT LOAD DATA}

We can view the values and position of the generated loads with the help of the \textit{PRINT LOAD DATA} command used above along with the \textit{PERFORM ANALYSIS} command.

\textbf{PRINT SUPPORT REACTION}  
\textbf{FINISH}

Above commands are self-explanatory.

SUPPORT REACTIONS -UNIT KIP FEET  STRUCTURE TYPE = SPACE
EX. US-16 Time History Analysis for Forcing Function and Ground Motion

Dynamic Analysis (Time History) is performed for a 3 span beam with concentrated and distributed masses. The structure is subjected to “forcing function” and “ground motion” loading. The maxima of joint displacements, member end forces and support reactions are determined.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-16 Time History Analysis for Forcing Function and Ground Motion.STD when you install the program.
Where:

\[ L_1 = 3.5 \text{ ft} \]

**STAAD PLANE EXAMPLE FOR TIME HISTORY ANALYSIS**

Every input file has to start with the word STAAD. The term PLANE signifies that the structure is a plane frame.

**UNITS FEET KIP**

Specifies the units to be used.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0.0 0.0 0.0</td>
</tr>
<tr>
<td>2 0.0 3.5 0.0</td>
</tr>
<tr>
<td>3 0.0 7.0 0.0</td>
</tr>
<tr>
<td>4 0.0 10.5 0.0</td>
</tr>
</tbody>
</table>

Joint number followed by the X, Y and Z coordinates are specified above.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 2 3</td>
</tr>
</tbody>
</table>
Incidences of members 1 to 3 are specified above.

```
UNIT INCH
MEMBER PROPERTIES
1 2 3 PRIS AX 3.0 IZ 240.0
```

All the members have PRISMATIC property specification. Since this is a plane frame, Area of cross section (AX) and Moment of Inertia (IZ) about the Z axis are adequate for the analysis.

```
SUPPORTS
1 4 PINNED
```

Pinned supports are located at nodes 1 and 4.

```
DEFINE MATERIAL
ISOTROPIC CONCRETE
E 14000
POISSON 0.17
DENSITY 8.7e-005
ALPHA 5e-006
G 1346.15
TYPE CONCRETE
STRENGTH FCU 4
END DEFINE MATERIAL
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
DEFINE TIME HISTORY
TYPE 1 FORCE
0.0 -0.0001 0.5 0.2244 1.5 0.2244 2.0 0.6731 2.5 -0.6731
TYPE 2 ACCELERATION
0.0 0.001 0.5 -7.721 1.0 -38.61 1.5 -38.61 2.0 -115.82 2.5 115.82
ARRIVAL TIMES
0.0
DAMPING 0.075
```

There are two stages in the command specification required for a time history analysis. The first stage is defined above. First the characteristics of the time varying load are provided. The loading type may be a forcing function (vibrating machinery) or ground motion (earthquake). The former is input in the form of time-force pairs while the latter is in the form of time-acceleration pairs. Following this data, all possible arrival times for these loads on the structure as well as the modal damping ratio are specified. In this example, the damping ratio is the same (7.5%) for all modes.

```
UNIT FEET
LOAD 1 STATIC LOAD
MEMBER LOAD
1 2 3 UNI GX 0.5
```

Load case 1 above is a static load. A uniformly distributed force of 0.5 kip/ft acts along the global X direction on all 3 members.

```
LOAD 2 TIME HISTORY LOAD
SELFWEIGHT X 1.0
SELFWEIGHT Y 1.0
JOIN LOAD
2 3 FX 2.5
TIME LOAD
```
This is the second stage in the command specification for time history analysis. This involves the application of
the time varying load on the structure. The masses that constitute the mass matrix of the structure are specified
through the selfweight and joint load commands. The program will extract the lumped masses from these
weights. Following that, both the TIME LOAD and GROUND MOTION are applied simultaneously.

**Note:** This example is only for illustration purposes and that it may be unlikely that a TIME LOAD and GROUND
MOTION both act on the structure at the same time.

The Time load command is used to apply the Type 1 force, acting in the global X direction, at arrival time number
1, at nodes 2 and 3. The Ground motion, namely, the Type 2 time history loading, is also in the global X direction
at arrival time 1.

The above command initiates the analysis process.

During the analysis, the program calculates joint displacements for every time step. The absolute maximum
value of the displacement for every joint is then extracted from this joint displacement history. So, the value
printed using the above command is the absolute maximum value for each of the six degrees of freedom at each
node.

The member forces and support reactions too are calculated for every time step. For each degree of freedom, the
maximum value of the member force and support reaction is extracted from these histories and reported in the
output file using the above command.

*************** END OF LATEST ANALYSIS RESULT ***************
### EX. US-17 User-Provided Tables

The usage of user-provided steel tables is illustrated in this example for the analysis and design of a plane frame. User-provided tables allow you to specify property data for sections not found in the built-in steel section tables.

This problem is installed with the program by default to `C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-17 User-Provided Tables.STD` when you install the program.
Figure 471: Example Problem No. 17

Where:

\[ L_1 = 15 \text{ ft}, \quad L_2 = 20 \text{ ft} \]
\[ P = 5.0 \text{ k} \]
\[ w = 3.0 \text{ k/ft} \]

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE EXAMPLE FOR USER TABLE**

Every input file has to start with the command STAAD. The PLANE command is used to designate the structure as a plane frame.

**UNIT FT KIP**
The UNIT command sets the length and force units to be used.

**JOINT COORDINATES**

```
1 0. 0.; 2 30 0; 3 0 20 0 6 30 20 0
7 0 35; 8 30 35; 9 7.5 35; 10 22.5 35.
11 15 35; 12 5.38; 13 25 38; 14 10 41; 15 20 41
16 15 44
```

The above set of data is used to provide joint coordinates for the various joints of the structure. The Cartesian system is being used here. The data consists of the joint number followed by global X and Y coordinates. Note that for a space frame, the Z coordinate(s) need to be provided also.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

**MEMBER INCIDENCES**

```
1 1 3; 2 3 7; 3 2 6; 4 6 8; 5 3 4
6 4 5; 7 5 6; 8 7 12; 9 12 14
10 14 16; 11 15 16; 12 13 15; 13 8 13
14 9 12; 15 9 14; 16 11 14; 17 11 15
18 10 15; 19 10 13; 20 7 9
21 9 11; 22 10 11; 23 8 10
```

The above data set contains the member incidence information or the joint connectivity data for each member. This completes the geometry of the structure.

**START USER TABLE**

This command is utilized to set up a user-provided steel table. All user-provided steel tables must start with this command.

**TABLE 1**

Each table needs an unique numerical identification. The above command starts setting up Table no. 1. Up to twenty tables may be specified per run.

**UNIT INCH**

**WIDE FLANGE**

This command is used to specify the section-type as WIDE FLANGE in this table. Note that several section-types such as WIDE FLANGE, CHANNEL, ANGLE, TEE etc. are available for specification (see section 5.19 of the Technical Reference Manual on page 2446).

```
WFL14X30
  8.85 13.84 .27 6.73 .385 291. 19.6 .38 4.0 4.1
WFL21X62
  18.3 20.99 .4 8.24 .615 1330 57.5 1.83 0.84 7.0
WFL14X109
```

The above data set is used to specify the properties of three wide flange sections. The data for each section consists of two parts. In the first line, the section-name is provided. You are allowed to provide any section name within twelve characters. The second line contains the section properties required for the particular section-type. Each section-type requires a certain number of data (area of cross-section, depth, moment of inertias etc.) provided in a certain order. For example, in this case, for wide flanges, ten different properties are required.

**TABLE 2**

**ANGLES**

```
LANG25255
  2.5 2.5 .3125 .489 0 0
LANG40404
  4 4 .25 .795 0 0
```
The above command and data lines set up another user provided table consisting of angle sections.

This command signifies the end of the user provided table data set. All user provided table related input must be terminated with this command.

In the above command lines, the member properties are being assigned from the user provided tables created earlier. The word UPT signifies that the properties are from the user-provided table. This is followed by the table number and then the section name as specified in the use- provided table. The numbers 1 or 2 following the word UPT indicate the table from which section names are fetched.

The above command is used to designate members 14 to 23 as truss members.

The MEMBER RELEASE command is used to release the MZ moment at the start joint of member no. 5.

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

The length unit is reset to feet using this command.

The length unit is reset to feet using this command.

The above command set is used to designate supports. Here, joint 1 is designated as a fixed support and joint 2 is designated as a pinned support.
MEMB LOAD
  8 TO 13 UNI Y -0.9 ; 6 UNI GY -1.2

The above command set is used to specify the loadings on the structure. In this case, dead and live loads are provided through load case 1. It consists of selfweight, concentrated loads at joints 4, 5 and 11, and distributed loads on some members.

PERFORM ANALYSIS

This command instructs the program to execute the analysis at this point.

PARAMETER
  
  CODE AISC UNIFIED
  BEAM 1.0 ALL
  NSF 0.85 ALL
  KY 1.2 MEMB 3 4

The above commands are used to specify parameters for steel design.

SELECT MEMBER 3 6 9 19

This command will perform selection of members per the AISC ASD steel design code. For each member, the member selection will be performed from the table that was originally used for the specification of the member property. In this case, the selection will be from the respective user tables from which the properties were initially assigned. It may be noted that properties may be provided (and selection may be performed) from built-in steel tables and user provided tables in the same data file.

FINISH

This command terminates a STAAD run.

STAAD.PRO MEMBER SELECTION - AISC 360-16 LRFD (V1.1)

*************************************************************************
ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
=========================================
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.
AISC Spec.        STAAD.Pro        Description
--------------------        ------------------------
X                     Z               Axis typically parallel to the sections principal
major axis.
Y                     Y               Axis typically parallel to the sections principal
minor axis.
Z                     X               Longitudinal axis perpendicular to the cross section.

SECTION FORCES AXIS MAPPING: -
AISC Spec.        STAAD.Pro        Description
--------------------        ------------------------
Pz                     FX              Axial force.
Vy                     FY              Shear force along minor axis.
Vx                     FZ              Shear force along major axis.
Tz                     MX              Torsional moment.
My                     MY              Bending moment about minor axis.
Mx                     MZ              Bending moment about major axis.

*** DESIGN MESSAGES ***:
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis. E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** ABBREVIATIONS ***:

F-T-B = Flexural-Torsional Buckling
L-T-B = Lateral-Torsional Buckling
F-L-B = Flange Local Buckling
W-L-B = Web Local Buckling
L-L-B = Leg Local Buckling
C-F-Y = Compression Flange Yielding
T-F-Y = Tension Flange Yielding

Where:

$L = 1 \text{ ft}$

Fixed Supports at Joints 1, 2, 3, 4, 5, 9, 13

Load intensity = 1 psi (pound/in$^2$) in negative global Y direction

Actual input is shown in bold lettering followed by explanation.

**STAAD SPACE SAMPLE CALCULATION FOR**

* ELEMENT STRESSES

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame (3-D structure).

**UNIT KIP FEET**

Defines the input units for the data that follows.

**JOINT COORDINATES**

1 0 0 4 3 0 0 0

REPEAT 3 0 0 1

Joint number followed by X, Y and Z coordinates are provided above. The REPEAT command is used to generate coordinates of joints 5 to 16 based on the pattern of joints 1 to 4.

**ELEMENT INCIDENCE**

1 1 5 6 2 TO 3

REPEAT 2 3 4
Element connectivities of elements 1 to 3 are defined first, based on which, the connectivities of elements 4 to 9 are generated.

```
UNIT INCH
ELEMENT PROPERTIES
1 TO 9 THICK 1.0
```

Elements 1 to 9 have a thickness of 1.0 in.

```
DEFINE MATERIAL START
ISOTROPIC CONCRETE
E 3150
POISSON 0.17
DENSITY 8.7e-005
ALPHA 5e-006
DAMP 0.05
G 1346.15
TYPE CONCRETE
STRENGTH FCU 4
END DEFINE MATERIAL
CONSTANTS
MATERIAL CONCRETE ALL
```

The `DEFINE MATERIAL` command is used to specify material properties and the `CONSTANT` is used to assign the material to all members.

```
SUPPORT
1 TO 4 5 9 13 FIXED
```

Fixed support conditions exist at the above mentioned joints.

```
UNIT POUND
LOAD 1
ELEMENT LOAD
1 TO 9 PRESSURE -1.0
```

A uniform pressure of 1 pound/sq. in is applied on all the elements. In the absence of an explicit direction specification, the load is assumed to act along the local Z axis. The negative value indicates that the load acts opposite to the positive direction of the local Z.

```
PERFORM ANALYSIS
```

The above command instructs the program to proceed with the analysis.

```
PRINT SUPPORT REACTION
```

The above command is self-explanatory.

```
PRINT ELEMENT STRESSES LIST 4
```

Element stresses at the centroid of the element are printed using the above command. The output includes membrane stresses, shear stresses, bending moments per unit width and principal stresses.

```
FINISH
```

The STAAD run is terminated.

**Calculation of principal stresses for element 4**

Calculations are presented for the top surface only.

\[ SX = 0.0 \text{ lb/in}^2 \]
SY = 0.0 lb/in²
SXY = 0.0 lb/in²
MX = 16.90 lb in/in
MY = 85.81 lb in/in
MXY = 36.43 lb in/in
S = 1/6t² = 1/6 · 1² = 0.1667 in³ (Section Modulus)

σₓ = SX + MX/S = 0.0 + 16.90/0.1667 = 101.38 psi
σᵧ = SY + MY/S = 0.0 + 85.81/0.1667 = 514.75 psi
τₓᵧ = SXY + MXY/S = 0.0 + 36.43/0.1667 = 218.54 psi

T_max = \sqrt{\frac{(σₓ - σᵧ)²}{4} + \frac{τₓᵧ²}{4}} = \sqrt{\frac{(101.38 - 514.75)²}{4} + 218.54²} = 300.80 psi

S_max = (σₓ + σᵧ)/2 + T_max = (101.38 + 514.75)/2 + 300.80 = 608.87 psi
S_min = (σₓ + σᵧ)/2 - T_max = (101.38 + 514.75)/2 - 300.80 = 7.27 psi

Angle = \frac{1}{2} \tan^{-1}\left(\frac{2τₓᵧ}{σₓ - σᵧ}\right) = \frac{1}{2} \tan^{-1}\left(\frac{2(218.54)}{101.38 - 514.75}\right) = -23.30°

VON = 0.707\sqrt{(S_{max} - S_{min})² + S_{max}² + S_{min}²} = 0.707\sqrt{(608.87 - 7.27)² + 608.87² + 7.27²} = 605.18 psi

*********** END OF THE STAAD.Pro RUN ***********
EX. US-19 Inclined Supports

This example demonstrates the usage of inclined supports. The word INCLINED refers to the fact that the restraints at a joint where such a support is specified are along a user-specified axis system instead of along the default directions of the global axis system. STAAD.Pro offers a few different methods for assigning inclined supports, and we examine those in this example.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-19 Inclined Supports.STD when you install the program.

Figure 473: Example Problem No. 19

Actual input is shown in bold lettering followed by explanation.

```
STAAD SPACE
INPUT WIDTH 79

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y, and Z coordinates.

UNIT METER KN

Defines the input units for the data that follows.

JOINT COORDINATES
1 0 5 0; 2 10 5 10; 3 20 5 20; 4 30 5 30; 5 5 0 5; 6 25 0 25;

Joint number followed by X, Y and Z coordinates are provided above.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCES
1 1 2; 2 2 3; 3 3 4; 4 5 2; 5 6 3;

Defines the members by the joints to which they are connected.

UNIT MMS KN
MEMBER PROPERTY AMERICAN
4 5 PRIS YD 800
1 TO 3 PRIS YD 750 ZD 500
```
Properties for all members of the model are provided using the PRISMATIC option (abbreviated to PRIS here). YD and ZD stand for depth and width. If ZD is not provided, a circular shape with diameter = YD is assumed for that cross section. All properties required for the analysis, such as, Area, Moments of Inertia, etc. are calculated automatically from these dimensions unless these are explicitly defined. The values are provided in MMS unit.

```

STRENGTH FCU 0.0275
END DEFINE MATERIAL
```

Material constants like E (modulus of elasticity) and Poisson's ratio are specified following the command CONSTANTS.

```
UNIT METER KN
SUPPORTS
5 INCLINED REF 10 5 10 FIXED BUT MX MY MZ KFX 30000
6 INCLINED REFJT 3 FIXED BUT MX MY MZ KFX 30000
1 PINNED
4 INCLINED 1 0 1 FIXED BUT FX MX MY MZ
```

We assign supports (restraints) at 4 nodes - 5, 6, 1 and 4. For 3 of those, namely, 5, 6 and 4, the node number is followed by the keyword INCLINED, signifying that an INCLINED support is defined there. For the remaining one - node 1 - that keyword is missing. Hence, the support at node 1 is a global direction support.

The most important aspect of inclined supports is their axis system. Each node where an inclined support is defined has its own distinct local X, local Y and local Z axes. In order to define the axis system, we first have to define a datum point. The support node and the datum point together help define the axis system.

Three different methods are shown in the above 3 instances for defining the datum point.

- At node 5, notice the keyword REF followed by the numbers (10,5,10). This means that the datum point associated with node 5 is one which has the global coordinates of (10m, 5m, 10m). Coincidentally, this happens to be node 2.
- At node 6, the keyword REFJT is used followed by the number 3. This means that the datum point for support node 6 is the joint number 3 of the model. The coordinates of the datum point are hence those of node 3, namely, (20m, 5m and 20m).
- At node 4, the word INCLINED is merely followed by 3 numbers (1,0,1). In the absence of the words REF and REFJT, the program sets the datum point to be the following. It takes the coordinates of node 4, which are (30m,5m,30m) and adds to them, the 3 numbers which comes after the word INCLINED. Thus, the datum point becomes (31m, 5m and 31m).

Once the datum point is established, the local axis system is defined as follows. Local X is a straight line (vector) pointing from the support node towards the datum point. Local Z is the vector obtained by the cross product of local X and the global Y axis (unless the SET Z UP command is used in which case one would use global Z instead of global Y and that would yield local Y). Local Y is the vector resulting from the cross product of local Z and local X. The right hand rule must be used when performing these cross products.
Notice the unique nature of these datum points. The one for node 5 tells us that a line connecting nodes 5 to 2 is the local X axis, and is hence along the axis of member 4. By defining a KFX spring at that one, we are saying that the lower end of member 4 can move along its axis like the piston of a car engine. Think of a pile bored into rock with a certain amount of freedom to expand and contract axially.

The same is true for the support at the bottom of member 5. The local X axis of that support is along the axis of member 5. That also happens to be the case for the supported end of member 3. The line going from node 4 to the datum point (31,5,31) happens to be coincident with the axis of the member, or the traffic direction. The expression FIXED BUT FX MX MY MZ for that support indicates that it is free to translate along local X, suggesting that it is an expansion joint - free to expand or contract along the axis of member 3.

Since MX, MY, and MZ are all released at these supports, no moment will be resisted by these supports.

Three load cases followed by the instruction for the type of analysis are specified. The PRINT STATICS CHECK option will instruct the program to produce a report consisting of total applied load versus total reactions from the supports for each primary load case.

By default, support reactions are printed in the global axis directions. The above command is an instruction for such a report.

Just earlier, we saw how to obtain support reactions in the global axis system. What if we need them in the inclined axis system? The “SET INCLINED REACTION” is a switch for that purpose. It tells the program that reactions should be reported in the inclined axis system instead of the global axis system. This has to be followed by the PRINT SUPPORT REACTIONS command.

Member forces are reported in the local axis system of the members. Joint displacements at all joints are reported in the global axis system. Following this, the STAAD run is terminated.

### EX. US-20 Generating a Structure in Cylindrical Coordinates

This example generates the geometry of a cylindrical tank structure using the cylindrical coordinate system. The tank lies on its side in this example.
This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-20
Generating a Structure in Cylindrical Coordinates.STD when you install the program.

In this example, a cylindrical tank is modeled using finite elements. The radial direction is in the XY plane and longitudinal direction is along the Z-axis. Hence, the coordinates in the XY plane are generated using the cylindrical coordinate system.

STAAD SPACE
UNIT KIP FEET

The type of structure (space frame) and length and force units for data to follow are specified.

JOINT COORD CYLINDRICAL

The above command instructs the program that the coordinate data that follows is in the cylindrical coordinate system (r,theta,z).

1 10 0 0 8 10 315 0

Joint 1 has an 'r' of 10 feet, theta of 0 degrees and Z of 0 ft. Joint 8 has an 'r' of 10 feet, theta of 315 degrees and Z of 0 ft. The 315 degrees angle is measured counter-clockwise from the +ve direction of the X-axis. Joints 2 to 7 are generated by equal increments of the coordinate values between joints 1 and 8.

REPEAT 2 0 0 8.5

The REPEAT command is used to generate joints 9 through 24 by repeating twice, the pattern of joints 1 to 8 at Z-increments of 8.5 ft for each REPEAT.

PRINT JOINT COORD
The above command is used to produce a report consisting of the coordinates of all the joints in the Cartesian coordinate system. Note that even though the input data was in the cylindrical coordinate system, the output is in the Cartesian coordinate system.

```
ELEMENT INCIDENCES
  1 1 2 10 9 TO 7 1 1
  8 8 1 9 16
REPEAT ALL 1 8 8
```

The above 4 lines identify the element incidences of all 16 elements. Incidences of element 1 is defined as 1 2 10 9. Incidences of element 2 is generated by incrementing the joint numbers of element 1 by 1, incidences of element 3 is generated by incrementing the incidences of element 2 by 1 and so on up to element 7. Incidences of element 8 has been defined above as 8 1 9 16. The REPEAT ALL command states that the pattern of all the elements defined by the previous 2 lines, namely elements 1 to 8, must be repeated once with an element number increment of 8 and a joint number increment of 8 to generate elements 9 through 16.

```
PRINT ELEMENT INFO
```

The above command is self-explanatory.

```
FINISH
```

### EX. US-21 Analysis of a Structure with Tension-Only Members

This example illustrates the modeling of tension-only members using the **MEMBER TENSION** command.

This problem is installed with the program by default to

```
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-21
```

Analysis of a Structure with Tension-Only Members.STD when you install the program.
It is important to note that the analysis can be done for only 1 load case at a time. This is because, the set of “active” members (and hence the stiffness matrix) is load case dependent.

![Figure 475: Example Problem No. 21](image)

where:

- $L = 15\text{ ft}$, $H = 10\text{ ft}$
- Load case 1: $P_1 = 10\text{ kips}$ & $P_2 = 15\text{ kips}$
- Load case 2: $P_3 = -10\text{ kips}$ & $P_4 = -15\text{ kips}$

**STAAD PLANE EXAMPLE FOR TENSION-ONLY MEMBERS**

The input data is initiated with the word STAAD. This structure is a PLANE frame.

**UNIT FEET KIP**

Units for the commands to follow are defined above.

**JOINT COORDINATES**

1 0 0 ; 2 0 10 ; 3 0 20 ; 4 15 20 ; 5 15 10 ; 6 15 0
Joint coordinates of joints 1 to 6 are defined above.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 5</td>
</tr>
<tr>
<td>6 1 5 ; 7 2 6 ; 8 2 4 ; 9 3 5 ; 10 2 5</td>
</tr>
</tbody>
</table>

Incidences of members 1 to 10 are defined.

<table>
<thead>
<tr>
<th>MEMBER TENSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 TO 9</td>
</tr>
</tbody>
</table>

Members 6 to 9 are defined as tension-only members using the MEMBER TENSION command. Hence for each load case, if during the analysis, any of the members 6 to 9 is found to be carrying a compressive force, it is disabled from the structure and the analysis is carried out again with the modified structure.

<table>
<thead>
<tr>
<th>MEMBER PROPERTY AMERICAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 10 TA ST W12X26</td>
</tr>
</tbody>
</table>

All members have been assigned a WIDE FLANGE section from the built in American table.

<table>
<thead>
<tr>
<th>UNIT INCH</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINE MATERIAL START</td>
</tr>
<tr>
<td>ISOTROPIC STEEL</td>
</tr>
<tr>
<td>E 29000</td>
</tr>
<tr>
<td>POISSON 0.3</td>
</tr>
<tr>
<td>DENSITY 283e-006</td>
</tr>
<tr>
<td>ALPHA 6e-006</td>
</tr>
<tr>
<td>DAMP 0.03</td>
</tr>
<tr>
<td>TYPE STEEL</td>
</tr>
<tr>
<td>STRENGTH FY 36 FU 58 RY 1.5 RT 1.2</td>
</tr>
<tr>
<td>END DEFINE MATERIAL</td>
</tr>
<tr>
<td>CONSTANT</td>
</tr>
<tr>
<td>MATERIAL STEEL ALL</td>
</tr>
</tbody>
</table>

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members. The length units have been changed from feet to inch to facilitate the input of these values.

<table>
<thead>
<tr>
<th>SUPPORT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 6 PINNED</td>
</tr>
</tbody>
</table>

The supports are defined above.

<table>
<thead>
<tr>
<th>MEMBER TENSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 TO 9</td>
</tr>
</tbody>
</table>

One or more among the members 6 to 9 may have been inactivated in the analysis.

<table>
<thead>
<tr>
<th>LOAD 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>JOINT LOAD</td>
</tr>
<tr>
<td>2 FX 15</td>
</tr>
<tr>
<td>3 FX 10</td>
</tr>
</tbody>
</table>

Load 1 is defined above and consists of joint loads at joints 2 and 3.

<table>
<thead>
<tr>
<th>LOAD 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>JOINT LOAD</td>
</tr>
<tr>
<td>4 FX -10</td>
</tr>
<tr>
<td>5 FX -15</td>
</tr>
</tbody>
</table>
Load case 2 is described above.

```
LOAD 3
REPEAT LOAD
  1 1.0 2 1.0
```

Load case 3 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases already specified earlier. We would like the program to analyze the structure for loads from cases 1 and 2 acting simultaneously.

```
PRINT ANALYSIS RESULTS
FINI
```

The analysis results are printed and the run terminated.

**EX. US-22 Time History Analysis for Sinusoidal Loading**

A space frame structure is subjected to a sinusoidal (dynamic) loading. The commands necessary to describe the sine function are demonstrated in this example. Time History analysis is performed on this model.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-22 Time History Analysis for Sinusoidal Loading.STD when you install the program.
STAAD SPACE

*EXAMPLE FOR HARMONIC LOADING GENERATOR

Every STAAD input file has to begin with the word STAAD.

The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. The comment line which begins with an asterisk is an optional title to identify this project.

UNIT KIP FEET

The units for the data that follows are specified above.

JOINT COORDINATES

1 0 0 0 ; 2 15 0 0 ; 3 15 0 15 ; 4 0 0 15
5 0 20 0 ; 6 7.5 20 0 ; 7 15 20 0 ; 8 15 20 7.5
9 15 20 15 ; 10 7.5 20 15 ; 11 0 20 15
12 0 20 7.5

The joint number followed by the X, Y and Z coordinates are specified above.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCES

1 1 5 ; 2 2 7 ; 3 3 9 ; 4 4 11 ; 5 5 6 ; 6 6 7
7 7 8 ; 8 8 9 ; 9 9 10 ; 10 10 11 ; 11 11 12 ; 12 12 5
13 6 13 ; 14 13 10 ; 15 8 13 ; 16 13 12

The members are defined by the joints to which they are connected.

UNIT INCH
MEMBER PROPERTIES
1 TO 12 PRIS YD 12 ZD 12
Members 1 to 12 are defined as PRISmatic sections with width and depth values of 12 inches. The UNIT command is specified to change the units for input from FEET to INCHes.

<table>
<thead>
<tr>
<th>SUPPORTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 4 PINNED</td>
</tr>
</tbody>

END DEFINE MATERIAL
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
DEFINE TIME HISTORY
  TYPE 1 FORCE
  * FOLLOWING LINES FOR HARMONIC LOADING GENERATOR
  FUNCTION SINE
  AMPLITUDE 6.2831 FREQUENCY 60 CYCLES 100
  *
  ARRIVAL TIMES
  0.0
  DAMPING 0.075
```

There are two stages in the command specification required for a time-history analysis. The first stage is defined above. Here, the parameters of the sinusoidal loading are provided.

Each data set is individually identified by the number that follows the TYPE command. In this file, only one data set is defined, which is apparent from the fact that only one TYPE is defined.

The word FORCE that follows the TYPE 1 command signifies that this data set is for a forcing function. (If you want to specify an earthquake motion, an ACCELERATION may be specified.)

The command FUNCTION SINE indicates that instead of providing the data set as discrete TIME-FORCE pairs, a sinusoidal function, which describes the variation of force with time, is provided.

The parameters of the sine function, such as FREQUENCY, AMPLITUDE, and number of CYCLES of application are then defined. STAAD internally generates discrete TIME-FORCE pairs of data from the sine function in steps of time defined by the default value (see section 5.31.4 of the Technical Reference Manual (on page 2630) for more information). The arrival time value indicates the relative value of time at which the force begins to act upon the structure. The modal damping ratio for all the modes is set to 0.075.

```
LOAD 1 STATIC LOAD CASE
  MEMBER LOAD
  5 6 7 8 9 10 11 12 UNI GY -1.0
```

The above data describe a static load case.

```
LOAD 2 DYNAMIC LOAD CASE
  SELFWEIGHT X 1.0
```
This is the second stage of command specification for time history analysis. The two sets of data specified here are:

a. the weights for generation of the mass matrix
b. the application of the time varying loads on the structure.

The weights (from which the masses for the mass matrix are obtained) are specified in the form of selfweight and joint loads.

Following that, the sinusoidal force is applied using the TIME LOAD command. The forcing function described by the TYPE 1 load is applied on joints 8 and 12 and it starts to act starting at a time defined by the 1st arrival time number.

The above commands are self explanatory. The FINISH command terminates the STAAD run.

**EX. US-23 Spring Support Generation for a Slab on Grade**

This example illustrates the usage of commands necessary to automatically generate spring supports for a slab on grade. The slab is subjected to pressure loading and analysis of the structure is performed.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-23
Spring Support Generation for a Slab on Grade.STD when you install the program.
where:

\[
H = 129', h1 = 8' - 6'', h2 = 8', h3 = 6' \\
V = 40', v1 = 6' - 6'', v2 = 6', v3 = 7' - 10'', v4 = 4'
\]

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. The remainder of the words form a title to identify this project.

UNIT FEET KIP

The units for the data that follows are specified above.

JOINT COORDINATES
1 0.0 0.0 40.0  
2 0.0 0.0 36.0  
3 0.0 0.0 28.167  
4 0.0 0.0 20.333  
5 0.0 0.0 12.5  
6 0.0 0.0  6.5  
7 0.0 0.0  0.0  
REPEAT ALL 3 8.5 0.0 0.0  
REPEAT 3 8.0 0.0 0.0  
REPEAT 5 6.0 0.0 0.0  
REPEAT 3 8.0 0.0 0.0  
REPEAT 3 8.5 0.0 0.0  

For joints 1 through 7, the joint number followed by the X, Y, and Z coordinates are specified above. The coordinates of these joints is used as a basis for generating 21 more joints by incrementing the X coordinate of each of these seven joints by 8.5 feet, three times REPEAT commands are used to generate the remaining joints of the structure. The results of the generation may be visually verified using the STAAD graphical viewing facilities.

ELEMENT INCIDENCES
1 1 8 9 2 TO 6  
REPEAT 16 6 7
The incidences of element number 1 is defined and that data is used as a basis for generating the 2nd through the 6th element. The incidence pattern of the first six elements is then used to generate the incidences of 96 (= 16 x 6) more elements using the REPEAT command.

```
UNIT INCH
ELEMENT PROPERTIES
1 TO 102 TH 5.5
```

The thickness of elements 1 to 102 is specified as 5.5 inches following the command ELEMENT PROPERTIES.

```
DEFINE MATERIAL START
ISOTROPIC CONCRETE
E 2916.7
POISSON 0.12
DENSITY 8.68e-005
ALPHA 5e-006
DAMP 0.05
G 1346.15
TYPE CONCRETE
STRENGTH FCU 4
END DEFINE MATERIAL
CONSTANTS
MATERIAL CONCRETE ALL
UNIT FEET
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
SUPPORTS
1 TO 126 ELASTIC MAT DIRECTION Y SUB 10.0
```

The above command is used to instruct STAAD to generate supports with springs which are effective in the global Y direction. These springs are located at nodes 1 to 126. The subgrade modulus of the soil is specified as 10 kip/cu.ft. The program will determine the area under the influence of each joint and multiply the influence area by the subgrade reaction to arrive at the spring stiffness for the FY degree of freedom at the joint. See Section 5.27.3 in the STAAD Technical Reference Manual (on page 2517).

```
PRINT SUPP INFO
```

This command will enable us to obtain the details of the support conditions which were generated using the earlier commands.

```
LOAD 1 WEIGHT OF MAT & EARTH
ELEMENT LOAD
1 TO 102 PR GY -1.55
```

The above data describe a static load case. A pressure load of 1.55 kip/sq.ft acting in the negative global Y direction is applied on all the 102 elements.

```
LOAD 2 'COLUMN LOAD-DL+LL'
JOINT LOADS
1 2 FY -217.
8 9 FY -109.
5 FY -308.7
6 FY -617.4
22 23 FY -410.
29 30 FY -205.
26 FY -542.7
27 FY -1085.4
43 44 50 51 71 72 78 79 FY -307.5
47 54 82 FY -264.2
```
Load case 2 consists of several joint loads acting in the negative global Y direction.

<table>
<thead>

</tr>
</tbody>
</table>

A load combination case, identified with load case number 101, is specified above. It instructs STAAD to factor loads 1 and 2 by a value of 1.0 and then algebraically add the results.

**PERFORM ANALYSIS**

The analysis is initiated using the above command.

**LOAD LIST 101**
**PRINT JOINT DISPLACEMENTS LIST 33 56**
**PRINT ELEMENT STRESSES LIST 34 67**

Joint displacements for joints 33 and 56, and element stresses for elements 34 and 67, for load case 101, is obtained with the help of the above commands.

**FINISH**

The STAAD run is terminated.

EX. US-24 Analysis of a Concrete Block Using Solid Elements

This is an example of the analysis of a structure modeled using solid finite elements. This example also illustrates the method for applying an enforced displacement on the structure.
This problem is installed with the program by default to 
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-24 
Analysis of a Concrete Block Using Solid Elements.STD when you install the program.

STAAD SPACE 
*EXAMPLE PROBLEM USING SOLID ELEMENTS

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. The comment line which begins with an asterisk is an optional title to identify this project.

UNIT KNS MET

The units for the data that follows are specified above.

<table>
<thead>
<tr>

</tbody>
</table>

Figure 478: Example Problem No. 24
The joint number followed by the X, Y, and Z coordinates are specified above. The coordinates of some of those nodes are generated utilizing the fact that they are equally spaced between the extremities.

<table>

</tbody>
</table>

The incidences of solid elements are defined above. The word SOLID is used to signify that these are 8-node solid elements as opposed to 3-noded or 4-noded plate elements. Each line contains the data for generating 3 elements. For example, element number 1 is first defined by all of its 8 nodes. Then, increments of 1 to the joint number and 1 to the element number (the defaults) are used for generating incidences for elements 2 and 3. Similarly, incidences of elements 4, 7 and 10 are defined while those of 5, 6, 8, 9, 11 and 12 are generated.

END DEFINE MATERIAL
CONSTANTS
MATERIAL STEEL ALL
UNIT METERL

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

PRINT ELEMENT INFO SOLID LIST 1 TO 5

This command will enable us to obtain, in a tabular form, the details of the incidences and material property values of elements 1 to 5.

SUPPORTS
1 5 21 25 29 41 45 49 PINNED
9 ENFORCED

The above lines contain the data for supports for the model. The ENFORCED support condition is used to declare a point at which an enforced displacement load is applied later (see load case 3).

LOAD 1
SELF Y -1.0
JOINT LOAD
28 FY -1000.0

The above data describe a static load case. It consists of selfweight loading and a joint load, both in the negative global Y direction.

LOAD 2
JOINT LOADS
2 TO 4 22 TO 24 42 TO 44 FX 100.0

Load case 2 consists of several joint loads acting in the positive global X direction.

LOAD 3
SUPPORT DISPLACEMENT
9 FX 0.0011
Load case 3 consists of an enforced displacement along the global X direction at node 9. The displacement in the other enforced support degrees of freedom will default to zero.

</tbody>
</table>

In Load case 4, a pressure load of 500 pounds/sq.ft is applied on Face # 4 of solid elements 3, 6, 9 and 12. Face 4 is defined as shown in the following table:

<table>
<thead>
<tr>
<th>Face Number</th>
<th>Surface Joints</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 front</td>
<td>Jt 1, Jt 4, Jt 3, Jt 2</td>
</tr>
<tr>
<td>2 bottom</td>
<td>Jt 1, Jt 2, Jt 6, Jt 5</td>
</tr>
<tr>
<td>3 left</td>
<td>Jt 1, Jt 5, Jt 8, Jt 4</td>
</tr>
<tr>
<td>4 top</td>
<td>Jt 4, Jt 8, Jt 7, Jt 3</td>
</tr>
<tr>
<td>5 right</td>
<td>Jt 2, Jt 3, Jt 7, Jt 6</td>
</tr>
<tr>
<td>6 back</td>
<td>Jt 5, Jt 6, Jt 7, Jt 8</td>
</tr>
</tbody>
</table>

The above table, and other details of this type of loading can be found in section 5.32.3.2 of the STAAD.Pro Technical Reference manual (on page 2660).

<table>
<thead>
<tr>
<th>UNIT</th>
<th>KNS MMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOAD</td>
<td>5</td>
</tr>
<tr>
<td>REPEAT LOAD</td>
<td>1 1.0 2 1.0 3 1.0 4 1.0</td>
</tr>
</tbody>
</table>

Load case 5 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases already specified earlier. We want the program to analyze the structure for loads from cases 1 through 4 acting simultaneously. In other words, the above instruction is the same as the following:

```
LOAD 5
SELF Y -1.0
JOINT LOAD
28 FY -1000.0
2 TO 4 22 TO 24 42 TO 44 FX 100.0
SUPPORT DISPLACEMENT
9 FX .0011
ELEMENT LOAD SOLIDS
3 6 9 12 FACE 4 PRE GY -500.0
LOAD COMB 10
1 1.0 2 1.0
```

Load case 10 is a combination load case, which combines the effects of cases 1 & 2. While the syntax of this might look very similar to that of the REPEAT LOAD case shown in case 5, there is a fundamental difference. In a REPEAT LOAD case, the program computes the displacements by multiplying the inverted stiffness matrix by the
load vector built for the REPEAT LOAD case. But in solving load combination cases, the program merely calculates the end results (displacements, forces, reactions) by gathering up the corresponding values from the individual components of the combination case, factoring them, and then algebraically summing them up. This difference in approach is quite important in that non-linear problems such as PDELTA ANALYSIS, MEMBER TENSION, and MEMBER COMPRESSION situations, changes in support conditions etc. should be handled using REPEAT LOAD cases, not load combination cases.

PERFORM ANALYSIS PRINT STATICS CHECK

A static equilibrium report, consisting of total applied loading and total support reactions from each primary load case is requested along with the instructions to carry out a linear static analysis.

PRINT JOINT DISPLACEMENTS LIST 8 9

Global displacements at nodes 8 and 9 are obtained using the above command.

UNIT KNS METER
PRINT SUPPORT REACTIONS

Reactions at the supports are obtained using the above command.

UNIT NEWTON MMS
PRINT ELEMENT JOINT STRESS SOLID LIST 4 6

This command requests the program to provide the element stress results at the nodes of elements 4 and 6. The results will be printed for all the load cases. The word SOLID is used to signify that these are solid elements as opposed to plate or shell elements.

FINISH

The STAAD run is terminated.

**EX. US-25 Analysis of a Structure with Compression-Only Members**

This example demonstrates the usage of compression-only members. Since the structural condition is load dependent, the PERFORM ANALYSIS command is specified once for each primary load case.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-25 Analysis of a Structure with Compression-Only Members.STD when you install the program.
This example has been created to illustrate the command specification for a structure with certain members capable of carrying compressive force only. It is important to note that the analysis can be done for only 1 load case at a time. This is because, the set of “active” members (and hence the stiffness matrix) is load case dependent.

where:

\[
\begin{align*}
L &= 15 \text{ ft, } H = 10 \text{ ft} \\
\text{Load case 1: } P_1 &= 10 \text{ kips} & P_2 &= 15 \text{ kips} \\
\text{Load case 2: } P_3 &= -10 \text{ kips} & P_4 &= -15 \text{ kips}
\end{align*}
\]

**STAAD PLANE**
* EXAMPLE FOR COMPRESSION-ONLY MEMBERS

The input data is initiated with the word STAAD. This structure is a PLANE frame. The second line is an optional comment line.

**UNIT FEET KIP**

Units for the commands to follow are specified above.

**JOINT COORDINATES**

1 0 0 ; 2 0 10 ; 3 0 20 ; 4 15 20 ; 5 15 10 ; 6 15 0

* Figure 479: Example Problem No. 25

**Application Examples**
EX. American Design Examples
Joint coordinates of joints 1 to 6 are defined above.

MEMBER INCIDENCES
1 1 2 5 ; 6 1 5 ; 7 2 6 ; 8 2 4 ; 9 3 5 ; 10 2 5

The members 1 to 10 are defined along with the joints to which they are connected.

MEMBER COMPRESSION
6 TO 9

Members 6 to 9 are defined as COMPRESSION-only members. Hence for each load case, if during the analysis, any of the members 6 to 9 is found to be carrying a tensile force, it is disabled from the structure and the analysis is carried out again with the modified structure.

MEMBER PROPERTY AMERICAN
1 TO 10 TA ST W12X26

Properties for members 1 to 10 are defined as the STandard W12X26 section from the American AISC steel table.

MEMBER PROPERTY BRITISH
1 TO 10 TA ST UC152X152X30

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

SUPPORT
1 6 PINNED

Joints 1 and 6 are declared as pinned-supported.

LOAD 1
JOINT LOAD
2 FX 15
3 FX 10

Load 1 is defined above and consists of joint loads in the global X direction at joints 2 and 3.

PERFORM ANALYSIS

The above structure is analyzed for load case 1.

CHANGE
MEMBER COMPRESSION
6 TO 9

One or more among the members 6 to 9 may have been in-activated in the previous analysis. The CHANGE command restores the original structure to prepare it for the analysis for the next primary load case. The members with the compression-only attribute are specified again.

LOAD 2
JOINT LOAD
In load case 2, joint loads are applied in the negative global X direction at joints 4 and 5.

The instruction to analyze the structure is specified again. Next, any compression-only members that were inactivated during the second analysis (due to the fact that they were subjected to tensile axial forces) are re-activated with the CHANGE command. Without the re-activation, these members cannot be accessed for further processing.

Load case 3 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases already specified earlier. We would like the program to analyze the structure for loads from cases 1 and 2 acting simultaneously. In other words, the above instruction is the same as the following:

The analysis is carried out for load case 3.

The members inactivated during the analysis of load case 3 are re-activated for further processing.

At the end of any analysis, only those load cases for which the analysis was done most recently, are recognized as the “active” load cases. The LOAD LIST ALL command enables all the load cases in the structure to be made active for further processing.

The program is instructed to write the joint displacements, support reactions and member forces to the output file.

The STAAD run is terminated.

51. FINISH
EXAMPLE FOR COMPRESSION-ONLY MEMBERS

*********** END OF THE STAAD.Pro RUN ***********
**** DATE= APR 14,2019   TIME= 22:56:38 ****
EX. US-26 Modeling a Rigid Diaphragm Using Master-Slave

The structure in this example is a building consisting of member columns as well as floors made up of beam members and plate elements. Using the master-slave command, the floors are specified to be rigid diaphragms for in-plane actions but flexible for bending actions.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-26 Modeling a Rigid Diaphragm Using Master-Slave.STD when you install the program.
Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The second line is an optional title to identify this project.

**UNITS KIP FT**

Specify units for the following data.

<table>
<thead>
<tr>
<th>JOINT COORD</th>
<th>1 0 0 4 0 48 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPEAT 3 24 0 0</td>
<td></td>
</tr>
<tr>
<td>REPEAT ALL 3 0 0 24</td>
<td></td>
</tr>
<tr>
<td>DELETE JOINT 21 25 37 41</td>
<td></td>
</tr>
</tbody>
</table>

The joint numbers and coordinates are specified above. The unwanted joints, created during the generation process used above, are then deleted.

<table>
<thead>
<tr>
<th>MEMBER INCI</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 2 3 ; 4 5 6 6 ; 7 9 10 9 ; 10 13 14 12</td>
</tr>
<tr>
<td>13 17 18 15 ; 22 29 30 24 ; 25 33 34 27</td>
</tr>
<tr>
<td>34 45 46 36 ; 37 49 50 39 ; 40 53 54 42</td>
</tr>
<tr>
<td>43 57 58 45 ; 46 61 62 48 ; 49 2 6 51</td>
</tr>
<tr>
<td>52 6 10 54 ; 55 10 14 57 ; 58 18 22 60</td>
</tr>
<tr>
<td>61 22 26 63 ; 64 26 30 66 ; 67 34 38 69</td>
</tr>
<tr>
<td>70 38 42 72 ; 73 42 46 75 ; 76 50 54 78</td>
</tr>
<tr>
<td>79 54 58 81 ; 82 58 62 84 ; 85 18 2 87</td>
</tr>
<tr>

</tr>
<tr>
<td>49 TO 120 TABLE ST W27X84</td>
</tr>
</tbody>
</table>

All members are WIDE FLANGE sections whose properties are obtained from the built in American steel table.

<table>
<thead>
<tr>
<th>ELEMENT PROP</th>
</tr>
</thead>
<tbody>
<tr>
<td>152 TO 178 THICK 0.75</td>
</tr>
</tbody>
</table>

The thickness of the plate elements is specified above.
The **DEFINE MATERIAL** command is used to specify material properties and the **CONSTANT** is used to assign the material to all members. The orientation of some of the members is set using the **BETA** angle command.

The supports at the above mentioned joints are declared as fixed.

The three floors of the structure are specified to act as rigid diaphragms in the ZX plane with the corresponding master joint specified. The associated slave joints in a floor are specified by the **YRANGE** parameter. The floors may still resist out-of-plane bending actions flexibly.

The above data describe a static load case. It consists of joint loads in the global Z direction.
The above data describe a static load case. It consists of joint loads that create a torsional loading on the structure.

**LOADING 3 DEAD LOAD**
**ELEMENT LOAD**
152 TO 178 PRESS GY -1.0

The above data describe a static load case. It consists of plate element pressure on a floor in the negative global Y direction.

**PERFORM ANALYSIS**

The above command instructs the program to proceed with the analysis.

**PRINT JOINT DISP LIST 4 TO 60 BY 8**
**PRINT MEMBER FORCES LIST 116 115**
**PRINT SUPPORT REACTIONS LIST 9 57**

Print displacements at selected joints, then print member forces for two members, then print support reactions at selected joints.

**FINISH**

The STAAD run is terminated.

**EX. US-27 Modeling Soil Springs for a Slab on Grade**

This example illustrates the usage of commands necessary to apply the compression only attribute to spring supports for a slab on grade. The spring supports themselves are generated utilizing the built-in support generation facility. The slab is subjected to pressure and overturning loading. A tension/compression only analysis of the structure is performed.
This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-27 Modeling Soil Springs for a Slab on Grade.STD when you install the program.

The numbers shown in the diagram below are the element numbers.

![Diagram](image)

**Figure 481: Example Problem No. 27**

where:

\[
\begin{align*}
H &= 129', h_1 = 8'-6", h_2 = 8', h_3 = 6' \\
V &= 40', v_1 = 6'-6", v_2 = 6', v_3 = 7'-10", v_4 = 4'
\end{align*}
\]

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. An optional title to identify this project is provided in the second line.

**STAAD SPACE SLAB ON GRADE**

* SPRING COMPRESSION EXAMPLE

This structure has to be analyzed for 3 primary load cases. Consequently, the modeling of our problem requires us to define 3 sets of data, with each set containing a load case and an associated analysis command. Also, the supports which get switched off in the analysis for any load case have to be restored for the analysis for the subsequent load case. To accommodate these requirements, it is necessary to have 2 commands: SET NL and CHANGE. The SET NL command is used above to indicate the total number of primary load cases that the file contains. The CHANGE command will come in later (after the PERFORM ANALYSIS command).

</table>
For joints 1 through 7, the joint number followed by the X, Y and Z coordinates are specified above. The coordinates of these joints is used as a basis for generating 21 more joints by incrementing the X coordinate of each of these 7 joints by 8.5 feet, 3 times. REPEAT commands are used to generate the remaining joints of the structure. The results of the generation may be visually verified using the STAAD graphical viewing facilities.

The incidences of element number 1 is defined and this data is used as a basis for generating the 2nd through the 6th element. The incidence pattern of the first 6 elements is then used to generate the incidences of 96 more elements using the REPEAT command.

The thickness of elements 1 to 102 is specified as 8.0 inches following the command ELEMENT PROPERTIES.

The modulus of elasticity (E) and Poisson's Ratio are specified following the command CONSTANTS.

The above two lines declare the spring supports at nodes 1 to 126 as having the compression-only attribute. The supports themselves are being generated later (see the ELASTIC MAT command which appears later).

The above command is used to instruct STAAD to generate supports with compression-only springs which are effective in the global Y direction. These springs are located at nodes 1 to 126. The subgrade reaction of the soil is specified as 12 kip/cu.ft. The program will determine the area under the influence of each joint and multiply the influence area by the subgrade reaction to arrive at the spring stiffness for the "FY" degree of freedom at the joint. Units for length are changed to FEET to facilitate the input of subgrade reaction of soil. See TR.27.3 Automatic Spring Support Generator for Foundations (on page 2517).
The above data describe a static load case. A pressure load of 1.50 kip/ft acting in the negative global Y direction is applied on all the elements.

Tension/compression cases must each be followed by PERFORM ANALYSIS and CHANGE commands. The CHANGE command restores the original structure to prepare it for the analysis for the next primary load case.

Load case 2 consists of several joint loads acting in the negative global Y direction. This is followed by another ANALYSIS command. The CHANGE command restores the original structure once again for the forthcoming load case.
Load case 3 consists of several joint loads acting in the upward direction at one end and downward on the other end to apply an overturning moment that will lift off one end. The CHANGE command is not needed after the last analysis.

A list of joint displacements, element stresses for elements 34 and 67, and support reactions at a list of joints for load case 3, are obtained with the help of the above commands.

The STAAD run is terminated.

EX. US-28 Calculation of Modes and Frequencies of a Bridge

This example demonstrates the input required for obtaining the modes and frequencies of the skewed bridge shown in the figure below. The structure consists of piers, pier-cap girders and a deck slab.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-28 Calculation of Modes and Frequencies of a Bridge.std when you install the program.

Figure 482: Example Problem No. 28

STAAD SPACE FREQUENCIES OF VIBRATION OF A SKEWED BRIDGE

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The remainder of the words forms a title to identify this project.

IGNORE LIST

Further below in this file, we will call element lists in which some element numbers may not actually be present in the structure. We do so because it minimizes the effort involved in fetching the desired elements and reduces
the size of the respective commands. To prevent the program from treating that condition (referring to elements which do not exist) as an error, the above command is required.

UNIT METER KN

The units for the data that follows are specified above.

JOINT COORDINATES
1 0 0 0; 2 4 0 0; 3 6.5 0 0; 4 9 0 0; 5 11.5 0 0; 6 15.5 0 0;
11 -1 0 25 16.5 10 0
REPEAT ALL 3 4 0 14

For joints 1 through 6, the joint number followed by the X, Y and Z coordinates are specified first. Next, using the coordinates of joints 11 and 25 as the basis, joints 12 through 24 are generated using linear interpolation.

Following this, using the data of these 21 joints (1 through 6 and 11 through 25), 63 new joints are generated. To achieve this, the X coordinate of these 21 joints is incremented by 4 meters and the Z coordinate is incremented by 14 meters, in 3 successive operations.

The REPEAT ALL command is used for the generation. Details of this command is available in TR.11 Joint Coordinates Specification (on page 2425). The results of the generation may be visually verified using STAAD.Pro's graphical viewing facilities.

MEMBER INCI
1 1 13 ; 2 2 15 ; 3 3 17 ; 4 4 19 ; 5 5 21 ; 6 6 23
26 26 34 ; 27 27 36 ; 28 28 38 ; 29 29 40 ; 30 30 42 ; 31 31 44
47 47 55 ; 48 48 57 ; 49 49 59 ; 50 50 61 ; 51 51 63 ; 52 52 65
68 68 76 ; 69 69 78 ; 70 70 80 ; 71 71 82 ; 72 72 84 ; 73 73 86

The member connectivity data (joint numbers between which members are connected) is specified for the 24 columns for the structure. The above method, where the member number is followed by the 2 node numbers, is the explicit definition method. No generation is involved here.

101 11 12 114
202 32 33 215
303 53 54 316
404 74 75 417

The member connectivity data is specified for the pier cap beams for the structure. The above method is a combination of explicit definition and generation. For example, member 101 is defined as connected between 11 & 12. Then, by incrementing those nodes by 1 unit at a time (which is the default increment), the incidences of members 102 to 114 are generated. Similarly, we create members 202 to 215, 303 to 316, and, 404 to 417.

DEFINE MESH
A JOINT 11
B JOINT 25
C JOINT 46
D JOINT 32
E JOINT 67
F JOINT 53
G JOINT 88
H JOINT 74

The next step is to generate the deck slab which will be modeled using plate elements. For this, we use a technique called mesh generation. Mesh generation is a process of generating several "child" elements from a "parent" or "super" element. The above set of commands defines the corner nodes of the super-element. Details of the above can be found in Section 5.14 of the Technical Reference manual.
Note that instead of elaborately defining the coordinates of the corner nodes of the super-elements, we have taken advantage of the fact that the coordinates of these joints (A through H) have already been defined or generated earlier. Thus, A is the same as joint 11 while D is the same as joint 32. Alternatively, we could have defined the super-element nodes as A 1 10 0; B 16.5 10 0; C 20.5 10 14; D 3 10 14; etc.

<table>
<thead>
<tr>
<th>GENERATE ELEMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>MESH ABCD 14 12</td>
</tr>
<tr>
<td>MESH DCEF 14 12</td>
</tr>
<tr>
<td>MESH FEGH 14 12</td>
</tr>
</tbody>
</table>

The above lines are the instructions for generating the “child” elements from the super-elements. For example, from the super-element bound by the corners A, B, C and D (which in turn are nodes 11, 25, 46 and 32), we generate a total of 14X12=168 elements, with 14 divisions along the edges AB and CD, and 12 along the edges BC and DA. These are the elements which make up the first span.

Similarly, 168 elements are created for the 2nd span, and another 168 for the 3rd span.

It may be noted here that we have taken great care to ensure that the resulting elements and the piercap beams form a perfect fit. In other words, there is no overlap between the two in a manner that nodes of the beams are at a different point in space than nodes of elements. At every node along their common boundary, plates and beams are properly connected. This is absolutely essential to ensure proper transfer of load and stiffness from beams to plates and vice versa. The tools of the graphical user interface may be used to confirm that beam-plate connectivity is proper for this model.

</tbody>
</table>

The above block of data is referred to as formation of groups. Group names are a mechanism by which a single moniker can be used to refer to a cluster of entities, such as members. For our structure, the piercap beams are being grouped to a name called GIRDERS, the pier columns are assigned the name PIERS, and so on. For the deck, a few selected elements are chosen into a few selective groups. The reason is that these elements happen to be right beneath wheels of vehicles whose weight will be used in the frequency calculation.

The Modulus of elasticity \((E)\) is set to 21000 N/sq.mm for all members. The keyword \textit{CONSTANTS} has to precede this data. Built-in default value for Poisson’s ratio for concrete is also assigned to \textit{ALL} members and elements.

Following a change of units, density of concrete is specified.

The base nodes of the piers are fully restrained (FIXED supports).

Theoretically, a structure has as many modes of vibration as the number of degrees of freedom in the model. However, the limitations of the mathematical process used in extracting modes may limit the number of modes that can actually be extracted. In a large structure, the extraction process can also be very time consuming. Further, not all modes are of equal importance. (One measure of the importance of modes is the participation factor of that mode.) In many cases, the first few modes may be sufficient to obtain a significant portion of the total dynamic response.

Due to these reasons, in the absence of any explicit instruction, STAAD calculates only the first 6 modes. This is like saying that the command \texttt{CUT OFF MODE SHAPE 6} has been specified. (Versions of STAAD prior to STAAD.Pro 2000 calculated only 3 modes by default).

If the inspection of the first 6 modes reveals that the overall vibration pattern of the structure has not been obtained, one may ask STAAD to compute a larger (or smaller) number of modes with the help of this command. The number that follows this command is the number of modes being requested. In our example, we are asking for 65 modes by specifying \texttt{CUT OFF MODE SHAPE 65}.

</table>
The mathematical method that STAAD uses is called the eigen extraction method. Some information on this is available in G.17.3 Dynamic Analysis (on page 2362). The method involves 2 matrices - the stiffness matrix, and the mass matrix.

The stiffness matrix, usually called the \([K]\) matrix, is assembled using data such as member and element lengths, member and element properties, modulus of elasticity, Poisson’s ratio, member and element releases, member offsets, support information, etc.

For assembling the mass matrix, called the \([M]\) matrix, STAAD uses the load data specified in the load case in which the MODAL CAL REQ command is specified. So, some of the important aspects to bear in mind are:

1. The input you specify is weights, not masses. Internally, STAAD will convert weights to masses by dividing the input by “g”, the acceleration due to gravity.

2. If the structure is declared as a PLANE frame, there are 2 possible directions of vibration - global X, and global Y. If the structure is declared as a SPACE frame, there are 3 possible directions - global X, global Y and global Z. However, this does not guarantee that STAAD will automatically consider the masses for vibration in all the available directions.

   You have control over and are responsible for specifying the directions in which the masses ought to vibrate. In other words, if a weight is not specified along a certain direction, the corresponding degrees of freedom (such as for example, global X at node 34 hypothetically) will not receive a contribution in the mass matrix. The mass matrix is assembled using only the masses from the weights and directions you specify.

   In our example, notice that we are specifying the self-weight along global X, Y and Z directions. Similarly, a 200 kg/sq.m pressure load is also specified along all 3 directions on the deck.

   But for the truck loads, we choose to apply it on just a few elements in the global Y and Z directions only. The reasoning is something like - for the X direction, the mass is not capable of vibrating because the tires allow the truck to roll along X. Remember, this is just a demonstration example, not necessarily what you may want to do.

   The point we want to illustrate is that if a user wants to restrict a certain weight to certain directions only, all he/she has to do is not provide the directions in which those weights cannot vibrate in.

3. As much as possible, provide absolute values for the weights. STAAD is programmed to algebraically add the weights at nodes. So, if some weights are specified as positive numbers and others as negative, the total weight at a given node is the algebraic summation of all the weights in the global directions at that node and the mass is then derived from this algebraic resultant.

   MODAL CALCULATION REQUESTED

This is the command which tells the program that frequencies and modes should be calculated. It is specified inside a load case. In other words, this command accompanies the loads that are to be used in generating the mass matrix.

Frequencies and modes have to be calculated also when dynamic analysis such as response spectrum or time history analysis is carried out. But in such analyses, the MODAL CALCULATION REQUESTED command is not explicitly required. When STAAD encounters the commands for response spectrum (see example 11) and time
history (see examples 16 and 22), it automatically will carry out a frequency extraction without the help of the MODAL.. command.

**PERFORM ANALYSIS**

This initiates the processes which are required to obtain the frequencies. Frequencies, periods and participation factors are automatically reported in the output file when the operation is completed.

**FINISH**

This terminates the STAAD run.

Understanding the output

After the analysis is complete, look at the output file. (This file can be viewed by selecting the Analysis Output tool in the View group on the Utilities ribbon tab).

i. Mode number and corresponding frequencies and periods

Since we asked for 65 modes, we obtain a report, a portion of which is as shown:

### Table 657: Calculated Frequencies for Load Case 1

</tbody>
</table>
In the explanation earlier for the **CUT OFF MODE** command, we said that one measure of the importance of a mode is the participation factor of that mode. We can see from the above report that for vibration along Z direction, the first mode has a 99.04 percent participation. It is also apparent that the 7th mode is primarily a Y direction mode with a 26.42% participation along Y and 0 in X and Z.

The **ΣX**, **ΣY** and **ΣZ** columns show the cumulative value of the participation of all the modes up to and including a given mode (Corresponding to the SUMM-X, SUMM-Y, and SUMM-Z reported in the output, respectively). One can infer from those terms that if one is interested in 95% participation along X, the first 2 modes are sufficient.

But for the Y direction, even with 10 modes, we barely obtained 60%. The reason for this can be understood by an examination of the nature of the structure. The deck slab is capable of vibrating in several low energy and primarily vertical direction modes. The out-of-plane flexible nature of the slab enables it to vibrate in a manner resembling a series of wave like curves. Masses on either side of the equilibrium point have opposing eigenvector values leading to a lot of cancellation of the contribution from the respective masses. Localized modes, where small pockets in the structure undergo flutter due to their relative weak stiffness compared to the rest of the model, also result in small participation factors.

**iii.** After the analysis is completed, select Post-processing from the mode menu. This screen contains facilities for graphically examining the shape of the mode in static and animated views. The Dynamics page on the left side of the screen is available for viewing the shape of the mode statically. The Animation option of the Results menu can be used for animating the mode. The mode number can be selected from the **Loads and Results** tab of the **Diagrams** dialog box which opens when the Animation option is chosen. The size to which the mode is drawn is controlled using the **Scales** tab of the **Diagrams** dialog box.

**EX. US-29 Time History Analysis of a Frame for Seismic Loads**

Analysis and design of a structure for seismic loads is demonstrated in this example. In this model, static load cases are solved along with the seismic load case. For the seismic case, the maximum values of displacements,
forces and reactions are obtained. The results of the dynamic case are combined with those of the static cases and steel design is performed on the combined cases.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\US-29 Time History Analysis of a Frame for Seismic Loads.std when you install the program.

Figure 483: Example Problem No. 29

Actual input is shown in bold lettering followed by explanation.

STAAD SPACE DYNAMIC ANALYSIS FOR SEISMIC LOADS

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The remainder of the words form a title to identify this project.

UNIT METER KNS

The units for the data that follows are specified above.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 0 ; 2 0 3.5 0 ; 3 0 5.3 0 ; 4 0 7 0</td>

<tr>
<td>REPEAT ALL 1 9.5 0 0</td>
</tr>
<tr>
<td>REPEAT ALL 1 0 0 3</td>
</tr>
<tr>
<td>17 1.8 7 0 ; 18 4.6 7 0 ; 19 7.6 7 0</td>
</tr>
<tr>
<td>REPEAT ALL 1 0 0 3</td>
</tr>
</tbody>
</table>

For joints 1 through 4, the joint number is followed by the X, Y and Z coordinates as specified above. The coordinates of these joints are used as a basis for generating 12 more joints by incrementing the X & Z coordinates by specific amounts. REPEAT ALL commands are used for the generation. Details of these commands are available in Section 5.11 of the Technical Reference manual. Following this, another round of
explicit definition (joints 17, 18 & 19) and generation (20, 21 & 22) is carried out. The results of the generation may be visually verified using graphical view features in STAAD.Pro.

MEMBER INCIDENCES
1 1 2 3
REPEAT 1 3 4
7 9 10 9
10 13 14 12
13 4 17; 14 17 18; 15 18 19; 16 19 8
17 12 20; 18 20 21; 19 21 22; 20 22 16
21 2 10; 22 4 12; 23 6 14
24 8 16; 25 3 17; 26 7 19; 27 11 20; 28 15 22; 29 18 21

A mixture of explicit definition and generation of member connectivity data (joint numbers between which members are connected) is used to generate 29 members for the structure.

START GROUP DEFINITION
MEMBER
_Vertical 1 TO 12
_Xbeam 13 TO 20
_Zbeam 21 TO 24 29
_Brace 25 TO 28
END GROUP DEFINITION

The above block of data is referred to as formation of groups. Group names are a mechanism by which a single moniker can be used to refer to a cluster of entities, such as members. For our structure, the columns are being grouped to a name called VERTICAL, the beams running along the X direction are assigned the name XBEAM, and so on.

MEMBER PROPERTIES CANADIAN
_Vertical TA ST W310X97
_Xbeam TA ST W250X39
_Zbeam TA ST C200X17
_Brace TA ST L152X152X13

Member properties are assigned from the Canadian steel table. The members which receive these properties are those embedded within the respective group names. The benefit of using the group name is apparent here. Just from the looks of the command, we can understand that the diagonal braces are being assigned a single angle. The alternative, which would be

25 TO 28 TA ST L152X152X13

would have required us to go to the graphical tools to get a sense of what members 25 to 28 are.

The bottom ends of the columns of the platform are pinned supported.

| CUT OFF MODE SHAPE | 30 |

The above command is a critical command if you want to override the default number of modes computed and used in a dynamic analysis. The default, which is 6, may not always be sufficient to capture a significant portion of the structural response in a response spectrum or time history analysis, and hence the need to override the default. This command is explained in Section 5.30 of the Technical Reference manual.

| UNIT METER DEFINE TIME HISTORY TYPE 1 ACCELERATION READ EQDATA.TXT ARRIVAL TIME 0.0 DAMPING 0.05 |

There are two stages in the command specification required for a time-history analysis. The first stage is defined above. Here, the parameters of the earthquake (ground acceleration) are provided.

Each data set is individually identified by the number that follows the TYPE command. In this file, only one data set is defined, which is apparent from the fact that only one TYPE is defined.

The word FORCE that follows the TYPE 1 command signifies that this data set is for a ground acceleration. (If you want to specify a forcing function, the keyword FORCE must be used instead.)

Notice the expression READ EQDATA.TXT. It means that we have chosen to specify the time vs. ground acceleration data in the file called EQDATA.TXT. That file must reside in the same folder as the one in which the data file for this structure resides. As explained in the small examples shown in TR.31.4 Definition of Time History Load (on page 2630), the EQDATA.TXT file is a simple text file containing several pairs of time-acceleration data. A sample portion of that file is as shown below.

| 0.0000 | 0.006300 |
| 0.0200 | 0.003640 |
| 0.0400 | 0.000990 |
| 0.0600 | 0.004280 |
| 0.0800 | 0.007580 |
| 0.1000 | 0.010870 |

While it may not be apparent from the above numbers, it may also be noted that the geological data for the site the building sits on indicate that the above acceleration values are a fraction of "g", the acceleration due to gravity. Thus, for example, at 0.02 seconds, the acceleration is 0.00364 multiplied by 9.806 m/sec² (or 0.00364 multiplied by 32.2 ft/sec²). Consequently, the burden of informing the program that the values need to be multiplied by "g" is upon us, and we shall do so at a later step.

The arrival time value indicates the relative value of time at which the earthquake begins to act upon the structure. We have chosen 0.0, as there is no other dynamic load on the structure from the relative time standpoint. The modal damping ratio for all the modes is set to 0.05.

| LOAD 1 WEIGHT OF STRUCTURE ACTING STATICALLY SELFWEIGHT Y -1.0 |
The above data describe a static load case. The selfweight of the structure is acting in the negative global Y direction.

Load case 2 is also a static load case. At the Y=7.0m elevation, our structure has a floor slab. But, it is a non-structural entity which, though capable of carrying the loads acting on itself, is not meant to be an integral part of the framing system. It merely transmits the load to the beam-column grid.

There are uniform area loads on the floor (think of the load as wooden pallets supporting boxes of paper). Since the slab is not part of the structural model, how do we tell the program to transmit the imposed load from the slab to the beams without manually converting them to distributed beam loads ourselves? That is where the floor load utility comes in handy. It is a facility where we specify the load as a pressure, and the program converts the pressure to individual beam loads. Thus, the input required is very simple - load intensity in the form of pressure, and the region of the structure in terms of X, Y and Z coordinates in space, of the area over which the pressure acts.

In the process of converting the pressure to beam loads, STAAD will consider the empty space between criss-crossing beams (in plan view) to be panels, similar to the squares of a chess board. The load on each panel is then transferred to beams surrounding the panel, using a triangular or trapezoidal load distribution method.

Load case 3 is the dynamic load case, the one which contains the second part of the instruction set for a dynamic analysis to be performed. The data here are

a. loads which will yield the mass values which will populate the mass matrix
b. the directions of the loads, which will yield the degree of freedom numbers of the mass matrix for being populated.

Thus, the selfweight, as well as the imposed loads on the non-structural slab are to be considered as participating in the vibration along all the global directions.

The above command too is part of load case 3. Here we say that the seismic force, whose characteristics are defined by the TYPE 1 time history input data, acting at arrival time 1, is to be applied along the X direction. We mentioned earlier that the acceleration input data was specified as a fraction of “g”. The number 9.806 indicates the value which the acceleration data, as read from EQDATA.TXT are to be factored by before they are used.

In a time history analysis, the member forces FX thru MZ each have a value for every time step. If there are 1000 time steps, there will be 1000 values of FX, 1000 for FY etc. for that load case. Not all of them can be used in a further calculation like a steel or concrete design. However, the maximum from among those time steps is available. If we want to do a design, one way to make sure that the structure is not under-designed is to create 2 load combination cases involving the dynamic case, a positive combination, and a negative combination.
That is what is being done above. Load combination case no. 11 consists of the sum of the static load cases (1 & 2) with the positive direction of the dynamic load case (3). Load combination case no. 12 consists of the sum of the static load cases (1 & 2) with the negative direction of the dynamic load case (3). The user has discretion on what load factors to use with these combinations. We have chosen the factors to be 1.0.

**PERFORM ANALYSIS**

The above is the instruction to perform the analysis related calculations. That means, computing nodal displacements, support reactions, etc.

**PRINT ANALYSIS RESULTS**

The above command is an instruction to the program to produce a report of the joint displacements, support reactions and member end forces in the output file. As mentioned earlier, for the dynamic case, these will be just the maximum values, not the ones generated for every time step. If you want to see the results for each time step, you may do so by using STAAD's Post-processing facilities.

EX. British Design Examples

EX. UK-1 Plane Frame with Steel Design

After one analysis, member selection is requested. Since member sizes change during the member selection, another analysis is done followed by final code checking to verify that the final sizes meet the requirements of the code based on the latest analysis results.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-1 Plane Frame with Steel Design.STD when you install the program.
where:

\[
L = 4.5 \, \text{m}, \quad H_1 = 6.0 \, \text{m}, \quad H_2 = 4.5 \, \text{m}, \quad \text{and} \quad H_3 = 2.7 \, \text{m}
\]
\[
WL_x = 9.0 \, \text{KN/m}, \quad WL_y = 15 \, \text{KN/m}, \quad RL = 13.5 \, \text{KN/m}, \quad LL = 17.5 \, \text{KN/m}, \quad P_1 = 135 \, \text{KN}, \quad P_2 = 35 \, \text{KN}
\]

Members 1, 3, & 4 are a UC356X368X129, Members 5, 6, & 7 are a UB533X210X82, Member 2 is a UC254X254X73, Members 8 through 13 are a UB457X152X52. All other members comprising the truss are a UA100X100X8

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE EXAMPLE PROBLEM NO. 1**

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

**UNIT METER KN**
Defines the input units for the data that follows.

**JOINT COORDINATES**

```
1 0 0 ; 2 9 0 ; 3 0 6 ; 4 3 6
5 6 6 ; 6 9 6 ; 7 0 10.5
8 9 10.5 ; 9 2.25 10.5 ; 10 6.75 10.5
11 4.5 10.5 ; 12 1.5 11.4 ; 13 7.5 11.4
14 3 12.3 ; 15 6 12.3 ; 16 4.5 13.2
```

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

**MEMBER INCIDENCE**

```
1 1 3 ; 2 3 7 ; 3 2 6 ; 4 6 8 ; 5 3 4
6 4 5 ; 7 5 6 ; 8 7 12 ; 9 12 14
10 14 16 ; 11 15 16 ; 12 13 15 ; 13 8 13
14 9 12 ; 15 9 14 ; 16 11 14 ; 17 11 15
18 10 15 ; 19 10 13 ; 20 7 9
21 9 11 ; 22 10 11 ; 23 8 10
```

Defines the members by the joints to which they are connected.

**MEMBER PROPERTY BRITISH**

```
1 3 4 TA ST UC356X368X129 ; 2 TA ST UC254X254X73
5 6 7 TA ST UB533X210X82 ; 8 TO 13 TA ST UB457X152X52
14 TO 23 TA ST UA100X100X8
```

Member properties are from the British steel table. The term ST stands for standard single section.

**MEMB TRUSS**

```
14 TO 23
```

The above command defines that members 14 through 23 are of type truss. This means that these members can carry only axial tension/compression and no moments.

**MEMB RELEASE**

```
5 START MZ
```

Member 5 has local moment-z (MZ) released at the start joint. This means that the member cannot carry any moment-z (i.e., strong axis moment) at node 3.

**UNIT KNS MMS**

```
DEFINE MATERIAL START
ISOTROPIC STEEL
E 210
POISSON 0.3
DENSITY 7.68191e-008
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 0.24821 FU 0.399894 RY 1.5 RT 1.2
END DEFINE MATERIAL
```

The DEFINE MATERIAL START initiates input for a material definition, which can later be assigned to all members. STAAD.Pro has several built-in material definitions, including the ISOTROPIC STEEL material used here. The length unit is changed to MMS (millimeters) to facilitate the input in familiar units.
MATERIAL STEEL ALL
UNIT METER

The CONSTANT command initiates input for material constants or material definition references. The BETA command specifies that members 3 and 4 are rotated by 90 degrees around their own longitudinal axis. See G. 4.3 Relationship Between Global and Local Coordinates (on page 2301) for the definition of the beta angle.

SUPPORT
1 FIXED ; 2 PINNED

A fixed support is located at joint 1 and a pinned support at joint 2.

PRINT MEMBER INFORMATION LIST 1 5 14
PRINT MEMBER PROPERTY LIST 1 2 5 8 14

The above PRINT commands are self-explanatory. The LIST option restricts the print output to the members listed.

LOADING 1 DEAD AND LIVE LOAD

Load case 1 is initiated followed by a title.

SELFWEIGHT Y -1.0

One of the components of load case 1 is the selfweight of the structure acting in the global Y direction with a factor of -1.0. Since global Y is vertically upward, the factor of -1.0 indicates that this load will act downwards.

JOINT LOAD
4 5 FY -65. ; 11 FY -155.

Load 1 contains joint loads also. FY indicates that the load is a force in the global Y direction.

MEMB LOAD
8 TO 13 UNI Y -13.5 ; 6 UNI GY -17.5

Load 1 contains member loads also. GY indicates that the load is in the global Y direction while Y indicates local Y direction. The term UNI stands for uniformly distributed load. Loads are applied on members 6, and 8 to 13.

CALCULATE RAYLEIGH FREQUENCY

The above command at the end of load case 1, is an instruction to perform a natural frequency calculation based on the Rayleigh method using the data in the above load case.

LOADING 2 WIND FROM LEFT
MEMBER LOAD
1 2 UNI GX 9.0 ; 8 TO 10 UNI Y -15.0

Load case 2 is initiated and contains several member loads.

* 1/3 RD INCREASE IS ACCOMPLISHED BY 75% LOAD LOAD COMB 3 75 PERCENT DL LL WL
1 0.75 2 0.75

The above command identifies a combination load (case no. 3) with a title. The second line provides the load cases and their respective factors used for the load combination.

Note: Any line beginning with an asterisk (* character) is treated as a comment line.

PERFORM ANALYSIS

This command instructs the program to proceed with the analysis.

LOAD LIST 1 3
The above command activates load cases 1 and 3 only for the commands to follow. This also means that load case 2 will be made inactive.

```
PRINT MEMBER FORCES
PRINT SUPPORT REACTION
```

The above PRINT commands are self-explanatory. Also note that all the forces and reactions will be printed for load cases 1 and 3 only.

```
PARAMETER
CODE EN 1993-1-1:2005
NA 1
NSF 0.85 ALL
BEAM 1 ALL
KY 1.2 MEMB 3 4
RATIO 0.9 ALL
```

The PARAMETER command is used to specify steel design parameters such as net section factor (NSF), effective length factor for bending about the minor axis (KY), etc. Information on these parameters can be obtained from the manual where the implementation of the code is explained. The BEAM parameter is specified to perform design at every 1/12th point along the member length, which is also the default. The RATIO parameter specifies that the ratio of actual loading over section capacity should not exceed 0.9.

```
SELECT ALL
```

The above command instructs the program to select the most economic section for all the members based on the results of the analysis.

```
GROUP MEMB 1 3 4
GROUP MEMB 5 6 7
GROUP MEMB 8 TO 13
GROUP MEMB 14 TO 23
```

Although the program selects the most economical section for all members, it is not always practical to use many different sizes in one structure. Grouping is a procedure by which the cross section which has the largest value for the specified attribute, which in this case is the default and hence the AREA, from among the associated member list, is assigned to all members in the list. Hence, the cross sections for members 1, 3 and 4 are replaced with the one with the largest area from among the three.

```
PERFORM ANALYSIS
```

As a result of the selection and grouping, the member sizes are no longer the same as the ones used in the original analysis. Hence, it is necessary to reanalyze the structure using the new properties to get new values of forces in the members.

```
PARAMETER
BEAM 1.0 ALL
RATIO 1.0 ALL
TRACK 1.0 ALL
```

A new set of values are now provided for the above parameters. The actual load to member capacity RATIO has been redefined as 1.0. The TRACK parameter tells the program to print out the design results to the intermediate level of descriptively.

```
CHECK CODE ALL
```

With the above command, the latest member sizes with the latest analysis results are checked to verify that they satisfy the CODE specifications.

```
STEEL TAKE OFF
```
This command instructs the program to list the length and weight of all the different member sizes.

**FINISH**

This command terminates the STAAD run.

### Application Examples

**EX. British Design Examples**

---

**Application Examples**

**EX. British Design Examples**
EX. UK-2 Area Load Generation on Floor Structure

A floor structure (bound by global X-Z axis) made up of steel beams is subjected to area load (i.e., load/area of floor). Load generation based on one-way distribution is illustrated in this example.

In the case of loads such as joint loads and member loads, the magnitude and direction of the load at the applicable joints and members is directly known from the input. However, the area load is a different sort of load where a load intensity on the given area has to be converted to joint and member loads. The calculations required to perform this conversion are done only during the analysis. Consequently, the loads generated from the AREA LOAD command can be viewed only after the analysis is completed.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-2 Area Load Generation on Floor Structure.STD when you install the program.
Where:

\[ W1 = 1.5 \text{ m}, W2 = 1.0 \text{ m}, W3 = 1.5 \text{ m}, L1 = 2.0 \text{ m}, L2 = 4.5 \text{ m}, L3 = 3.0 \text{ m} \]

Actual input is shown in bold lettering followed by explanation.

**STAAD FLOOR A FLOOR FRAME DESIGN WITH AREA LOAD**

Every input has to start with the term STAAD. The term FLOOR signifies that the structure is a floor structure and the structure is in the \( x-z \) plane.

**UNIT METER KNS**

Defines the input units for the data that follows.

**JOINT COORDINATES**

\[
\begin{align*}
1 & 0 & 0 & 0 & 5 & 6 & 0 & 0 & ; & 7 & 1.5 & 0 & 3 \\
8 & 3 & 0 & 3 & ; & 9 & 4 & 0 & 3 & ; & 10 & 4.5 & 0 & 3 & ; & 11 & 5 & 0 & 3 \\
12 & 6 & 0 & 3 & ; & 13 & 0 & 0 & 7.5 & ; & 14 & 1.5 & 0 & . & 7.5 \\
15 & 3.5 & 0 & 7.5
\end{align*}
\]
Joint numbers followed by X, Y and Z coordinates are provided above. Since this is a floor structure, the Y coordinates are all the same (in this case, zero). Joints between 1 and 5 (i.e., 2, 3, 4) are generated in the first line of input, taking advantage of the equal spacing between the joints (see TR.11 Joint Coordinates Specification (on page 2425) for more information).

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCES
1 1 2 4 ; 5 7 8 9 ; 10 13 14 13 ; 14 18 19
15 20 21 ; 16 18 20 ; 17 13 18 ; 18 1 13
19 7 14 ; 20 2 7 ; 21 9 15
22 3 8 ; 23 11 16 ; 24 4 10 ; 25 19 21
26 17 19 ; 27 12 17 ; 28 5 12

Defines the members by the joints to which they are connected.

MEMB PROP BRITISH
1 TO 28 TABLE ST UB305X165X40

Member properties are specified from the British steel table. The term ST stands for standard single section.

* MEMBERS WITH PINNED ENDS ARE RELEASED FOR MZ
MEMB RELEASE
1 5 10 14 15 18 26 20 TO 24 START MZ
4 9 13 14 15 18 27 25 19 21 TO 24 END MZ

The first set of members (1 5 10 etc) have local moment-z (MZ) released at the start joint. This means that these members cannot carry any moment-z (i.e., strong axis moment) at the start joint. The second set of members have MZ released at the end joints.

Note: Any line beginning with an asterisk (*) character is treated as a comment line.

END DEFINE MATERIAL
UNIT METER

Define the material properties for steel. The units are changed to millimeters and then back to meters in order to facilitate inputting the values in familiar units.

CONSTANT
MATERIAL STEEL ALL

The CONSTANT command instructs the program to use the defined steel material for all members.

SUPPORT
1 5 13 17 20 21 FIXED
A fixed support has been specified at the above joints.

**LOADING 1 14.5 KN/sq.m. DL+LL**

Load case 1 is initiated followed by a title.

**FLOOR LOAD**

**YRANGE -0.5 0.5 FLOAD -14.5**

All members within a range of -0.5 meters to 0.5 meters in the global Y direction (which is the entire floor of this model) are subjected to an floor load of 14.5 KN/sq.m. The program converts area loads into individual member loads.

**PERFORM ANALYSIS PRINT LOAD DATA**

This command instructs the program to proceed with the analysis. The PRINT LOAD DATA command is specified to obtain a listing of the member loads which were generated from the FLOOR LOAD.

**PARAMETERS**

**CODE BRITISH**

**BEAM 1 ALL**

**DMAX 0.6 ALL**

**DMIN 0.3 ALL**

**UNL 0.3 ALL**

The PARAMETER command is used to specify steel design parameters (See Table 1 in D3.B.6 Design Parameters on page 1661). Design is to be performed per the specifications of the BS 5950 2000 Code. The BEAM parameter is specified to perform design at every 1/12th point along the member length. DMAX and DMIN specify maximum and minimum depth limitations to be used during member selection. UNL is used to specify unsupported length of the compression flange to be used for calculation of allowable bending stress.

**SELECT MEMB 2 6 11 14 15 16 18 19 21 23 24 27**

The above command instructs the program to select the most economical section from the British steel table for the members listed.

**FINISH**

The FINISH command terminates the STAAD run.

EX. UK-3 Soil Springs for Portal Frame

A portal frame type steel structure is sitting on concrete footings. The soil is to be considered as an elastic
foundation. The value of soil subgrade reaction is known from which spring constants are calculated by
multiplying the subgrade reaction by the tributary area of each modeled spring.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-3 Soil
Springs for Portal Frame.STD when you install the program.
Figure 485: Example Problem No. 3

Where:

\[ B = 6 \text{ m}, \quad H = 3 \text{ m}, \quad F_1 = 1.2 \text{ m}, \quad F_2 = 2.4 \text{ m} \]
\[ P = 20 \text{ KN}, \quad w = 4.5 \text{ KN/m} \]
Soil Subgrade Reaction = 41,666.67 KN/m³

Table 659: Spring constant calculation

</thead>
<tbody>
<tr>
<td>1, 5, 10, &amp; 14 (Edges)</td>
<td>2.4 x 0.3 x 41,666.67 = 30,000 KN/m</td>
</tr>
<tr>
<td>2, 3, 4, 11, 12, &amp; 13 (Interior)</td>
<td>2.4 x 0.6 x 41,666.67 = 60,000 KN/m</td>
</tr>
</tbody>
</table>

Actual input is shown in bold lettering followed by explanation.
Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

UNIT METER KNS

Defines the input units for the data that follows.

JOINT COORDINATES
1 0.0 0.0 0.0 5 2.4 0.0 0.0
6 1.2 3.0 0.0 ; 7 1.2 6.0 0.0
8 7.2 6.0 0.0 ; 9 7.2 3.0 0.0
10 6.0 0.0 0.0 14 8.4 0.0 0.0

Joint number followed by X, Y and Z coordinates are provided above. Since this is a plane structure, the Z coordinates are given as all zeros.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCES
1 1 2 4
5 3 6 ; 6 6 7
7 7 8 ; 8 6 9
9 8 9 ; 10 9 12
11 10 11 14

Defines the members by the joints to which they are connected.

MEMBER PROPERTIES BRITISH
1 4 11 14 PRIS YD 0.30 ZD 2.40
2 3 12 13 PRIS YD 0.60 ZD 2.40
5 6 9 10 TABLE ST J0254X203
7 8 TA ST UB305X165X40

The first two lines define member properties as prismatic (PRIS) followed by depth (YD) and width (ZD) values. The program will calculate the properties necessary to perform the analysis. See G.6.1 Prismatic Properties (on page 2323) for additional information. Member properties for the remaining members are chosen from the British steel table. The term ST stands for standard single section.

END DEFINE MATERIAL
CONSTANTS
The CONSTANT command initiates input for material constants like modulus of elasticity, Density, and Poisson's ratio. The length unit is changed from METER to MM to facilitate the input in familiar units.

**Note:** Any line beginning with an asterisk (*) character is treated as a comment line.

The supports for the structure are specified above. The first set of joints are supports restrained in all directions except global moment-z (MZ). Also, a spring having a spring constant of 60 KN/mm is provided in the global Y direction at these nodes. The second set is similar to the former except for a different value of the spring constant.

Load case 1 is initiated followed by a title.

The selfweight of the structure is specified as acting in the global Y direction with a -1.0 factor.

Since global Y is vertically upwards, the -1.0 factor indicates that this load will act downwards.

Load 1 contains joint loads also. FX indicates that the load is a force in the global X direction.

Load 1 contains member loads also. GY indicates that the load acts in the global Y direction. The term UNI stands for uniformly distributed load, and is applied on members 7 and 8, acting downwards.

This command instructs the program to proceed with the analysis.

The above PRINT command instructs the program to print analysis results which include joint displacements, member forces and support reactions.

This command terminates the STAAD run.

**EX. UK-4 Inactive Members in a Braced Frame**

This example is a typical case of a load-dependent structure where the structural condition changes for different load cases. In this example, different bracing members are made inactive for different load cases. This is done to prevent these members from carrying any compressive forces.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-4 Inactive Members in a Braced Frame.STD when you install the program.
Where:

\[ L_1 = 4.5 \text{ m}, L_2 = 6.0 \text{ m} \]
\[ P_1 = 45 \text{ kN}, P_2 = 90 \text{ kN} \]

Actual input is shown in bold lettering followed by explanation.

```
STAAD PLANE
* A PLANE FRAME STRUCTURE WITH TENSION BRACING

UNIT METER KNS
```

Defines the input units for the data that follows.

```
SET NL 3
```

This structure has to be analyzed for three primary load cases. Consequently, the modeling of our problem requires us to define three sets of data, with each set containing a load case and an associated analysis command. Also, the members which get switched off in the analysis for any load case have to be restored for the analysis for the subsequent load case. To accommodate these requirements, it is necessary to have two commands, one called SET NL and the other called CHANGE. The SET NL command is used above to indicate the total number of
primary load cases that the file contains. The CHANGE command will come in later (after the PERFORM ANALYSIS command).

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 0 3 12. 0. 0.</td>
</tr>
<tr>
<td>4 0 4.5 0 6 12. 4.5 0.</td>
</tr>
<tr>
<td>7 6. 9. 0. ; 8 12. 9. 0.</td>
</tr>
</tbody>
</table>

Joint number followed by X, Y and Z coordinates are provided above. Since this is a plane structure, the Z coordinates are given as all zeros.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 4 2 ; 3 5 7 ; 4 3 6 ; 5 6 8 ; 6 4 5 7</td>
</tr>
<tr>
<td>8 7 8 ; 9 1 5 ; 10 2 4 ; 11 3 5 ; 12 2 6</td>
</tr>
<tr>
<td>13 6 7 ; 14 5 8</td>
</tr>
</tbody>
</table>

Defines the members by the joints to which they are connected.

<table>
<thead>
<tr>
<th>MEMBER TRUSS</th>
</tr>
</thead>
<tbody>
<tr>
<td>9 TO 14</td>
</tr>
</tbody>
</table>

The preceding command defines that members 9 through 14 are of type truss. This means these members can only carry axial tension/compression and no moments.

<table>
<thead>
<tr>
<th>MEMBER PROP BRITISH</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 5 TABLE ST UB305X165X40</td>

<tr>
<td>6 7 8 TA ST UB457X152X52</td>
</tr>
<tr>
<td>9 TO 14 TA LD UA150X150X10</td>
</tr>
</tbody>
</table>

Properties for all members are assigned from the British steel table. The word ST stands for standard single section. The word LD stands for long leg back-to-back double angle. Since the spacing between the two angles of the double angle is not provided, it is assumed to be 0.0.

<table>

</tr>
<tr>
<td>END DEFINE MATERIAL</td>
</tr>
<tr>
<td>CONSTANTS</td>
</tr>
<tr>
<td>MATERIAL STEEL ALL</td>
</tr>
</tbody>
</table>

The DEFINE MATERIAL command is used to define a material. The CONSTANT command is used to assign this material all members. Length unit is changed from METER to MMS.

<table>
<thead>
<tr>
<th>SUPPORT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3 PINNED</td>
</tr>
</tbody>
</table>

Pinned supports are specified at Joints 1, 2 and 3. The word PINNED signifies that no moments will be carried by these supports.

| INACTIVE MEMBERS 9 TO 14 |
The preceding command makes the listed members inactive. The stiffness contribution of these members will not be considered in the analysis till they are made active again.

```
UNIT METER
LOADING 1 DEAD AND LIVE LOAD
```

Load case 1 is initiated followed by a title. The length UNIT is changed from MMS to METER for input values which follow.

```
MEMBER LOAD
6 8 UNI GY -4.5
7 UNI GY -6.75
```

Load 1 contains member loads. GY indicates that the load acts in the global Y direction. The word UNI stands for uniformly distributed load. The load is applied on members 6, 7, and 8.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis. It is worth noting that members 9 to 14 will not be used in this analysis since they were declared inactive earlier. In other words, for dead and live load, the bracing members are not used to carry any load.

```
CHANGES
```

The members inactivated earlier are restored using the CHANGE command.

```
INACTIVE MEMBERS 10 11 13
```

A new set of members are made inactive. The stiffness contribution from these members will not be used in the analysis till they are made active again. They have been inactivated to prevent them from being subject to compressive forces for the next load case.

```
LOADING 2 WIND FROM LEFT
```

Load case 2 is initiated followed by a title.

```
JOINT LOAD
4 FX 135 ; 7 FX 65
```

Load 2 contains joint loads. FX indicates that the load is a force in the global X direction. Nodes 4 and 7 are subjected to the loads.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis. The analysis will be performed for load case 2 only.

```
CHANGE
```

The above CHANGE command is an instruction to re-activate all inactive members.

```
INACTIVE MEMBERS 9 12 14
```

Members 9, 12 and 14 are made inactive. The stiffness contribution of these members will not be used in the analysis till they are made active again. They have been inactivated to prevent them from being subject to compressive forces for the next load case.

```
LOADING 3 WIND FROM RIGHT
```

Load case 3 is initiated followed by a title.

```
JOINT LOAD
6 FX -135 ; 8 FX -65
```
Load 3 contains joint loads at nodes 6 and 8. FX indicates that the load is a force in the global X direction. The negative numbers (-135 and -65) indicate that the load is acting along the negative global X direction.

<table>
<thead>
<tr>
<th>LOAD COMBINATION 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0.75 2 0.75</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>LOAD COMBINATION 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0.75 3 0.75</td>
</tr>
</tbody>
</table>

Load combination case 4 involves the algebraic summation of the results of load cases 1 and 2 after multiplying each by a factor of 0.75. For load combinations, the program simply gathers the results of the component primary cases, factors them appropriately, and combines them algebraically. Thus, an analysis in the real sense of the term (multiplying the inverted stiffness matrix by the load vector) is not carried out for load combination cases. Load combination case 5 combines the results of load cases 1 and 3.

**PERFORM ANALYSIS**

This command instructs the program to proceed with the analysis. Only primary load case 3 will be considered for this analysis. (As explained earlier, a combination case is not truly analyzed for, but handled using other means.)

**CHANGE**

The above **CHANGE** command will re-activate all inactive members.

**LOAD LIST ALL**

At the end of any analysis, only those load cases for which the analysis was done most recently, are recognized as the "active" load cases. The **LOAD LIST ALL** command enables all the load cases in the structure to be made active for further processing.

**PRINT MEMBER FORCES**

The preceding **PRINT** command is an instruction to produce a report, in the output file, of the member end forces.

**LOAD LIST 1 4 5**

A **LOAD LIST** command is a means of instructing the program to use only the listed load cases for further processing.

**PARAMETER**

<table>
<thead>
<tr>
<th>CODE</th>
<th>EN 1993-1-1:2005</th>
</tr>
</thead>
<tbody>
<tr>
<td>NA 1</td>
<td></td>
</tr>
<tr>
<td>BEAM</td>
<td>1 ALL</td>
</tr>
<tr>
<td>UNL</td>
<td>1.8 ALL</td>
</tr>
<tr>
<td>KY</td>
<td>0.5 ALL</td>
</tr>
</tbody>
</table>

The **PARAMETER** command is used to specify the steel design parameters (information on these parameters can be obtained from the manual where the implementation of the code is explained). The **BEAM** parameter is specified to perform design at every 1/12th point along the member length. **UNL** represents the unsupported length to be used for calculation of allowable bending stress. **KY 0.5 ALL** sets the effective length factor for column buckling about the local Y-axis to be 0.5 for ALL members.

**CHECK CODE ALL**

The above command instructs the program to perform a check to determine how you defined member sizes along with the latest analysis results meet the code requirements.

**FINISH**

This command terminates the STAAD run.

EX. UK-5 Support Settlement on a Portal Frame

This example demonstrates the application of support displacement load (also known as a sinking support) on a space frame structure.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-5 Support Settlement on a Portal Frame.STD when you install the program.

![Diagram of portal frame structure](image)

*Figure 487: Example Problem No. 5*

Where:

L1 = 3.0m  
L2 = 6.0m

Actual input is shown in bold lettering followed by explanation.

```
STAAD SPACE TEST FOR SUPPORT DISPLACEMENT
```

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

```
UNITS METER KNS
```

Defines the input units for the data that follows.

```
JOINT COORDINATES
1 0.0 0.0 0.0 ; 2 0.0 3.0 0.0
3 6.0 3.0 0.0 ; 4 6.0 0.0 0.0
5 6.0 3.0 6.0 ; 6 6.0 0.0 6.0
```

Joint number followed by X, Y and Z coordinates are provided above.
**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3</td>
</tr>
<tr>
<td>4 5 6</td>
</tr>
</tbody>
</table>

Defines the members by the joints to which they are connected.

<table>
<thead>
<tr>
<th>UNIT MMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMB PROP</td>
</tr>
<tr>
<td>1 TO 5 PRIS AX 6450 IZ 1.249E+08 IY 1.249E+08 IX 4.162E+06</td>
</tr>
</tbody>
</table>

Member properties have been defined above using the PRISMATIC attribute. Values of AX (area), IZ (moment of inertia about major axis), IY (moment of inertia about minor axis) and IX (torsional constant) are provided in MMS unit.

```
DEFINE MATERIAL START
ISOTROPIC STEEL
E 210.
POISSON 0.3
DENSITY 7.68191e-008
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 0.24821 FU 0.399894 RY 1.5 RT 1.2
END DEFINE MATERIAL
CONSTANTS
MATERIAL STEEL ALL
```

Material are defined using the DEFINE MATERIAL command and then assigned using the CONSTANT command.

<table>
<thead>
<tr>
<th>SUPPORT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 4 6 FIXED</td>
</tr>
</tbody>
</table>

Joints 1, 4 and 6 are fixed supports.

<table>
<thead>
<tr>
<th>LOAD</th>
<th>SUPPORT DISPLACEMENT LOAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 FY -15</td>
<td></td>
</tr>
</tbody>
</table>

Load 1 is a support displacement load which is also commonly known as a sinking support. FY signifies that the support settlement is in the global Y direction and the value of this settlement is 15mm downward.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis.

```
PRINT ANALYSIS RESULTS
```

The above PRINT command instructs the program to print joint displacements, support reactions and member forces.

```
FINISH
```

This command terminates the STAAD run.

STAAD.Pro 4686 User Manual
EX. UK-6 Prestress and Poststress Loading

This is an example of prestress loading in a plane frame structure.

It covers two situations:

1. From the member on which it is applied, the prestressing effect is transmitted to the rest of the structure through the connecting members (known in the program as PRESTRESS load).

2. The prestressing effect is experienced by the member(s) alone and not transmitted to the rest of the structure (known in the program as POSTSTRESS load).

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-6 Prestress and Poststress Loading.STD when you install the program.
Figure 488: Example Problem No. 6

Where:

- $L_1 = 4.5$ m
- $L_2 = 6$ m
- $L_3 = 12$ m

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE FRAME WITH PRESTRESSING LOAD**

Every input has to start with the term **STAAD**. The term **PLANE** signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

**UNIT METER KNS**

Defines the input units for the data that follows.

**JOINT COORD**

```
1 0. 0. ; 2 12. 0. ; 3 0. 6. ; 4 12. 6.
5 0. 10.5 ; 6 12. 10.5 ; 7 0. 15. ; 8 12. 15.
```

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

**Note**: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

**MEMBER INCIDENCE**

```
1 1 3 ; 2 3 5 ; 3 5 7 ; 4 2 4 ; 5 4 6
6 6 8 ; 7 3 4 ; 8 5 6 ; 9 7 8
```

| END DEFINE MATERIAL |
| CONSTANTS |
| MATERIAL CONCRETE ALL |

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members. Length unit is changed from METER to MMS to facilitate the input.

| LOADING 1 PRESTRESSING LOAD |
| MEMBER PRESTRESS |
| 7 8 FORCE 1350. ES 75. EM -300. EE 75. |

Load case 1 is initiated followed by a title. Load 1 contains PRESTRESS load. Members 7 and 8 have a cable force of 1350 KNs. The location of the cable at the start (ES) and end (EE) is 75 MMs above the centre of gravity while at the middle (EM) it is 300 MMs below the c.g. The assumptions and facts associated with this type of loading are explained in section 1 of the Technical Reference Manual.

| LOADING 2 POSTSTRESSING LOAD |
| MEMBER POSTSTRESS |
| 7 8 FORCE 1350. ES 75. EM -300. EE 75. |

Load case 2 is initiated followed by a title. Load 2 is a POSTSTRESS load. Members 7 and 8 have a cable force of 1350 KNs. The location of the cable is the same as in load case 1. For a difference between PRESTRESS loading and POSTSTRESS loading, as well as additional information about both types of loads, please refer to section 1 of the Technical Reference Manual.

| PERFORM ANALYSIS |

This command instructs the program to perform the analysis.

| UNIT METER |
| PRINT ANALYSIS RESULTS |

The preceding command is an instruction to write joint displacements, support reactions and member forces in the output file. The preceding line causes the results to be written in the length unit of meters.

| FINISH |

This command terminates the STAAD run.

EX. UK-7 Modeling Offset Connections in a Frame

This example illustrates modeling of structures with offset connections. Offset connections arise when the center lines of the connected members do not intersect at the connection point. The connection eccentricity behaves as a rigid link and is modeled through specification of MEMBER OFFSETS.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-7 Modeling Offset Connections in a Frame.STD when you install the program.

Figure 489: Example Problem No. 7
Application Examples
EX. British Design Examples

Where:

\[
L_1 = 4.5 \text{ m} \\
L_2 = 6 \text{ m} \\
L_3 = 178 \text{ mm} \\
L_4 = 152 \text{ mm}
\]

Actual input is shown in bold lettering followed by explanation.

### STAAD PLANE TEST FOR MEMBER OFFSETS

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

### UNIT METER KNS

Defines the input units for the data that follows.

<table>
<thead>
<tr>
<th>JOINT COORD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0. 0. ; 2 6. 0. ; 3 0. 4.5</td>
</tr>
<tr>
<td>4 6. 4.5 ; 5 0. 9. ; 6 6. 9.</td>
</tr>
</tbody>
</table>

Joint number followed by X and Y coordinates are provided above. Since this is a plane structure, the Z coordinates need not be provided.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

### SUPPORT

| 1 2 PINNED |

Pinned supports are specified at joints 1 and 2. The word PINNED signifies that no moments will be carried by these supports.

### MEMB INCI

<table>
<thead>
<tr>
<th>MEMB INCI</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 3 2 ; 3 3 5 4</td>
</tr>
<tr>
<td>5 3 4 ; 6 5 6 ; 7 1 4</td>
</tr>
</tbody>
</table>

Defines the members by the joints to which they are connected.

### MEMB PROP BRITISH

<table>
<thead>
<tr>
<th>MEMB PROP BRITISH</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 4 TABLE ST UC356X368X129</td>
</tr>
<tr>
<td>5 6 TA ST UB305X165X40</td>
</tr>
<tr>
<td>7 TA LD UA200X150X12</td>
</tr>
</tbody>
</table>

All member properties are from British steel table. The word ST stands for standard single section. LD stands for long leg back-to-back double angle.

The **DEFINE MATERIAL** command is used to specify material properties and the **CONSTANT** is used to assign the material to all members.

**LOADING 1 WIND LOAD**

Load case 1 is initiated followed by a title.

**JOINT LOAD**

\[ \begin{align*}
3 & \text{ FX 225.0} \\
5 & \text{ FX 112.5}
\end{align*} \]

Load 1 contains joint loads at nodes 3 and 5. FX indicates that the load is a force in the global X direction.

**PERFORM ANALYSIS**

The above command is an instruction to perform the analysis.

**UNIT METER**

**PRINT FORCES**

**PRINT REACTIONS**

The above PRINT commands are instructions for writing the member forces and support reactions to the output file. The preceding line causes the results to be written in the length unit of meters.

**FINISH**

This command terminates a STAAD run.

EX. UK-8 Concrete Design for a Space Frame

In this example, concrete design is performed on some members of a space frame structure. Design calculations consist of computation of reinforcement for beams and columns. Secondary moments on the columns are obtained through the means of a P-Delta analysis.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-8 Concrete Design for a Space Frame.STD when you install the program.

![Figure 490: Example Problem No. 8](image)

The above example represents a space frame, and the members are made of concrete. The input in the next page will show the dimensions of the members.

Two load cases, namely one for dead plus live load and another with dead, live and wind load, are considered in the design.
STAAD SPACE FRAME WITH CONCRETE DESIGN

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y and Z coordinates.

UNIT METER KNS

Defines the input units for the data that follows.

JOINT COORDINATE
1 0 0 0 ; 2 5.4 0 0 ; 3 11.4 0 0
4 0 0 7.2 ; 5 5.4 0 7.2 ; 6 11.4 0 7.2
7 0 3.6 0 ; 8 5.4 3.6 0 ; 9 11.4 3.6 0
10 0 3.6 7.2 ; 11 5.4 3.6 7.2 ; 12 11.4 3.6 7.2
13 5.4 7.2 0 ; 14 11.4 7.2 0 ; 15 5.4 7.2 7.2
16 11.4 7.2 7.2

Joint number followed by X, Y and Z coordinates are provided above.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCE
1 1 7 ; 2 4 10 ; 3 2 8 ; 4 8 13
5 5 11 ; 6 11 15 ; 7 3 9 ; 8 9 14
9 6 12 ; 10 12 16 ; 11 7 8 12
13 10 11 14 ; 15 13 14 ; 16 15 16
17 7 10 ; 18 8 11 ; 19 9 12
20 13 15 ; 21 14 16

Defines the members by the joints to which they are connected.

UNIT MMS
MEMB PROP
1 2 PRISMATIC YD 300.0 IZ 2.119E08 IY 2.119E08 –
IX 4.237E08
3 TO 10 PR YD 300.0 ZD 300.0 IZ 3.596E08 IY 3.596E08 –
IX 5.324E08
11 TO 21 PR YD 535.0 ZD 380 IZ 2.409E09 IY 1.229E09 –
IX 2.704E09

All member properties are provided using the PRISMATIC option. YD and ZD stand for depth and width. If ZD is not provided, a circular shape with diameter = YD is assumed for that cross section. All properties required for the analysis, such as, Area, Moments of Inertia, etc. are calculated automatically from these dimensions unless these are explicitly defined. For this particular example, moments of inertia (IZ, IY) and torsional constant (IX) are provided, so these will not be recalculated. The IX, IY, and IZ values provided in this example are only half the values of a full section to account for the fact that the full moments of inertia will not be effective due to cracking of concrete.

DEFINE MATERIAL START

END DEFINE MATERIAL
The DEFINE MATERIAL command is used to define material properties for concrete. The CONSTANT command is used to assign this to all members.

SUPPORT
1 TO 6 FIXED

Joints 1 to 6 are fixed supports.

LOAD 1 (1.4DL + 1.7LL)

Load case 1 is initiated followed by a title.

SELF Y -1.4

The selfweight of the structure is applied in the global Y direction with a -1.4 factor. Since global Y is vertically upward, the negative factor indicates that this load will act downwards.

MEMB LOAD
11 TO 16 UNI Y -42.0
11 TO 16 UNI Y -76.5

Load 1 contains member loads also. Y indicates that the load is in the local Y direction. The word UNI stands for uniformly distributed load.

LOAD 2 .75 (1.4DL + 1.7LL + 1.7WL)

Load case 2 is initiated followed by a title.

REPEAT LOAD
1 0.75

The preceding command will gather the load data values from load case 1, multiply them with a factor of 0.75 and utilize the resulting values in load 2.

JOINT LOAD
15 16 FZ 40.0
11 FZ 90.0
12 FZ 70.0
10 FZ 40.0

Load 2 contains some additional joint loads also. FZ indicates that the load is a force in the global Z direction.

PDELTA ANALYSIS

This command instructs the program to proceed with the analysis. The analysis type is P-DELTA indicating that second-order effects are to be calculated.

PRINT FORCES LIST 2 5 9 14 16

Member end forces are printed using the above PRINT commands. The LIST option restricts the print output to the members listed.

START CONCRETE DESIGN

The above command initiates a concrete design.

CODE BRITISH
TRACK 1.0 MEMB 14
TRACK 2.0 MEMB 16
MAXMAIN 40 ALL
The values for the concrete design parameters are defined in the above commands. Design is performed per the BS 8110 Code. The TRACK value dictates the extent of design related information provided in the output. MAXMAIN indicates that the maximum size of main reinforcement is the 40 mm bar. These parameters are described in the manual where British concrete design related information is available.

Details about additional assistance from Bentley and Partners can be found at program menu.
EX. UK-9 Modeling Slabs and Shear Walls Using Finite Elements

The space frame structure in this example consists of frame members and finite elements (plates). The finite element part is used to model floor slabs and a shear wall. Concrete design of an element is performed. This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-9 Modeling Slabs and Shear Walls Using Finite Elements.STD when you install the program.

Actual input is shown in bold lettering followed by explanation.

STAAD SPACE
* EXAMPLE PROBLEM WITH FRAME MEMBERS AND FINITE ELEMENTS

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The second line forms the title to identify this project.
The units for the data that follows are specified above.

```
JOINT COORD
  1 0 0 0 ; 2 0 0 6
  7 0 4.5 0 11 0 4.5 6
  12 1.5 4.5 0 14 4.5 4.5 0
  18 6 4.5 0 22 6 4.5 6
  23 7.5 4.5 0 25 10.5 4.5 0
  26 7.5 4.5 6 28 10.5 4.5 6
  29 12 4.5 0 33 12 4.5 6
  34 6 1.125 0 36 6 3.375 0
  37 6 1.125 6 39 6 3.375 6
```

The joint numbers and their coordinates are defined through the above set of commands. The automatic generation facility has been used several times in the above lines. See section 5.1.1 of the Technical Reference Manual (on page 2425) where the joint coordinate generation facilities are described.

```
MEMBER INCI
  *COLUMNS
    1 1 7 ; 2 2 11
    3 3 34 ; 4 34 35 ; 6 35 36 ; 10 36 18
    7 4 37 ; 8 37 38 ; 9 38 39 ; 10 39 22
    11 5 29 ; 12 6 33
  *BEAMS IN Z DIRECTION AT X=0
    13 7 8 16
  *BEAMS IN Z DIRECTION AT X=6.0
    17 18 19 20
  *BEAMS IN Z DIRECTION AT X=12.0
    21 29 30 24
  *BEAMS IN X DIRECTION AT Z = 0
    25 7 12 ; 26 12 13 ; 27 13 14 ; 28 14 18
    29 18 23 ; 30 23 24 ; 31 24 25 ; 32 25 29
  *BEAMS IN X DIRECTION AT Z = 12.0
    33 11 15 ; 34 15 16 ; 35 16 17 ; 36 17 22
    37 22 26 ; 38 26 27 ; 39 27 28 ; 40 28 33
```

The member incidences are defined through the above set of commands. For some members, the member number followed by the start and end joint numbers are defined. In other cases, STAAD's automatic generation facilities are utilized. Section 5 of the Technical Reference Manual describes these facilities in detail.

```
DEFINE MESH
  A JOINT 7
  B JOINT 11
  C JOINT 22
  D JOINT 18
  E JOINT 33
  F JOINT 29
  G JOINT 3
  H JOINT 4
```

The above lines define the nodes of super-elements. Super-elements are plate/shell surfaces from which a number of individual plate/shell elements can be generated. In this case, the points describe the outer corners of a slab and that of a shear wall. Our goal is to define the slab and the wall as several plate/shell elements.

```
GENERATE ELEMENT
  MESH ABCD 4 4
  MESH DCEF 4 4
  MESH DCHG 4 4
```
The above lines form the instructions to generate individual 4-noded elements from the super-element profiles. For example, the command MESH ABCD 4 4 means that STAAD.Pro has to generate 16 elements from the surface formed by the points A, B, C and D with 4 elements along the edges AB & CD and 4 elements along the edges BC & DA.

```
UNIT MMS
MEMB PROP
  1 TO 40 PRIS YD 300 ZD 300
```

Members 1 to 40 are defined as a rectangular prismatic section with 300 mm depth and 300 mm width.

```
ELEM PROP
  41 TO 88 TH 150
```

Elements 41 to 88 are defined to be 150 mm thick.

```
DEFINE MATERIAL START
  ISOTROPIC CONCRETE
  E 21.0
  POISSON 0.17
  DENSITY 2.36158e-008
  ALPHA 5e-006
  DAMP 0.05
  G 9.25
  TYPE CONCRETE
  STRENGTH FCU 0.0275
  END DEFINE MATERIAL
  CONSTANTS
  MATERIAL CONCRETE ALL
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
SUPPORT
  1 TO 6 FIXED
```

Joints 1 to 6 are defined as fixed supported.

```
UNIT KNS METER
LOAD 1 DEAD LOAD FROM FLOOR
  ELEMENT LOAD
    41 TO 72 PRESSURE -10.0
LOAD 2 WIND LOAD
  JOINT LOAD
    11 33 FZ -90.
    22 FZ -450.
```

Load 1 consists of a pressure load of 10 KNS/sq.m. The intensity on elements 41 to 72. The negative sign (and the default value for the axis) indicates that the load acts opposite to the positive direction of the element local z-axis.

```
LOAD 2 WIND LOAD
  JOINT LOAD
    11 33 FZ -90.
    22 FZ -450.
```

Load 2 consists of joint loads in the Z direction at joints 11, 22, and 33.

```
LOAD COMB 3
  1 0.9 2 1.3
```

Load 3 is a combination of 0.9 times load case 1 and 1.3 times load case 2.

```
PERFORM ANALYSIS
```
The command to perform an elastic analysis is specified above.

```
LOAD LIST 1 3
PRINT SUPP REAC
PRINT MEMBER FORCES LIST 27
PRINT ELEMENT STRESSES LIST 47
```

Support reactions, members forces and element stresses are printed for load cases 1 and 3.

```
START CONCRETE DESIGN
CODE BRITISH
DESIGN ELEMENT 47
END CONCRETE DESIGN
```

The above set of command form the instructions to STAAD to perform a concrete design on element 47. Design is done according to the British code. Note that design will consist only of flexural reinforcement calculations in the longitudinal and transverse directions of the elements for the moments MX and MY.

```
FINI
```

The STAAD run is terminated.

**User Manual**
EX. UK-10 Finite Element Model for a Rectangular Tank

A tank structure is modeled with four-noded plate elements. Water pressure from inside is used as loading for the tank. Reinforcement calculations have been done for some elements.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-10 Finite Element Model for a Rectangular Tank.STD when you install the program.
Figure 493: Deflected Shape

Actual input is shown in bold lettering followed by explanation.

STAAD SPACE FINITE ELEMENT MODEL OF TANK
* STRUCTURE

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame (3-D) structure.

UNITS METER KNS

Defines the input units for the data that follows.

JOINT COORDINATES
1 0. 0. 0. 5 0. 6. 0.
REPEAT 4 1.5. 0. 0.
REPEAT 4 0. 0. 1.5.
REPEAT 4 -1.5. 0. 0.
REPEAT 3 0. 0. -1.5.
81 1.5. 0. 1.5. 83 1.5. 0. 4.5.
REPEAT 2 1.5. 0. 0.

Joint number followed by X, Y and Z coordinates are provided above. The REPEAT command generates joint coordinates by repeating the pattern of the previous line of joint coordinates. The number following the REPEAT command is the number of repetitions to be carried out. This is followed by X, Y and Z coordinate increments. See section 5.11 of the Technical Reference Manual (on page 2425).

ELEMENT INCIDENCES
1 1 2 7 6 TO 4 1 1
REPEAT 14 4 5
61 76 77 2 1 TO 64 1 1
65 1 6 81 76
66 76 81 82 71
67 71 82 83 66
68 66 83 56 61
69 6 11 84 81
70 81 84 85 82
71 82 85 86 83
72 83 86 51 56
73 11 16 87 84
74 84 87 88 85
75 85 88 89 86
76 86 89 46 51
77 16 21 26 87
Element connectivities are input as above by providing the element number followed by joint numbers defining the element. The REPEAT command generates element incidences by repeating the pattern of the previous line of element nodes. The number following the REPEAT command is the number of repetitions to be carried out and that is followed by element and joint number increments. See section 5.12 of the Technical Reference Manual (on page 2428).

```
UNIT MMS
ELEMENT PROPERTIES
1 TO 80 TH 200.0
```

Element properties are provided by specifying that the elements are 200.0 mm THick.

```
DEFINE MATERIAL START
ISOTROPIC CONCRETE
  E 21.0
  POISSON 0.17
  DENSITY 2.4e-008
  ALPHA 5e-006
  DAMP 0.05
  G 9.25
  TYPE CONCRETE
  STRENGTH FCU 0.028
END DEFINE MATERIAL
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
SUPPORT
  1 TO 76 BY 5 81 TO 89 PINNED
```

Pinned supports are specified at the joints listed above. No moments will be carried by these supports. The expression 1 TO 76 BY 5 means 1, 6, 11, etc. up to 76.

```
UNIT METER
LOAD 1
  ELEMENT LOAD
  4 TO 64 BY 4 PR 50.0
  3 TO 63 BY 4 PR 100.0
  2 TO 62 BY 4 PR 150.0
  1 TO 61 BY 4 PR 200.0
```

Load case 1 is initiated. It consists of element loads in the form of uniform pressure (indicated by PR) acting along the local z-axis.

```
PERFORM ANALYSIS
```

This command instructs the program to proceed with the analysis.

```
UNIT MMS
  PRINT JOINT DISPLACEMENTS LIST 5 25 45 65
  PRINT ELEM FORCE LIST 9 TO 16
```
Joint displacements for a selected set of nodes and element corner forces for some elements are written in the output file as a result of the above commands. The forces printed are in the global directions at the nodes of the elements. The LIST option restricts the print output to that for the joints/elements listed.

```
START CONCRETE DESIGN
```

The above command initiates concrete design.

```
CODE BRITISH
DESIGN SLAB 9 12
```

Slabs (i.e., elements) 9 and 12 will be designed and the reinforcement requirements obtained. In STAAD, elements are typically designed for the moments MX and MY at the centroid of the element.

```
END CONCRETE DESIGN
```

Terminates the concrete design operation.

```
FINISH
```

This command terminates the STAAD run.

**END OF ELEMENT DESIGN**
EX. UK-11 Response Spectrum Analysis of a Frame

Dynamic analysis (Response Spectrum) is performed for a steel structure. Results of a static and dynamic analysis are combined. The combined results are then used for steel design.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-11 Response Spectrum Analysis of a Frame.STD when you install the program.

Where:

- \( L_1 = 3 \, \text{m} \), \( L_2 = 6 \, \text{m} \)
- \( w = 22.5 \, \text{kN/m} \)
- \( P_1 = 25 \, \text{kN} \), \( P_2 = 37.5 \, \text{kN} \)

Actual input is shown in bold lettering followed by explanation.

**STAAD PLANE RESPONSE SPECTRUM ANALYSIS**

Every input has to start with the term STAAD. The term PLANE signifies that the structure is a plane frame structure and the geometry is defined through X and Y axes.

**UNIT METER KNS**
Defines the input units for the data that follows.

```
JOINT COORDINATES
1 0.0 0.0 0.0 ; 2 6.0 0.0 0.0 
3 0.0 3.0 0.0 ; 4 6.0 3.0 0.0
5 0.0 6.0 0.0 ; 6 6.0 6.0 0.0
```

Joint number followed by X, Y and Z coordinates are provided above. Since this is a plane structure, the Z coordinates are all the same, in this case, zeros.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

```
MEMBER INCIDENCES
1 1 3 ; 2 2 4 ; 3 3 5 ; 4 4 6 
5 3 4 ; 6 5 6
```

Defines the members by the joints to which they are connected.

```
MEMBER PROPERTIES BRITISH
1 TO 4 TA ST UC254X254X73 
5 TA ST UB305X165X54 
6 TA ST UB203X133X30
```

Properties for all members are assigned from the British steel table. The word ST stands for standard single section.

```
SUPPORTS
1 2 FIXED
```

Fixed supports are specified at joints 1 and 2.

```
UNIT MMS
DEFINE MATERIAL START
ISOTROPIC STEEL
E 210
POISSON 0.3
DENSITY 7.6977e-008
ALPHA 6e-006
DAMP 0.03
TYPE STEEL
STRENGTH FY 0.24821 FU 0.399894 RY 1.5 RT 1.2
END DEFINE MATERIAL
CONSTANTS
MATERIAL STEEL ALL
```

Material constants such as E (modulus of elasticity), Poisson’s ratio and density (DEN) are specified above. Length unit is changed from METER to MMS to facilitate the input.

```
CUT OFF MODE SHAPE 2
```

The number of mode shapes to be considered in dynamic analysis is set to 2. Without the above command, this will be set to the default. [See section 5.30.1 of the Technical Reference Manual](on page 2539).

```
* LOAD 1 WILL BE STATIC LOAD
UNIT METER
LOAD 1 DEAD AND LIVE LOADS
SELFWEIGHT Y -1.0
```

Load case 1 is initiated followed by a title. Prior to this, the length unit is changed to METER for specifying distributed member loads. A line starting with an asterisk (*) mark indicates a comment line.
The above command indicates that the selfweight of the structure acting in the global Y direction is part of this load case. The factor of -1.0 is meant to indicate that the load acts opposite to the positive direction of global Y, hence downwards.

Load 1 contains member loads also. GY indicates that the load is in the global Y direction while Y indicates local Y direction. The word UNI stands for uniformly distributed load while CON stands for concentrated load. GY is followed by the value of the load and the distance at which it is applied.

The two lines which begin with the asterisk are comment lines which tell us the purpose of the next load case. Load case 2 is then initiated along with an optional title. This will be a dynamic load case. Permanent masses will be provided in the form of loads. These masses (in terms of loads) will be considered for the eigensolution. Internally, the program converts these loads to masses, hence it is best to specify them as absolute values (without a negative sign). Also, the direction (X, Y, Z etc.) of the loads will correspond to the dynamic degrees of freedom in which the masses are capable of vibrating. In a PLANE frame, only X and Y directions need to be considered. In a SPACE frame, masses (loads) should be provided in all three (X, Y and Z) directions if they are active along all three. The user has the freedom to restrict one or more directions.

The above commands indicate that the selfweight of the structure acting in the global X and Y directions with a factor of 1.0 is taken into consideration for the mass matrix.

The mass matrix will also consist of terms derived from the above member loads. GX and GY indicate that the load, and hence the resulting mass, is capable of vibration along the global X and Y directions. The word CON stands for concentrated load. Concentrated forces of 25, 37.5, and 25 kNs are located at 1.8m, 3.0m and 4.2m from the start of member 5.

The SPECTRUM command specifies a Eurocode 8 2004 seismic response spectrum load. The modal responses will be combined using the CQC method. Here, the spectrum effect is in the global X direction with a factor of 1.0. EC8 2004 response spectra are always given in terms of acceleration (ACC). A damping ratio of 0.05 (5%) is used. The second line then gives the soil type along with the alpha ratio and behavior factor, Q.
In a response spectrum analysis, the sign of the forces cannot be determined, and hence are absolute numbers. Consequently, to account for the fact that the force could be positive or negative, it is necessary to create 2 load combination cases. That is what is being done above. Load combination case no. 3 consists of the sum of the static load case (1) with the positive direction of the dynamic load case (2). Load combination case no. 4 consists of the sum of the static load case (1) with the negative direction of the dynamic load case (2). In both cases, the result is factored by 0.75.

**PERFORM ANALYSIS PRINT MODE SHAPES**

This command instructs the program to proceed with the analysis. The PRINT command instructs the program to print mode shape values.

**PRINT ANALYSIS RESULTS**

Displacements, reactions and member forces are recorded in the output file using the above command.

**LOAD LIST 1 3 4**
**PARAMETER**
**CODE EN 1993-1-1:2005**
**NA 1**
**SELECT ALL**

A steel design in the form of a member selection is performed based on the rules of the Eurocode 8 code using the UK national annex. Only the member forces resulting from load cases 1, 3 and 4 will be considered for these calculations.

**FINISH**

This command terminates the STAAD run.

Application Examples
EX. British Design Examples
EX. UK-12 Moving Load Generation on a Bridge Deck

This example demonstrates generation of load cases for the type of loading known as a moving load. This type of loading occurs classically when the load-causing units move on the structure, as in the case of trucks on a bridge deck. The mobile loads are discretized into several individual immobile load cases at discrete positions. During this process, enormous number of load cases may be created resulting in plenty of output to be sorted. To avoid looking into a lot of output, the maximum force envelope is requested for a few specific members.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-12 Moving Load Generation on a Bridge Deck.STD when you install the program.
Where:

\[ L_1 = 9 \text{ m} \]
\[ L_2 = 1.5 \text{ m} \]

Actual input is shown in bold lettering followed by explanation.

**STAAD FLOOR A SIMPLE BRIDGE DECK**

Every input has to start with the term STAAD. The word FLOOR signifies that the structure is a floor structure and the geometry is defined through X and Z axis.

**UNITS METER KNS**
Defines the input units for the data that follows.

**JOINT COORDINATES**

<table>
<thead>
<tr>
<th>Joint number followed by X, Y, and Z coordinates are provided above. Since this is a floor structure, the Y coordinates are all the same (in this case, zero). The first line generates joints 1 through 6. With the repeat (R) command, the coordinates of the next 30 joints are generated by repeating the pattern of the coordinates of the first 6 joints 5 times with X, Y and Z increments of 0, 0, and 9 respectively.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 6 7.5 0 0</td>
</tr>
<tr>
<td>R 5 0 0 9.0</td>
</tr>
</tbody>
</table>

**MEMBER INCIDENCES**

<table>
<thead>
<tr>
<th>Defines the members by the joints to which they are connected. The fourth number indicates the final member number up to which they will be generated. Repeat all (abbreviated as R A) will create members by repeating the member incidence pattern of the previous 11 members. The number of repetitions to be carried out is provided after the RA command and the member increment and joint increment are defined as 11 and 6 respectively. The fifth line of input defines the member incidences for members 56 to 60.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 7 6</td>
</tr>
<tr>
<td>7 1 2 11</td>
</tr>
<tr>
<td>R A 4 11 6</td>
</tr>
<tr>
<td>56 31 32 60</td>
</tr>
</tbody>
</table>

**MEMBER PROPERTIES BRITISH**

<table>
<thead>
<tr>
<th>Properties for all members are assigned from the British steel table. The word ST stands for standard single section.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 TO 60 TA ST UB305X165X40</td>
</tr>
</tbody>

**UNITS MMS**

<table>
<thead>
<tr>
<th>The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members. The units of length are changed from METER to MMS.</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIT METER KNS</td>
</tr>
</tbody>
</table>

The characteristics of the vehicle are defined above in METER and KNS units. The above lines represent the first out of two sets of data required in moving load generation. The type number (1) is a label for identification of the load-causing unit, such as a truck. Three axles (90 90 45) are specified with the LOAD command. The spacing between the axles in the direction of movement (longitudinal direction) is specified after the DISTANCE
command. WIDTH is the spacing in the transverse direction, that is, it is the distance between the 2 prongs of an axle of the truck.

LOAD 1

Load case 1 is initiated.

SELF Y -1.0

Selfweight of the structure acting in the negative (due to the factor -1.0) global Y direction is the only component of load case 1.

LOAD GENERATION 10
TYPE 1 2.25 0. 0. ZI 3.0

This constitutes the second of the two sets of data required for moving load generation. 10 load cases are generated using the Type 1 vehicle whose characteristics were described earlier. For the first of these load cases, the X, Y and Z location of the reference load (see section 5.31.1 of the Technical Reference Manual (on page 2541)) have been specified after the command TYPE 1. The Z Increment of 3.0m denotes that the vehicle moves along the Z direction and the individual positions which are 3.0m apart will be used to generate the remaining 9 load cases.

As seen in Section 5.31.1 of the Technical Reference manual, the reference wheel is on the last axle. The first load case which is generated will be the one for which the first axle is just about to enter the bridge. The last load case should be the one for which the last axle is just about to exit the bridge. Thus, the total distance travelled by the reference load will be the length of the vehicle (distance from first axle to last axle) plus the span of the bridge. In this problem, that comes to

\[(3.0+1.5) + 45 = 49.5 \text{ m} \]

This example uses 3.0 m increments and generates 10 load cases.

However, if you want the vehicle to move forward in 4.5 m increments (each 4.5 m increment will create a discrete position of the truck on the bridge), it would required \((49.5/4.5)+1 = 12\) cases to be generated.

PERFORM ANALYSIS PRINT LOAD

The above command instructs the program to proceed with the analysis and print the values and positions of all the generated load cases.

PRINT MAXFORCE ENVELOP LIST 3 41 42

A maximum force envelope consisting of the highest forces for each degree of freedom on the listed members will be written into the output file.

FINISH

This command terminates the STAAD run.

EX. UK-13 Section Displacements for a Frame

Calculation of displacements at intermediate points of members of a plane frame is demonstrated in this example.
This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-13 Section Displacements for a Frame.STD when you install the program.

![Diagram of Example Problem No. 13](image)

Figure 496: Example Problem No. 13

Where:

- $L_1 = 4.5 \text{ m}$, $L_2 = 6.0 \text{ m}$
- $P = 25 \text{ kN}$
- $w = 45 \text{ kN/m}$

The dashed line represents the deflected shape of the structure. The shape is generated on the basis of displacements at the ends plus several intermediate points of the members.

Actual input is shown in bold lettering followed by explanation.

```plaintext
STAAD PLANE TEST FOR SECTION DISPLACEMENT

UNIT METER KNS

JOINT COORDINATES
1 0 0 ; 2 0.4.5 ; 3 6 4.5 ; 4 6 0.

MEMBER INCIDENCE

EX. UK-14 P-Delta Analysis of a Frame Under Seismic Loads

A space frame is analyzed for seismic loads. The seismic loads are generated using the procedures of the building code. A P-Delta analysis is performed to obtain the secondary effects of the lateral and vertical loads acting simultaneously.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-14 P-Delta Analysis of a Frame Under Seismic Loads.STD when you install the program.
STAAD SPACE EXAMPLE PROBLEM FOR UBC LOAD

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame.

UNIT METER KNS

Defines the input units for the data that follows.

JOINT COORDINATES
1 0 0 4 10.5 0 0
REPEAT 3 0 0 3.5
REPEAT ALL 3 0 3.5 0

The X, Y and Z coordinates of the joints are specified here. First, coordinates of joints 1 through 4 are generated by taking advantage of the fact that they are equally spaced. Then, this pattern is REPEATED 3 times with a Z increment of 3.5 m for each repetition to generate joints 5 to 16. The REPEAT ALL command will then repeat 3 times, the pattern of joints 1 to 16 to generate joints 17 to 64.

MEMBER INCIDENCES
* beams in x direction
101 17 18 103
104 21 22 106
107 25 26 109

Figure 497: Example Problem No. 14
Defines the members by the joints to which they are connected. Following the specification of incidences for members 101 to 112, the REPEAT ALL command is used to repeat the pattern and generate incidences for members 113 through 136. A similar logic is used in specification of incidences of members 201 through 212 and generation of incidences for members 213 to 236. Finally, members incidences of columns 301 to 348 are specified.

The beam members have prismatic member property specification (YD & ZD) while the columns (members 301 to 348) have their properties called from the built-in British steel table.

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

**Tip:** You may see these values with the help of the command PRINT MATERIAL PROPERTIES following the preceding commands.
Indicates the joints where the supports are located as well as the type of support restraints.

```
DEFINE UBC LOAD
ZONE 0.2 I 1.0 RwX 9 RwZ 9 S 1.5 CT 0.032
SELFWEIGHT
JOINT WEIGHT
17 TO 48 WEIGHT 7.0
49 TO 64 WEIGHT 3.5
```

There are two stages in a static seismic load. The first stage is to define the code-specified load parameters along with the vertical loads (weights) from which the base shear will be calculated. The vertical loads may be specified in the form of selfweight, joint weights and/or member weights. Member weights are not shown in this example. It is important to note that these vertical loads are used purely in the determination of the horizontal base shear only. In other words, the structure is not analyzed for these vertical loads.

```
LOAD 1
UBC LOAD X 0.75
SELFWEIGHT Y -1.0
JOINT LOADS
17 TO 48 FY -7.0
49 TO 64 FY -3.5
```

This is the second stage in which the static seismic load is applied with the help of a load case number, corresponding direction (X in the above case) and a factor by which the generated horizontal loads should be multiplied. Along with the seismic lateral load, deadweight is also added to the same load case. Since we will be doing second-order (PDELTA) analysis, it is important that we include horizontal and vertical loads in the same load case.

```
LOAD 2
UBC LOAD Z 0.75
SELFWEIGHT Y -1.0
JOINT LOADS
17 TO 48 FY -7.0
49 TO 64 FY -3.5
```

In load case 2, the static seismic load is being applied in the Z direction. Vertical loads are part of this case, also.

```
PDELTA ANALYSIS PRINT LOAD DATA
```

We are requesting a second-order analysis by specifying the command `PDELTA ANALYSIS. PRINT LOAD DATA` is used to obtain a report of all the applied and generated loadings.

```
PRINT SUPPORT REACTIONS
FINISH
```

The above commands are self-explanatory.

************** END OF LATEST ANALYSIS RESULT **************

**70. FINISH**

**EX. UK-15 Wind and Floor Load Generation on a Space Frame**

A space frame is analyzed for loads generated using the built-in wind and floor load generation facilities.
This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-15 Wind and Floor Load Generation on a Space Frame.STD when you install the program.

STAAD SPACE - WIND AND FLOOR LOAD GENERATION

This is a space frame analysis problem. Every STAAD input has to start with the command STAAD. The SPACE specification is used to denote a space (3D) frame.

UNIT METER KNS

The UNIT specification is used to specify the length and/or force units to be used.

JOINT COORDINATES
1 0 0 0
2 4 0 0
3 9 0 0
4 0 0 4
5 4 0 4
6 0 0 8
7 4 0 8
8 9 0 8
REPEAT ALL 2 0 3.5 0
The JOINT COORDINATE specification is used to specify the X, Y, and Z coordinates of the joints. Note that the REPEAT ALL command has been used to generate joints for the two upper stories each with a Y increment of 3.5 m.

UNIT METER

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

SUPPORT
1 TO 8 FIXED BUT MX MZ

The supports of the structure are defined through the SUPPORT specification. Here all the supports are FIXED with releases specified in the MX (rotation about global X-axis) and MZ (rotation about global Z-axis) directions.

DEFINE WIND LOAD
TYPE 1
  INTENSITY 1.0 1.5 HEIGHT 3.5 7.0
  EXPOSURE 0.90 YRANGE 6.0 8.0
  EXPOSURE 0.85 JOINT 9 12 14

When a structure has to be analyzed for wind loading, the engineer is confronted with the task of first converting an abstract quantity like wind velocity or wind pressure into concentrated loads at joints, distributed loads on members, or pressure loads on plates. The large number of calculations involved in this conversion can be
avoided by making use of STAAD's wind load generation utility. This utility takes wind pressure at various
heights as the input, and converts them to values that can then be used as concentrated forces known as joint
loads in specific load cases. The input specification is done in two stages. The first stage is initiated above
through the DEFINE WIND LOAD command. The basic parameters of the WIND loading are specified here. All
values need to be provided in the current UNIT system. Each wind category is identified with a TYPE number (an
identification mark) which is used later to specify load cases.

In this example, two different wind intensities (1.0 KN/sq. m and 1.5 KN/sq. m) are specified for two different
height zones (0 to 3.5 m and 3.5 to 7.0 m). The EXPOSURE specification is used to mitigate or magnify the effect at
specific nodes due to special considerations like openings in the structure. In this case, two different exposure
factors are specified. The first EXPOSURE specification specifies the exposure factor as 0.9 for all joints within
the height range (defined as global Y-range) of 6.0m – 8.0m. The second EXPOSURE specification specifies the
exposure factor as 0.85 for joints 9, 12 and 14. In the EXPOSURE factor specification, the joints may be specified
directly or through a vertical range specification.

LOAD 1 WIND LOAD IN X-DIRECTION
WIND LOAD X 1.2 TYPE 1

This is the second stage of input specification for the wind load generation. The term WIND LOAD and the
direction term that follows are used to specify the wind loading in a particular lateral direction. In this case,
WIND loading TYPE 1, defined previously, is being applied in the global X-direction with a positive
multiplication factor of 1.2.

LOAD 2 FLOOR LOAD @ Y = 3.5M AND 7M
FLOOR LOAD
YRANGE 3.4 3.6 FLOAD -5.0 XRANGE 0.0 4.0 ZRANGE 0.0 8.0
YRANGE 3.4 3.6 FLOAD -2.5 XRANGE 4.0 9.0 ZRANGE 0.0 8.0
YRANGE 6.9 7.1 FLOAD -2.5

In load case 2 in this problem, a floor load generation is performed. In a floor load generation, a pressure load
(force per unit area) is converted by the program into specific points forces and distributed forces on the
members located in that region. The YRANGE, XRANGE, and ZRANGE specifications are used to define the area of
the structure on which the pressure is acting. The FLOAD specification is used to specify the value of that
pressure. All values need to be provided in the current UNIT system. For example, in the first line in the above
FLOOR LOAD specification, the region is defined as being located within the bounds YRANGE of 3.4 – 3.6 m,
XRANGE of 0.0 - 4.0 m and ZRANGE of 0.0 - 8.0 m. The -5.0 signifies that the pressure is 5.0 KN/sq.m. in the
negative global Y direction.

The program will identify the members lying within the specified region and derive member loads on these
members based on two-way load distribution.

PERFORM ANALYSIS PRINT LOAD DATA

We can view the values and position of the generated loads with the help of the PRINT LOAD DATA command
used above along with the PERFORM ANALYSIS command.

PRINT SUPPORT REACTION
FINISH

Above commands are self-explanatory.

EX. UK-16 Time History Analysis for Forcing Function and Ground Motion

Dynamic Analysis (Time History) is performed for a 3 span beam with concentrated and distributed masses. The structure is subjected to “forcing function” and “ground motion” loading. The maxima of joint displacements, member end forces and support reactions are determined.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-16 Time History Analysis for Forcing Function and Ground Motion.STD when you install the program.
Figure 499: Example Problem No. 16

Where:

L1 = 1.2 m

STAAD PLANE EXAMPLE FOR TIME HISTORY ANALYSIS

Every input file has to start with the word STAAD. The term PLANE signifies that the structure is a plane frame.

UNITS CMS KNS

Specifies the units to be used.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  0.0  0.0  0.0</td>
</tr>
<tr>
<td>2  0.0 120.0  0.0</td>
</tr>
<tr>
<td>3  0.0 240.0  0.0</td>
</tr>
<tr>
<td>4  0.0 360.0  0.0</td>
</tr>
</tbody>
</table>

Joint number followed by the X, Y and Z coordinates are specified above.

<table>
<thead>
<tr>
<th>MEMBER INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 2 3</td>
</tr>
</tbody>
</table>

Incidences of members 1 to 3 are specified above.

<table>
<thead>
<tr>
<th>MEMBER PROPERTIES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3 PRIS AX 100.0 IZ 833.33</td>
</tr>
</tbody>
</table>
All the members have PRISMATIC property specification. Since this is a plane frame, Area of cross section (AX) and Moment of Inertia (IZ) about the Z axis are adequate for the analysis.

SUPPORTS 1 4 PINNED

Pinned supports are located at nodes 1 and 4.

DEFINE MATERIAL ISOTROPIC CONCRETE
E 2850
POISSON 0.17
DENSITY 25e-006
ALPHA 5e-006
DAMP 0.05
G 925
TYPE CONCRETE
STRENGTH FCU 2.75
END DEFINE MATERIAL

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

The following are the constants used:

UNIT NEWTON METER
DEFINE TIME HISTORY
TYPE 1 FORCE
0.0 -20.0 0.5 100.0 1.0 200.0 1.5 500.0 2.0 800.0 2.5 500.0 3.0 70.0
TYPE 2 ACCELERATION
0.0 0.1 0.5 -0.25 1.0 -0.5 1.5 -0.9 2.0 -1.3 2.5 -1.0 3.0 -0.7
ARRIVAL TIMES
0.0
DAMPING 0.075

There are two stages in the command specification required for a time history analysis. The first stage is defined above. First the characteristics of the time varying load are provided. The loading type may be a forcing function (vibrating machinery) or ground motion (earthquake). The former is input in the form of time-force pairs while the latter is in the form of time-acceleration pairs. Following this data, all possible arrival times for these loads on the structure as well as the modal damping ratio are specified. In this example, the damping ratio is the same (7.5%) for all modes.

LOAD 1 STATIC LOAD
MEMBER LOAD
1 2 3 UNI GX 500.0

Load case 1 above is a static load. A uniformly distributed force of 500 Newton/m acts along the global X direction on all 3 members.

LOAD 2 TIME HISTORY LOAD
SELFWEIGHT X 1.0
SELFWEIGHT Y 1.0
JOINT LOAD
2 3 FX 4000.0
TIME LOAD
2 3 FX 1 1
GROUND MOTION X 2 1

This is the second stage in the command specification for time history analysis. This involves the application of the time varying load on the structure. The masses that constitute the mass matrix of the structure are specified.
through the selfweight and joint load commands. The program will extract the lumped masses from these weights. Following that, both the TIME LOAD and GROUND MOTION are applied simultaneously.

**Note:** This example is only for illustration purposes and that it may be unlikely that a TIME LOAD and GROUND MOTION both act on the structure at the same time.

The Time load command is used to apply the Type 1 force, acting in the global X direction, at arrival time number 1, at nodes 2 and 3. The Ground motion, namely, the Type 2 time history loading, is also in the global X direction at arrival time 1.

PERFORM ANALYSIS

The above command initiates the analysis process.

PRINT JOINT DISPLACEMENTS

During the analysis, the program calculates joint displacements for every time step. The absolute maximum value of the displacement for every joint is then extracted from this joint displacement history. So, the value printed using the above command is the absolute maximum value for each of the six degrees of freedom at each node.

UNIT KNS METER
PRINT MEMBER FORCES
PRINT SUPPORT REACTION

The member forces and support reactions too are calculated for every time step. For each degree of freedom, the maximum value of the member force and support reaction is extracted from these histories and reported in the output file using the above command.

The above set of data is used to provide joint coordinates for the various joints of the structure. The Cartesian system is being used here. The data consists of the joint number followed by global X and Y coordinates. Note that for a space frame, the Z coordinate(s) need to be provided also.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

The above data set contains the member incidence information or the joint connectivity data for each member. This completes the geometry of the structure.

START USER TABLE

This command is utilized to set up a user-provided steel table. All user-provided steel tables must start with this command.

TABLE 1

Each table needs an unique numerical identification. The above command starts setting up Table no. 1. Up to twenty tables may be specified per run.

UNIT CM
WIDE FLANGE

This command is used to specify the section-type as WIDE FLANGE in this table. Note that several section-types such as WIDE FLANGE, CHANNEL, ANGLE, TEE etc. are available for specification (See section 5.19 of the Technical Reference Manual (on page 2446)).

<table>

</tr>
</tbody>
</table>

The above data set is used to specify the properties of three wide flange sections. The data for each section consists of two parts. In the first line, the section-name is provided. You are allowed to provide any section name within twelve characters. The second line contains the section properties required for the particular section-type. Each section-type requires a certain number of data (area of cross-section, depth, moment of inertias etc.) provided in a certain order. For example, in this case, for wide flanges, ten different properties are required.

TABLE 2
UNIT CM
ANGLES
L30305 | 3.0 3.0 0.5 0.58 1.0 1.0 |
L40405 |
The above command and data lines set up another user provided table consisting of angle sections.

**END**

This command signifies the end of the user provided table data set. All user provided table related input must be terminated with this command.

**MEMBER PROPERTIES**

1 3 4 UPT 1 BEAM350
2 UPT 1 BEAM300 ; 5 6 7 UPT 1 BEAM250
8 TO 13 UPT 1 BEAM250
14 TO 19 UPT 2 L30305
20 TO 23 UPT 2 L40405

In the above command lines, the member properties are being assigned from the user provided tables created earlier. The word UPT signifies that the properties are from the user-provided table. This is followed by the table number and then the section name as specified in the user-provided table. The numbers 1 or 2 following the word UPT indicate the table from which section names are fetched.

**MEMBER TRUSS**

14 TO 23

The above command is used to designate members 14 to 23 as truss members.

**MEMBER RELEASE**

5 START MZ

The MEMBER RELEASE command is used to release the MZ moment at the start joint of member no. 5.

**UNIT MMS**

**DEFINE MATERIAL START**

ISOTROPIC STEEL

CONSTANTS
MATERIAL STEEL ALL
BETA 90.0 MEMB 3 4

The above command set is used to specify modulus of elasticity, density, Poisson’s ratio and beta angle values. Built-in default value of steel is used for the material constants.

**UNIT KNS METER**

The force unit is reset to KNS, and length unit to METER using this command.

**SUPPORT**

1 FIXED ; 2 PINNED

The above command set is used to designate supports. Here, joint 1 is designated as a fixed support and joint 2 is designated as a pinned support.

**LOADING 1 DEAD AND LIVE LOAD**

SELFWEIGHT Y -1.0
The above command set is used to specify the loadings on the structure. In this case, dead and live loads are provided through load case 1. It consists of selfweight, concentrated loads at joints 4, 5 and 11, and distributed loads on some members.

This command instructs the program to execute the analysis at this point.

The above commands are used to specify parameters for steel design.

This command will perform a code check on members 3 and 19 per the Eurocode 3 steel design code with the UK National Annex. A member selection too is performed for member 20. For each member, the member selection will be performed from the table that was originally used for the specification of the member property. In this case, the selection will be from the respective user tables from which the properties were initially assigned. It may be noted that properties may be provided (and selection may be performed) from built-in steel tables and user provided tables in the same data file.

This command terminates a STAAD run.

**EX. UK-18 Stress Calculation for Plate Elements**

This is an example which demonstrates the calculation of principal stresses on a finite element.

This problem is installed with the program by default to
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-18
Stress Calculation for Plate Elements.STD when you install the program.
Where:

$L = 3 \text{ m}$

Fixed Supports at Joints 1, 2, 3, 4, 5, 9, 13

Load intensity = 2000 Kn/sq.m in -Y direction

Actual input is shown in bold lettering followed by explanation.

STAAD SPACE SAMPLE CALCULATION FOR
* ELEMENT STRESSES

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame (3-D structure).

UNIT METER KNS

Defines the input units for the data that follows.

JOINT COORDINATES
1 0 0 4 9 0 0
REPEAT 3 0 0 3

Joint number followed by X, Y and Z coordinates are provided above. The REPEAT command is used to generate coordinates of joints 5 to 16 based on the pattern of joints 1 to 4.

ELEMENT INCIDENCE
1 1 5 6 2 TO 3
REPEAT 2 3 4
Element connectivities of elements 1 to 3 are defined first, based on which, the connectivities of elements 4 to 9 are generated.

```plaintext
ELEMENT PROPERTIES
1 TO 9 THICK 0.25
```

Elements 1 to 9 have a thickness of 0.25 m.

```plaintext
UNIT MMS
DEFINE MATERIAL ISOTROPIC CONCRETE E 21.0 POISSON 0.17 DENSITY 2.36158e-008 ALPHA 5e-006 DAMP 0.05 G 9.25 TYPE CONCRETE STRENGTH FCU 0.0275 END DEFINE MATERIAL CONSTANTS MATERIAL CONCRETE ALL UNIT METER
```

The `DEFINE MATERIAL` command is used to specify material properties and the `CONSTANT` is used to assign the material to all members.

```plaintext
SUPPORT 1 TO 4 5 9 13 FIXED
```

Fixed support conditions exist at the above mentioned joints.

```plaintext
LOAD 1 ELEMENT LOAD 1 TO 9 PRESSURE -2000.0
```

A uniform pressure of 2000 Kn/sq.m is applied on all the elements. In the absence of an explicit direction specification, the load is assumed to act along the local Z axis. The negative value indicates that the load acts opposite to the positive direction of the local Z.

```plaintext
PERFORM ANALYSIS
```

The above command instructs the program to proceed with the analysis.

```plaintext
PRINT SUPPORT REACTION
```

The above command is self-explanatory.

```plaintext
UNIT MMS PRINT ELEMENT STRESSES LIST 4
```

Element stresses at the centroid of the element are printed using the above command. The output includes membrane stresses, shear stresses, bending moments per unit width and principal stresses. The change of length unit from meter to mms indicates that the values will be printed in KN and MMs units.

```plaintext
FINISH
```

The STAAD run is terminated.

**Calculation of principal stresses for element 4**

Calculations are presented for the top surface only.
\[ SX = 0.0 \text{kN/mm}^2 \]
\[ SY = 0.0 \text{kN/mm}^2 \]
\[ SXY = 0.0 \text{kN/mm}^2 \]
\[ MX = 2,111.84 \text{kN-mm/mm} \]
\[ MY = 10,726.22 \text{kN-mm/m} \]
\[ MXY = 4,553.97 \text{kN-mm/mm} \]
\[ S = \frac{1}{6t^2} = \frac{1}{(6 \cdot 250^2)} = 10,416.67 \text{mm}^2 \] (Section Modulus)
\[ \sigma_x = SX + \frac{MX}{S} = 0.0 + \frac{2,111.84}{10,416.67} = 0.2027 \text{kN/mm} \]
\[ \sigma_y = SY + \frac{MY}{S} = 0.0 + \frac{10,726.22}{10,416.67} = 1.0297 \text{kN/mm} \]
\[ \tau_{xy} = SXY + \frac{MXY}{S} = 0.0 + \frac{4,553.97}{10,416.67} = 0.4372 \text{kN/mm} \]
\[ T_{Max} = \sqrt{\frac{(\sigma_x - \sigma_y)^2}{4} + \tau_{xy}^2} = \sqrt{\frac{(0.2027 - 1.0297)^2}{4} + 0.4372^2} = 0.6018 \text{KN/mm}^2 \]
\[ S_{Max} = \frac{(\sigma_x + \sigma_y)}{2} + T_{Max} = (0.2027 + 1.0297)/2 + 0.6018 = 1.218 \text{kN/mm}^2 \]
Say 1.22 kN/mm²
\[ S_{Min} = \frac{(\sigma_x + \sigma_y)}{2} - T_{Max} = (0.2027 + 1.0297)/2 - 0.6018 = 0.0144 \text{kN/mm}^2 \]
Say 0.01 kN/mm²

\[ \text{Angle} = \frac{1}{2} \tan^{-1}\left(\frac{2\tau_{xy}}{\sigma_x - \sigma_y}\right) = \frac{1}{2} \tan^{-1}\left(\frac{2(0.4372)}{0.2027 - 1.0297}\right) = -23.30^\circ \]
\[ \text{VON} = 0.707\sqrt{(S_{Max} - S_{Min})^2 + S_{Max}^2 + S_{Min}^2} = 0.707\sqrt{(1.218 - 0.0144)^2 + 1.218^2 + 0.0144^2} = 1.2107 \text{kN/mm}^2 \]

EX. UK-19 Inclined Supports

This example demonstrates the usage of inclined supports. The word INCLINED refers to the fact that the restraints at a joint where such a support is specified are along a user-specified axis system instead of along the default directions of the global axis system. STAAD.Pro offers a few different methods for assigning inclined supports, and we examine those in this example.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-19 Inclined Supports.STD when you install the program.

![Figure 502: Example Problem No. 19](image)

Actual input is shown in bold lettering followed by explanation.

```
STAAD SPACE
INPUT WIDTH 79
```

Every input has to start with the term STAAD. The word SPACE signifies that the structure is a space frame structure (3-D) and the geometry is defined through X, Y, and Z coordinates.

```
UNIT METER KN
```

Defines the input units for the data that follows.

```
JOINT COORDINATES
1 0 5 0; 2 10 5 10; 3 20 5 20; 4 30 5 30; 5 5 0 5; 6 25 0 25;
```

Joint number followed by X, Y and Z coordinates are provided above.

**Note:** Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.
Defines the members by the joints to which they are connected.

```
UNIT MMS KN
MEMBER PROPERTY AMERICAN
 4 5 PRIS YD 800
 1 TO 3 PRIS YD 750 ZD 500
```

Properties for all members of the model are provided using the PRISMATIC option (abbreviated to PRIS here). YD and ZD stand for depth and width. If ZD is not provided, a circular shape with diameter = YD is assumed for that cross section. All properties required for the analysis, such as, Area, Moments of Inertia, etc. are calculated automatically from these dimensions unless these are explicitly defined. The values are provided in MMS unit.

```

  6 INCLINED REFJT 3 FIXED BUT MX MY MZ KFX 30000
  1 PINNED
  4 INCLINED 1 0 1 FIXED BUT FX MX MY MZ
```

We assign supports (restraints) at 4 nodes - 5, 6, 1 and 4. For 3 of those, namely, 5, 6 and 4, the node number is followed by the keyword INCLINED, signifying that an INCLINED support is defined there. For the remaining one - node 1 - that keyword is missing. Hence, the support at node 1 is a global direction support.

The most important aspect of inclined supports is their axis system. Each node where an inclined support is defined has its own distinct local X, local Y and local Z axes. In order to define the axis system, we first have to define a datum point. The support node and the datum point together help define the axis system.

Three different methods are shown in the above 3 instances for defining the datum point.

- At node 5, notice the keyword REF followed by the numbers (10,5,10). This means that the datum point associated with node 5 is one which has the global coordinates of (10m, 5m, 10m). Coincidentally, this happens to be node 2.
- At node 6, the keyword REFJT is used followed by the number 3. This means that the datum point for support node 6 is the joint number 3 of the model. The coordinates of the datum point are hence those of node 3, namely, (20m, 5m and 20m).
- At node 4, the word INCLINED is merely followed by 3 numbers (1,0,1). In the absence of the words REF and REFJT, the program sets the datum point to be the following. It takes the coordinates of node 4, which are (30m,5m,30m) and adds to them, the 3 numbers which comes after the word INCLINED. Thus, the datum point becomes (31m, 5m and 31m).
Once the datum point is established, the local axis system is defined as follows. Local X is a straight line (vector) pointing from the support node towards the datum point. Local Z is the vector obtained by the cross product of local X and the global Y axis (unless the SET Z UP command is used in which case one would use global Z instead of global Y and that would yield local Y). Local Y is the vector resulting from the cross product of local Z and local X. The right hand rule must be used when performing these cross products.

Notice the unique nature of these datum points. The one for node 5 tells us that a line connecting nodes 5 to 2 is the local X axis, and is hence along the axis of member 4. By defining a KFX spring at that one, we are saying that the lower end of member 4 can move along its axis like the piston of a car engine. Think of a pile bored into rock with a certain amount of freedom to expand and contract axially.

The same is true for the support at the bottom of member 5. The local X axis of that support is along the axis of member 5. That also happens to be the case for the supported end of member 3. The line going from node 4 to the datum point (31,5,31) happens to be coincident with the axis of the member, or the traffic direction. The expression FIXED BUT FX MX MY MZ for that support indicates that it is free to translate along local X, suggesting that it is an expansion joint - free to expand or contract along the axis of member 3.

Since MX, MY, and MZ are all released at these supports, no moment will be resisted by these supports.

LOAD COMB 3
1 1.0 2 1.0
PERFORM ANALYSIS PRINT STATICS CHECK

Three load cases followed by the instruction for the type of analysis are specified. The PRINT STATICS CHECK option will instruct the program to produce a report consisting of total applied load versus total reactions from the supports for each primary load case.

PRINT SUPPORT REACTION

By default, support reactions are printed in the global axis directions. The above command is an instruction for such a report.

SET INCLINED REACTION
PRINT SUPPORT REACTION

Just earlier, we saw how to obtain support reactions in the global axis system. What if we need them in the inclined axis system? The "SET INCLINED REACTION" is a switch for that purpose. It tells the program that reactions should be reported in the inclined axis system instead of the global axis system. This has to be followed by the PRINT SUPPORT REACTIONS command.

PRINT MEMBER FORCES
PRINT JOINT DISP
FINISH

Member forces are reported in the local axis system of the members. Joint displacements at all joints are reported in the global axis system. Following this, the STAAD run is terminated.

EX. UK-20 Generating a Structure in Cylindrical Coordinates

This example generates the geometry of a cylindrical tank structure using the cylindrical coordinate system. The tank lies on its side in this example.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-20 Generating a Structure in Cylindrical Coordinates.STD when you install the program.

In this example, a cylindrical tank is modeled using finite elements. The radial direction is in the XY plane and longitudinal direction is along the Z-axis. Hence, the coordinates in the XY plane are generated using the cylindrical coordinate system.

STAAD SPACE

UNIT METER KN

The type of structure (space frame) and length and force units for data to follow are specified.

JOINT COORD CYLINDRICAL

The above command instructs the program that the coordinate data that follows is in the cylindrical coordinate system (r,theta,z).

1 3.5 0 0 8 3.5 315 0

Joint 1 has an 'r' of 3.5 meters, theta of 0 degrees and Z of 0 ft. Joint 8 has an 'r' of 3.5 meters, theta of 315 degrees and Z of 0 ft. The 315 degrees angle is measured counter-clockwise from the +ve direction of the X-axis. Joints 2 to 7 are generated by equal increments of the coordinate values between joints 1 and 8.

REPEAT 2 0 0 3.0
The REPEAT command is used to generate joints 9 through 24 by repeating twice, the pattern of joints 1 to 8 at Z-increments of 3.0 meters for each REPEAT.

<table>
<thead>
<tr>
<th>PRINT JOINT COORD</th>
</tr>
</thead>
</table>

The above command is used to produce a report consisting of the coordinates of all the joints in the Cartesian coordinate system. Note that even though the input data was in the cylindrical coordinate system, the output is in the Cartesian coordinate system.

<table>
<thead>
<tr>
<th>ELEMENT INCIDENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 2 10 9 TO 7 1 1</td>
</tr>
<tr>
<td>8 8 1 9 16</td>
</tr>
<tr>
<td>REPEAT ALL 1 8 8</td>
</tr>
</tbody>
</table>

The above 4 lines identify the element incidences of all 16 elements. Incidences of element 1 is defined as 1 2 10 9. Incidences of element 2 is generated by incrementing the joint numbers of element 1 by 1, incidences of element 3 is generated by incrementing the incidences of element 2 by 1 and so on up to element 7. Incidences of element 8 has been defined above as 8 1 9 16. The REPEAT ALL command states that the pattern of all the elements defined by the previous 2 lines, namely elements 1 to 8, must be repeated once with an element number increment of 8 and a joint number increment of 8 to generate elements 9 through 16.

<table>
<thead>
<tr>
<th>PRINT ELEMENT INFO</th>
</tr>
</thead>
</table>

The above command is self-explanatory.

EX. UK-21 Analysis of a Structure with Tension-Only Members

This example illustrates the modeling of tension-only members using the MEMBER TENSION command.
This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-21 Analysis of a Structure with Tension-Only Members.STD when you install the program.

It is important to note that the analysis can be done for only 1 load case at a time. This is because, the set of “active” members (and hence the stiffness matrix) is load case dependent.

![Figure 504: Example Problem No. 21](image)

where:

\[ L = 5.25 \text{ m}, \; H = 3.5 \text{ m} \]

Load case 1: \( P_1 = 45 \text{ kN} \) & \( P_2 = 70 \text{ kN} \)
Load case 2: \( P_3 = -45 \text{ kN} \) & \( P_4 = -70 \text{ kN} \)

**STAAD PLANE EXAMPLE FOR TENSION-ONLY MEMBERS**

The input data is initiated with the word STAAD. This structure is a PLANE frame.

**UNIT METER KNS**

Units for the commands to follow are defined above.

**JOINT COORDINATES**

1 0 0 ; 2 0 3.5 ; 3 0 7.0 ; 4 5.25 7.0 ; 5 5.25 3.5 ; 6 5.25 0
Joint coordinates of joints 1 to 6 are defined above.

```
MEMBER INCIDENCES
1 1 2 5
6 1 5 ; 7 2 6 ; 8 2 4 ; 9 3 5 ; 10 2 5
```

Incidences of members 1 to 10 are defined.

```
MEMBER TENSION
6 TO 9
```

Members 6 to 9 are defined as tension-only members using the MEMBER TENSION command. Hence for each load case, if during the analysis, any of the members 6 to 9 is found to be carrying a compressive force, it is disabled from the structure and the analysis is carried out again with the modified structure.

```
MEMBER PROPERTY BRITISH
1 TO 10 TA ST UC152X152X30
```

All members have been assigned a UC section from the British table.

```
UNIT MMS
DEFINE MATERIAL START

User Manual
EX. UK-22 Time History Analysis for Sinusoidal Loading

A space frame structure is subjected to a sinusoidal (dynamic) loading. The commands necessary to describe the sine function are demonstrated in this example. Time History analysis is performed on this model.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-22 Time History Analysis for Sinusoidal Loading.STD when you install the program.
STAAD SPACE
*EXAMPLE FOR HARMONIC LOADING GENERATOR

Every STAAD input file has to begin with the word STAAD.
The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. The comment line which begins with an asterisk is an optional title to identify this project.

UNIT KNS METER

The units for the data that follows are specified above.

JOINT COORDINATES
1 0 0 0 ; 2 5 0 0 ; 3 5 0 5 ; 4 0 0 5
5 0 7 0 ; 6 2.5 7 0 ; 7 5 7 0 ; 8 5 7 2.5
9 5 7 5 ; 10 2.5 7 5 ; 11 0 7 5
12 0 7 2.5 ; 13 2.5 7 2.5

The joint number followed by the X, Y and Z coordinates are specified above.

Note: Semicolons (;) are used as line separators to allow for input of multiple sets of data on one line.

MEMBER INCIDENCES
1 1 5 ; 2 2 7 ; 3 3 9 ; 4 4 11 ; 5 5 6 ; 6 6 7
7 7 8 ; 8 8 9 ; 9 9 10 ; 10 10 11 ; 11 11 12 ; 12 12 5
13 6 13 ; 14 13 10 ; 15 8 13 ; 16 13 12

The members are defined by the joints to which they are connected.

UNIT MMS
MEMBER PROPERTIES

Figure 505: Example Problem No. 22
Members 1 to 16 are defined as PRISmatic sections with width and depth values provided using the YD and ZD options. The UNIT command is specified to change the units for length from METER to MMS.

Joints 1 to 4 are declared to be pinned-supported.

The modulus of elasticity (E), density and Poisson’s ratio are specified following the command CONSTANTS. Built-in default values for concrete are used.

There are two stages in the command specification required for a time-history analysis. The first stage is defined above. Here, the parameters of the sinusoidal loading are provided.

Each data set is individually identified by the number that follows the TYPE command. In this file, only one data set is defined, which is apparent from the fact that only one TYPE is defined.

The word FORCE that follows the TYPE 1 command signifies that this data set is for a forcing function. (If you want to specify an earthquake motion, an ACCELERATION may be specified.)

The command FUNCTION SINE indicates that instead of providing the data set as discrete TIME-FORCE pairs, a sinusoidal function, which describes the variation of force with time, is provided.

The parameters of the sine function, such as FREQUENCY, AMPLITUDE, and number of CYCLES of application are then defined. STAAD internally generates discrete TIME-FORCE pairs of data from the sine function in steps of time defined by the default value (see section 5.31.4 of the Technical Reference Manual on page 2630 for more information). The arrival time value indicates the relative value of time at which the force begins to act upon the structure. The modal damping ratio for all the modes is set to 0.075.

The word FORCE that follows the TYPE 1 command signifies that this data set is for a forcing function. (If you want to specify an earthquake motion, an ACCELERATION may be specified.)

The command FUNCTION SINE indicates that instead of providing the data set as discrete TIME-FORCE pairs, a sinusoidal function, which describes the variation of force with time, is provided.

The parameters of the sine function, such as FREQUENCY, AMPLITUDE, and number of CYCLES of application are then defined. STAAD internally generates discrete TIME-FORCE pairs of data from the sine function in steps of time defined by the default value (see section 5.31.4 of the Technical Reference Manual on page 2630 for more information). The arrival time value indicates the relative value of time at which the force begins to act upon the structure. The modal damping ratio for all the modes is set to 0.075.
The above data describe a static load case. A uniformly distributed load of 10 kN/m acting in the negative global Y direction is applied on some members.

```
LOAD 2
  SELFWEIGHT X 1.0
  SELFWEIGHT Y 1.0
  SELFWEIGHT Z 1.0
  JOINT LOAD
  8 12 FX 15.0
  8 12 FY 15.0
  8 12 FZ 15.0
  TIME LOAD
  8 12 FX 1 1
```

This is the second stage of command specification for time history analysis. The two sets of data specified here are:

a. the weights for generation of the mass matrix

b. the application of the time varying loads on the structure.

The weights (from which the masses for the mass matrix are obtained) are specified in the form of selfweight and joint loads.

Following that, the sinusoidal force is applied using the `TIME LOAD` command. The forcing function described by the `TYPE 1` load is applied on joints 8 and 12 and it starts to act starting at a time defined by the 1st arrival time number.

```
PERFORM ANALYSIS
PRINT ANALYSIS RESULTS
FINI
```

The above commands are self explanatory. The `FINISH` command terminates the STAAD run.

EX. UK-23 Spring Support Generation for a Slab on Grade

This example illustrates the usage of commands necessary to automatically generate spring supports for a slab on grade. The slab is subjected to pressure loading and analysis of the structure is performed.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-23 Spring Support Generation for a Slab on Grade.STD when you install the program.

Figure 506: Example Problem No. 23

where:

H = 43m, h1 = 2.83m, h2 = 2.67m, h3 = 2m
V = 13.33m, v1 = 2.17m, v2 = 2m, v3 = 2.61m, v4 = 1.33m

STAAD SPACE SLAB ON GRADE

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. The remainder of the words form a title to identify this project.
The units for the data that follows are specified above.

JOINT COORDINATES
1 0.0 0.0 13.33
2 0.0 0.0 12.0
3 0.0 0.0 9.39
4 0.0 0.0 6.78
5 0.0 0.0 4.17
6 0.0 0.0 2.17
7 0.0 0.0 0.0
REPEAT ALL 3 2.83 0.0 0.0
REPEAT 3 2.67 0.0 0.0
REPEAT 5 2 0.0 0.0
REPEAT 3 2.67 0.0 0.0
REPEAT 3 2.83 0.0 0.0

For joints 1 through 7, the joint number followed by the X, Y, and Z coordinates are specified above. The coordinates of these joints is used as a basis for generating 21 more joints by incrementing the X coordinate of each of these seven joints by 2.83 meters, three times. REPEAT commands are used to generate the remaining joints of the structure. The results of the generation may be visually verified using the STAAD graphical viewing facilities.

ELEMENT INCIDENCES
1 1 8 9 2 TO 6
REPEAT 16 6 7

The incidences of element number 1 is defined and that data is used as a basis for generating the 2nd through the 6th element. The incidence pattern of the first six elements is then used to generate the incidences of 96 (= 16 x 6) more elements using the REPEAT command.

UNIT CM
ELEMENT PROPERTIES
1 TO 102 TH 14.0

The thickness of elements 1 to 102 is specified as 14 cms following the command ELEMENT PROPERTIES.

UNIT MMS
DEFINE MATERIAL START
ISOTROPIC CONCRETE
E 21.0
POISSON 0.17
DENSITY 2.36158e-008

END DEFINE MATERIAL
CONSTANTS
MATERIAL CONCRETE ALL
UNIT METER

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

SUPPORTS
1 TO 126 ELASTIC MAT DIRECTION Y SUB 1570.

The above command is used to instruct STAAD to generate supports with springs which are effective in the global Y direction. These springs are located at nodes 1 to 126. The subgrade modulus of the soil is specified as
1570 KN/cu.m. The program will determine the area under the influence of each joint and multiply the influence area by the subgrade reaction to arrive at the spring stiffness for the FY degree of freedom at the joint. See Section 5.27.3 in the STAAD Technical Reference Manual (on page 2517).

PRINT SUPP INFO

This command will enable us to obtain the details of the support conditions which were generated using the earlier commands.

LOAD 1 WEIGHT OF MAT & EARTH
   ELEMENT LOAD
   1 TO 102 PR GY -74.2

The above data describe a static load case. A pressure load of 74.2 kN/sq.m. acting in the negative global Y direction is applied on all the 102 elements.

LOAD 2 'COLUMN LOAD-DL+LL'
   JOINT LOADS
   1 2 FY -965.

   29 30 FY -912.
   26 FY -2414.
   27 FY -4928.
   43 44 50 51 71 72 78 79 FY -1368.
   47 54 82 FY -2350.
   92 93 FY -912.
   99 100 FY -1824.
   103 FY -2166.
   104 FY -4333.
   113 114 FY -485.
   119 121 FY -965.
   120 121 FY -1216.
   125 FY -2431.

Load case 2 consists of several joint loads acting in the negative global Y direction.

LOADING COMBINATION 101 TOTAL LOAD
   1 1. 2 1.

A load combination case, identified with load case number 101, is specified above. It instructs STAAD to factor loads 1 and 2 by a value of 1.0 and then algebraically add the results.

PERFORM ANALYSIS

The analysis is initiated using the above command.

UNIT CM

LOAD LIST 101
PRINT JOINT DISPLACEMENTS LIST 33 56
PRINT ELEMENT STRESSES LIST 34 67

Joint displacements for joints 33 and 56, and element stresses for elements 34 and 67, for load case 101, is obtained with the help of the above commands.

FINISH

The STAAD run is terminated.

EX. UK-24 Analysis of a Concrete Block Using Solid Elements

This is an example of the analysis of a structure modeled using solid finite elements. This example also illustrates the method for applying an enforced displacement on the structure.

This problem is installed with the program by default to C: \Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-24 Analysis of a Concrete Block Using Solid Elements.STD when you install the program.
STAAD SPACE

*EXAMPLE PROBLEM USING SOLID ELEMENTS

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. The comment line which begins with an asterisk is an optional title to identify this project.

UNIT KNS MET

The units for the data that follows are specified above.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  0.0  0.0  2.0  4  0.0  3.0  2.0</td>
</tr>
<tr>
<td>5  1.0  0.0  2.0  8  1.0  3.0  2.0</td>
</tr>
<tr>
<td>9  2.0  0.0  2.0 12  2.0  3.0  2.0</td>
</tr>
<tr>
<td>21  0.0  0.0  1.0 24  0.0  3.0  1.0</td>
</tr>
<tr>
<td>25  1.0  0.0  1.0 28  1.0  3.0  1.0</td>
</tr>
<tr>
<td>29  2.0  0.0  1.0 32  2.0  3.0  1.0</td>
</tr>
<tr>
<td>41  0.0  0.0  0.0 44  0.0  3.0  0.0</td>
</tr>
<tr>
<td>45  1.0  0.0  0.0 48  1.0  3.0  0.0</td>
</tr>
<tr>
<td>49  2.0  0.0  0.0 52  2.0  3.0  0.0</td>
</tr>
</tbody>
</table>

The joint number followed by the X, Y, and Z coordinates are specified above. The coordinates of some of those nodes are generated utilizing the fact that they are equally spaced between the extremities.

<table>
<thead>
<tr>
<th>ELEMENT INCIDENCES SOLID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  1  5  6  2  21  25  26  22  T0  3</td>
</tr>
</tbody>
</table>
The incidences of solid elements are defined above. The word SOLID is used to signify that these are 8-node solid elements as opposed to 3-noded or 4-noded plate elements. Each line contains the data for generating 3 elements. For example, element number 1 is first defined by all of its 8 nodes. Then, increments of 1 to the joint number and 1 to the element number (the defaults) are used for generating incidences for elements 2 and 3. Similarly, incidences of elements 4, 7 and 10 are defined while those of 5, 6, 8, 9, 11 and 12 are generated.

UNIT METERL

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

PRINT ELEMENT INFO SOLID LIST 1 TO 5

This command will enable us to obtain, in a tabular form, the details of the incidences and material property values of elements 1 to 5.

SUPPORTS
  1 5 21 25 29 41 45 49 PINNED
  9 ENFORCED

The above lines contain the data for supports for the model. The ENFORCED support condition is used to declare a point at which an enforced displacement load is applied later (see load case 3).

LOAD 1
  SELF Y -1.0
  JOINT LOAD
  28 FY -1000.0

The above data describe a static load case. It consists of selfweight loading and a joint load, both in the negative global Y direction.

LOAD 2
  JOINT LOADS
  2 TO 4 22 TO 24 42 TO 44 FX 100.0

Load case 2 consists of several joint loads acting in the positive global X direction.

LOAD 3
  SUPPORT DISPLACEMENT
  9 FX 0.0011
Load case 3 consists of an enforced displacement along the global X direction at node 9. The displacement in the other enforced support degrees of freedom will default to zero.

```
UNIT POUND FEET
LOAD 4
ELEMENT LOAD SOLIDS
  3 6 9 12 FACE 4 PRE GY -500.0
```

In Load case 4, a pressure load of 500 pounds/sq.ft is applied on Face # 4 of solid elements 3, 6, 9 and 12. Face 4 is defined as shown in the following table:

<table>
<thead>
<tr>
<th>Face Number</th>
<th>Surface Joints</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>f1</td>
</tr>
<tr>
<td>1 front</td>
<td>Jt 1</td>
</tr>
<tr>
<td>2 bottom</td>
<td>Jt 1</td>
</tr>
<tr>
<td>3 left</td>
<td>Jt 1</td>
</tr>
<tr>
<td>4 top</td>
<td>Jt 4</td>
</tr>
<tr>
<td>5 right</td>
<td>Jt 2</td>
</tr>
<tr>
<td>6 back</td>
<td>Jt 5</td>
</tr>
</tbody>
</table>

The above table, and other details of this type of loading can be found in section 5.32.3.2 of the STAAD.Pro Technical Reference manual (on page 2660).

```
UNIT KNS MMS
LOAD 5
REPEAT LOAD
  1 1.0 2 1.0 3 1.0 4 1.0
```

Load case 5 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases already specified earlier. We want the program to analyze the structure for loads from cases 1 through 4 acting simultaneously. In other words, the above instruction is the same as the following:

```
LOAD 5
SELF Y -1.0
JOINT LOAD
  28 FY -1000.0
  2 TO 4 22 TO 24 42 TO 44 FX 100.0
SUPPORT DISPLACEMENT
  9 FX .0011
ELEMENT LOAD SOLIDS
  3 6 9 12 FACE 4 PRE GY -500.0
LOAD COMB 10
  1 1.0 2 1.0
```

Load case 10 is a combination load case, which combines the effects of cases 1 & 2. While the syntax of this might look very similar to that of the REPEAT LOAD case shown in case 5, there is a fundamental difference. In a REPEAT LOAD case, the program computes the displacements by multiplying the inverted stiffness matrix by the...
load vector built for the REPEAT LOAD case. But in solving load combination cases, the program merely calculates the end results (displacements, forces, reactions) by gathering up the corresponding values from the individual components of the combination case, factoring them, and then algebraically summing them up. This difference in approach is quite important in that non-linear problems such as PDELTA ANALYSIS, MEMBER TENSION, and MEMBER COMPRESSION situations, changes in support conditions etc. should be handled using REPEAT LOAD cases, not load combination cases.

PERFORM ANALYSIS PRINT STATICS CHECK

A static equilibrium report, consisting of total applied loading and total support reactions from each primary load case is requested along with the instructions to carry out a linear static analysis.

PRINT JOINT DISPLACEMENTS LIST 8 9

Global displacements at nodes 8 and 9 are obtained using the above command.

UNIT KNS METER
PRINT SUPPORT REACTIONS

Reactions at the supports are obtained using the above command.

UNIT NEWTON MMS
PRINT ELEMENT JOINT STRESS SOLID LIST 4 6

This command requests the program to provide the element stress results at the nodes of elements 4 and 6. The results will be printed for all the load cases. The word SOLID is used to signify that these are solid elements as opposed to plate or shell elements.

FINISH

The STAAD run is terminated.

**EX. UK-25 Analysis of a Structure with Compression-Only Members**

This example demonstrates the usage of compression-only members. Since the structural condition is load dependent, the **PERFORM ANALYSIS** command is specified once for each primary load case.

This problem is installed with the program by default to

C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-25 Analysis of a Structure with Compression-Only Members.STD when you install the program.
This example has been created to illustrate the command specification for a structure with certain members capable of carrying compressive force only. It is important to note that the analysis can be done for only 1 load case at a time. This is because, the set of “active” members (and hence the stiffness matrix) is load case dependent.

where:

\[
L = 5.25 \text{ m}, \quad H = 3.5 \text{ m} \\
\text{Load case 1: } P_1 = 45 \text{ kN} \quad \text{&} \quad P_2 = 70 \text{ kN} \\
\text{Load case 2: } P_3 = -45 \text{ kN} \quad \text{&} \quad P_4 = -70 \text{ kN}
\]

STAAD PLANE

* EXAMPLE FOR COMPRESSION-ONLY MEMBERS

The input data is initiated with the word STAAD. This structure is a PLANE frame. The second line is an optional comment line.

UNIT METER KNS

Units for the commands to follow are specified above.

JOINT COORDINATES
1 0 0 ; 2 0 3.5 ; 3 0 7.0 ; 4 5.25 7.0 ; 5 5.25 3.5 ; 6 5.25 0
Joint coordinates of joints 1 to 6 are defined above.

```
MEMBER INCIDENCES
  1 1 2 5 ; 6 1 5 ; 7 2 6 ; 8 2 4 ; 9 3 5 ; 10 2 5
```

The members 1 to 10 are defined along with the joints to which they are connected.

```
MEMBER COMPRESSION
  6 TO 9
```

Members 6 to 9 are defined as COMPRESSION-only members. Hence for each load case, if during the analysis, any of the members 6 to 9 is found to be carrying a tensile force, it is disabled from the structure and the analysis is carried out again with the modified structure.

```
MEMBER PROPERTY BRITISH
  1 TO 10 TA ST UC152X152X30
```

Members 1 to 10 are assigned the UC152X152X30 section from the British steel table.

```
UNIT MMS
DEFINE MATERIAL START
  ISOTROPIC STEEL
  E 210
  POISSON 0.3
  DENSITY 7.6977e-008
  ALPHA 6e-006
  DAMP 0.03
  TYPE STEEL
  STRENGTH FY 0.25 FU 0.4 RY 1.5 RT 1.2
END DEFINE MATERIAL
CONSTANTS
  MATERIAL STEEL ALL
  UNIT METER
```

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members.

```
SUPPORT
  1 6 PINNED
```

Joints 1 and 6 are declared as pinned-supported.

```
LOAD 1
  JOINT LOAD
  2 FX 70
  3 FX 45
```

Load 1 is defined above and consists of joint loads in the global X direction at joints 2 and 3.

```
PERFORM ANALYSIS
```

The above structure is analyzed for load case 1.

```
CHANGE
  MEMBER COMPRESSION
  6 TO 9
```

One or more among the members 6 to 9 may have been in-activated in the previous analysis. The CHANGE command restores the original structure to prepare it for the analysis for the next primary load case. The members with the compression-only attribute are specified again.

```
LOAD 2
  JOINT LOAD
```
In load case 2, joint loads are applied in the negative global X direction at joints 4 and 5.

```
PERFORM ANALYSIS
CHANGE
```

The instruction to analyze the structure is specified again. Next, any compression-only members that were inactivated during the second analysis (due to the fact that they were subjected to tensile axial forces) are re-activated with the CHANGE command. Without the re-activation, these members cannot be accessed for further processing.

```
LOAD 3
REPEAT LOAD
1 1.0 2 1.0
```

Load case 3 illustrates the technique employed to instruct STAAD to create a load case which consists of data to be assembled from other load cases already specified earlier. We would like the program to analyze the structure for loads from cases 1 and 2 acting simultaneously. In other words, the above instruction is the same as the following:

```
LOAD 3
JOINT LOAD
2 FX 70
3 FX 45
4 FX -45
5 FX -70
PERFORM ANALYSIS
```

The analysis is carried out for load case 3.

```
CHANGE
```

The members inactivated during the analysis of load case 3 are re-activated for further processing.

```
LOAD LIST ALL
```

At the end of any analysis, only those load cases for which the analysis was done most recently, are recognized as the “active” load cases. The LOAD LIST ALL command enables all the load cases in the structure to be made active for further processing.

```
PRINT ANALYSIS RESULTS
```

The program is instructed to write the joint displacements, support reactions and member forces to the output file.

```
FINISH
```

The STAAD run is terminated.

*EXAMPLE FOR COMPRESSION-ONLY MEMBERS*
EX. UK-26 Modeling a Rigid Diaphragm Using Master-Slave

The structure in this example is a building consisting of member columns as well as floors made up of beam members and plate elements. Using the master-slave command, the floors are specified to be rigid diaphragms for in-plane actions but flexible for bending actions.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-26 Modeling a Rigid Diaphragm Using Master-Slave.STD when you install the program.
Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The second line is an optional title to identify this project.

Specify units for the following data.

| JOINT COORD | 1 0 0 0 4 0 48 0 |
| REPEAT 3 24 0 0 |
| REPEAT ALL 3 0 0 24 |
| DELETE JOINT 21 25 37 41 |

The joint numbers and coordinates are specified above. The unwanted joints, created during the generation process used above, are then deleted.

| MEMBER INCI | 1 1 2 3 ; 4 5 6 6 ; 7 9 10 9 ; 10 13 14 12 |

**EX. UK-27 Modeling Soil Springs for a Slab on Grade**

This example illustrates the usage of commands necessary to apply the compression only attribute to spring supports for a slab on grade. The spring supports themselves are generated utilizing the built-in support generation facility. The slab is subjected to pressure and overturning loading. A tension/compression only analysis of the structure is performed.

This problem is installed with the program by default to 
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-27 Modeling Soil Springs for a Slab on Grade.STD when you install the program.

The numbers shown in the diagram below are the element numbers.
where:

\[
H = 129', h_1 = 8'-6'', h_2 = 8', h_3 = 6'
\]
\[
V = 40', v_1 = 6'-6'', v_2 = 6', v_3 = 7'-10'', v_4 = 4'
\]

STAAD SPACE SLAB ON GRADE
* SPRING COMPRESSION EXAMPLE

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y, and Z axes. An optional title to identify this project is provided in the second line.

SET NL 3

This structure has to be analyzed for 3 primary load cases. Consequently, the modeling of our problem requires us to define 3 sets of data, with each set containing a load case and an associated analysis command. Also, the supports which get switched off in the analysis for any load case have to be restored for the analysis for the subsequent load case. To accommodate these requirements, it is necessary to have 2 commands: SET NL and CHANGE. The SET NL command is used above to indicate the total number of primary load cases that the file contains. The CHANGE command will come in later (after the PERFORM ANALYSIS command).
For joints 1 through 7, the joint number followed by the X, Y and Z coordinates are specified above. The coordinates of these joints is used as a basis for generating 21 more joints by incrementing the X coordinate of each of these 7 joints by 8.5 feet, 3 times. REPEAT commands are used to generate the remaining joints of the structure. The results of the generation may be visually verified using the STAAD graphical viewing facilities.

```
ELEMENT INCIDENCES
1 1 8 9 2 TO 6
REPEAT 16 6 7
```

The incidences of element number 1 is defined and this data is used as a basis for generating the 2nd through the 6th element. The incidence pattern of the first 6 elements is then used to generate the incidences of 96 more elements using the REPEAT command.

```
UNIT INCH
ELEMENT PROPERTIES

```

The above two lines declare the spring supports at nodes 1 to 126 as having the compression-only attribute. The supports themselves are being generated later (see the ELASTIC MAT command which appears later).

```
UNIT FEET
SUPPORTS
1 TO 126 ELASTIC MAT DIRECTION Y SUBGRADE 12.0
```

The above command is used to instruct STAAD to generate supports with compression-only springs which are effective in the global Y direction. These springs are located at nodes 1 to 126. The subgrade reaction of the soil is specified as 12 kip/cu.ft. The program will determine the area under the influence of each joint and multiply the influence area by the subgrade reaction to arrive at the spring stiffness for the "FY" degree of freedom at the joint. Units for length are changed to FEET to facilitate the input of subgrade reaction of soil. See TR.27.3 Automatic Spring Support Generator for Foundations (on page 2517).

```
LOAD 1 'WEIGHT OF MAT & EARTH'

STAAD.Pro  4872  User Manual
EX. UK-28 Calculation of Modes and Frequencies of a Bridge

This example demonstrates the input required for obtaining the modes and frequencies of the skewed bridge shown in the figure below. The structure consists of piers, pier-cap girders and a deck slab.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-28 Calculation of Modes and Frequencies of a Bridge.std when you install the program.

Figure 511: Example Problem No. 28

STAAD SPACE FREQUENCIES OF VIBRATION OF A SKEWED BRIDGE

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The remainder of the words forms a title to identify this project.

IGNORE LIST

Further below in this file, we will call element lists in which some element numbers may not actually be present in the structure. We do so because it minimizes the effort involved in fetching the desired elements and reduces the size of the respective commands. To prevent the program from treating that condition (referring to elements which do not exist) as an error, the above command is required.

UNIT METER KN
Application Examples

EX. British Design Examples

The units for the data that follows are specified above.

<table>
<thead>
<tr>
<th>JOINT COORDINATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0 0; 2 4 0 0; 3 6.5 0 0; 4 9 0 0; 5 11.5 0 0; 6 15.5 0 0;</td>
</tr>
<tr>
<td>11 -1 10 25.165 0 10 0</td>
</tr>
<tr>
<td>REPEAT ALL 3 4 0 14</td>
</tr>
</tbody>
</table>

For joints 1 through 6, the joint number followed by the X, Y and Z coordinates are specified first.

Next, using the coordinates of joints 11 and 25 as the basis, joints 12 through 24 are generated using linear interpolation.

Following this, using the data of these 21 joints (1 through 6 and 11 through 25), 63 new joints are generated. To achieve this, the X coordinate of these 21 joints is incremented by 4 meters and the Z coordinate is incremented by 14 meters, in 3 successive operations.

The REPEAT ALL command is used for the generation. Details of this command is available in TR.11 Joint Coordinates Specification (on page 2425). The results of the generation may be visually verified using STAAD.Pro's graphical viewing facilities.

<table>
<thead>
<tr>
<th>MEMBER INCI</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 1 13 ; 2 2 15 ; 3 3 17 ; 4 4 19 ; 5 5 21 ; 6 6 23</td>
</tr>
<tr>
<td>26 26 34 ; 27 27 36 ; 28 28 38 ; 29 29 40 ; 30 30 42 ; 31 31 44</td>
</tr>
<tr>
<td>47 47 55 ; 48 48 57 ; 49 49 59 ; 50 50 61 ; 51 51 63 ; 52 52 65</td>
</tr>
<tr>
<td>68 68 76 ; 69 69 78 ; 70 70 80 ; 71 71 82 ; 72 72 84 ; 73 73 86</td>
</tr>
</tbody>
</table>

The member connectivity data (joint numbers between which members are connected) is specified for the 24 columns for the structure. The above method, where the member number is followed by the 2 node numbers, is the explicit definition method. No generation is involved here.

| 101 11 12 114 |
| 202 32 33 215 |
| 303 53 54 316 |
| 404 74 75 417 |

The member connectivity data is specified for the pier cap beams for the structure. The above method is a combination of explicit definition and generation. For example, member 101 is defined as connected between 11 & 12. Then, by incrementing those nodes by 1 unit at a time (which is the default increment), the incidences of members 102 to 114 are generated. Similarly, we create members 202 to 215, 303 to 316, and, 404 to 417.

<table>
<thead>
<tr>
<th>DEFINE MESH</th>
</tr>
</thead>
<tbody>
<tr>
<td>A JOINT 11</td>
</tr>
<tr>
<td>B JOINT 25</td>
</tr>
<tr>
<td>C JOINT 46</td>
</tr>
<tr>
<td>D JOINT 32</td>
</tr>
<tr>
<td>E JOINT 67</td>
</tr>
<tr>
<td>F JOINT 53</td>
</tr>
<tr>
<td>G JOINT 88</td>
</tr>
<tr>
<td>H JOINT 74</td>
</tr>
</tbody>
</table>

The next step is to generate the deck slab which will be modeled using plate elements. For this, we use a technique called mesh generation. Mesh generation is a process of generating several "child" elements from a "parent" or "super" element. The above set of commands defines the corner nodes of the super-element. Details of the above can be found in Section 5.14 of the Technical Reference manual.

Note that instead of elaborately defining the coordinates of the corner nodes of the super-elements, we have taken advantage of the fact that the coordinates of these joints (A through H) have already been defined or
generated earlier. Thus, A is the same as joint 11 while D is the same as joint 32. Alternatively, we could have defined the super-element nodes as A -1 10 0 ; B 16.5 10 0 ; C 20.5 10 14 ; D 3 10 14 ; etc.

| GENERATE ELEMENT | MESH ABCD 14 12 | MESH DCEF 14 12 | MESH FEGH 14 12 |

The above lines are the instructions for generating the “child” elements from the super-elements. For example, from the super-element bound by the corners A, B, C and D (which in turn are nodes 11, 25, 46 and 32), we generate a total of 14X12=168 elements, with 14 divisions along the edges AB and CD, and 12 along the edges BC and DA. These are the elements which make up the first span.

Similarly, 168 elements are created for the 2nd span, and another 168 for the 3rd span.

It may be noted here that we have taken great care to ensure that the resulting elements and the piercap beams form a perfect fit. In other words, there is no overlap between the two in a manner that nodes of the beams are at a different point in space than nodes of elements. At every node along their common boundary, plates and beams are properly connected. This is absolutely essential to ensure proper transfer of load and stiffness from beams to plates and vice versa. The tools of the graphical user interface may be used to confirm that beam-plate connectivity is proper for this model.

| END GROUP DEFINITION |

The above block of data is referred to as formation of groups. Group names are a mechanism by which a single moniker can be used to refer to a cluster of entities, such as members. For our structure, the piercap beams are being grouped to a name called GIRDERS, the pier columns are assigned the name PIERS, and so on. For the deck, a few selected elements are chosen into a few selective groups. The reason is that these elements happen to be right beneath wheels of vehicles whose weight will be used in the frequency calculation.

| MEMBER PROPERTY |
| _GIRDERS PRIS YD 0.6 ZD 0.6 |
| _PIERS PRIS YD 1.0 |

Member properties are assigned as prismatic rectangular sections for the girders, and prismatic circular sections for the columns.

| ELEMENT PROPERTY |
| YRA 9 11 TH 0.375 |

The plate elements of the deck slab, which happen to be at a Y elevation of 10 metres (between a YRANGE of 9 metres and 11 metres) are assigned a thickness of 375 mms.

| UNIT KNS MMS |
| DEFINE MATERIAL START |
| ISOTROPIC CONCRETE |
| E 21.0 |
| POISSON 0.17 |
| DENSITY 2.36158e-008 |
The Modulus of elasticity (E) is set to 21000 N/sq.mm for all members. The keyword CONSTANTS has to precede this data. Built-in default value for Poisson's ratio for concrete is also assigned to ALL members and elements.

Following a change of units, density of concrete is specified.

The base nodes of the piers are fully restrained (FIXED supports).

Theoretically, a structure has as many modes of vibration as the number of degrees of freedom in the model. However, the limitations of the mathematical process used in extracting modes may limit the number of modes that can actually be extracted. In a large structure, the extraction process can also be very time consuming. Further, not all modes are of equal importance. (One measure of the importance of modes is the participation factor of that mode.) In many cases, the first few modes may be sufficient to obtain a significant portion of the total dynamic response.

Due to these reasons, in the absence of any explicit instruction, STAAD calculates only the first 6 modes. This is like saying that the command CUT OFF MODE SHAPE 6 has been specified. (Versions of STAAD prior to STAAD.Pro 2000 calculated only 3 modes by default).

If the inspection of the first 6 modes reveals that the overall vibration pattern of the structure has not been obtained, one may ask STAAD to compute a larger (or smaller) number of modes with the help of this command. The number that follows this command is the number of modes being requested. In our example, we are asking for 65 modes by specifying CUT OFF MODE SHAPE 65.
The mathematical method that STAAD uses is called the eigen extraction method. Some information on this is available in G.17.3 Dynamic Analysis (on page 2362). The method involves 2 matrices - the stiffness matrix, and the mass matrix.

The stiffness matrix, usually called the \([K]\) matrix, is assembled using data such as member and element lengths, member and element properties, modulus of elasticity, Poisson’s ratio, member and element releases, member offsets, support information, etc.

For assembling the mass matrix, called the \([M]\) matrix, STAAD uses the load data specified in the load case in which the MODAL CAL REQ command is specified. So, some of the important aspects to bear in mind are:

1. The input you specify is weights, not masses. Internally, STAAD will convert weights to masses by dividing the input by "g", the acceleration due to gravity.
2. If the structure is declared as a PLANE frame, there are 2 possible directions of vibration - global X, and global Y. If the structure is declared as a SPACE frame, there are 3 possible directions - global X, global Y and global Z. However, this does not guarantee that STAAD will automatically consider the masses for vibration in all the available directions.

You have control over and are responsible for specifying the directions in which the masses ought to vibrate. In other words, if a weight is not specified along a certain direction, the corresponding degrees of freedom (such as for example, global X at node 34 hypothetically) will not receive a contribution in the mass matrix. The mass matrix is assembled using only the masses from the weights and directions you specify.

In our example, notice that we are specifying the selfweight along global X, Y and Z directions. Similarly, a 200 kg/sq.m pressure load is also specified along all 3 directions on the deck.

But for the truck loads, we choose to apply it on just a few elements in the global Y and Z directions only. The reasoning is something like - for the X direction, the mass is not capable of vibrating because the tires allow the truck to roll along X. Remember, this is just a demonstration example, not necessarily what you may want to do.

The point we want to illustrate is that if a user wants to restrict a certain weight to certain directions only, all he/she has to do is not provide the directions in which those weights cannot vibrate in.

3. As much as possible, provide absolute values for the weights. STAAD is programmed to algebraically add the weights at nodes. So, if some weights are specified as positive numbers and others as negative, the total weight at a given node is the algebraic summation of all the weights in the global directions at that node and the mass is then derived from this algebraic resultant.

This is the command which tells the program that frequencies and modes should be calculated. It is specified inside a load case. In other words, this command accompanies the loads that are to be used in generating the mass matrix.

Frequencies and modes have to be calculated also when dynamic analysis such as response spectrum or time history analysis is carried out. But in such analyses, the MODAL CALCULATION REQUESTED command is not explicitly required. When STAAD encounters the command for response spectrum (see example 11) and time history (see examples 16 and 22), it automatically will carry out a frequency extraction without the help of the MODAL.. command.
This initiates the processes which are required to obtain the frequencies. Frequencies, periods and participation factors are automatically reported in the output file when the operation is completed.

**FINISH**

This terminates the STAAD run.

</table>
In the explanation earlier for the CUT OFF MODE command, we said that one measure of the importance of a mode is the participation factor of that mode. We can see from the above report that for vibration along Z direction, the first mode has a 99.04 percent participation. It is also apparent that the 7th mode is primarily a Y direction mode with a 26.42% participation along Y and 0 in X and Z.

The \( \Sigma X, \Sigma Y \) and \( \Sigma Z \) columns show the cumulative value of the participation of all the modes up to and including a given mode (Corresponding to the SUMM-X, SUMM-Y, and SUMM-Z reported in the output, respectively). One can infer from those terms that if one is interested in 95% participation along X, the first 2 modes are sufficient.

But for the Y direction, even with 10 modes, we barely obtained 60%. The reason for this can be understood by an examination of the nature of the structure. The deck slab is capable of vibrating in several low energy and primarily vertical direction modes. The out-of-plane flexible nature of the slab enables it to vibrate in a manner resembling a series of wave like curves. Masses on either side of the equilibrium point have opposing eigenvector values leading to a lot of cancellation of the contribution from the respective masses. Localized modes, where small pockets in the structure undergo flutter due to their relative weak stiffness compared to the rest of the model, also result in small participation factors.

iii. After the analysis is completed, select Post-processing from the mode menu. This screen contains facilities for graphically examining the shape of the mode in static and animated views. The Dynamics page on the left side of the screen is available for viewing the shape of the mode statically. The Animation option of the Results menu can be used for animating the mode. The mode number can be selected from the Loads and Results tab of the Diagnostics dialog box which opens when the Animation option is chosen. The size to which the mode is drawn is controlled using the Scales tab of the Diagnostics dialog box.

EX. UK-29 Time History Analysis of a Frame for Seismic Loads

Analysis and design of a structure for seismic loads is demonstrated in this example. In this model, static load cases are solved along with the seismic load case. For the seismic case, the maximum values of displacements, forces and reactions are obtained. The results of the dynamic case are combined with those of the static cases and steel design is performed on the combined cases.

This problem is installed with the program by default to C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK-29 Time History Analysis of a Frame for Seismic Loads.std when you install the program.
Actual input is shown in bold lettering followed by explanation.

**STAAD SPACE DYNAMIC ANALYSIS FOR SEISMIC LOADS**

Every STAAD input file has to begin with the word STAAD. The word SPACE signifies that the structure is a space frame and the geometry is defined through X, Y and Z axes. The remainder of the words form a title to identify this project.

**UNIT METER KNS**

The units for the data that follows are specified above.

**JOINT COORDINATES**

1 0 0 0 ; 2 0 3.5 0 ; 3 0 5.3 0 ; 4 0 7 0
REPEAT ALL 1 9.5 0 0
REPEAT ALL 1 0 0 3
17 1.8 7 0 ; 18 4.6 7 0 ; 19 7.6 7 0
REPEAT ALL 1 0 0 3

For joints 1 through 4, the joint number is followed by the X, Y and Z coordinates as specified above. The coordinates of these joints are used as a basis for generating 12 more joints by incrementing the X & Z coordinates by specific amounts. REPEAT ALL commands are used for the generation. Details of these commands are available in Section 5.11 of the Technical Reference manual. Following this, another round of explicit definition (joints 17, 18 & 19) and generation (20, 21 & 22) is carried out. The results of the generation may be visually verified using graphical view features in STAAD.Pro.

**MEMBER INCIDENCES**

1 1 2 3
REPEAT 1 3 4
7 9 10 9
A mixture of explicit definition and generation of member connectivity data (joint numbers between which members are connected) is used to generate 29 members for the structure.

START GROUP DEFINITION
MEMBER
  _VERTICAL 1 TO 12
  _XBEAM 13 TO 20
  _ZBEAM 21 TO 24 29
  _BRACE 25 TO 28
END GROUP DEFINITION

The above block of data is referred to as formation of groups. Group names are a mechanism by which a single moniker can be used to refer to a cluster of entities, such as members. For our structure, the columns are being grouped to a name called VERTICAL, the beams running along the X direction are assigned the name XBEAM, and so on.

MEMBER PROPERTIES CANADIAN
  _VERTICAL TA ST W310X97
  _XBEAM TA ST W250X39
  _ZBEAM TA ST C200X17
  _BRACE TA ST L152X152X13

Member properties are assigned from the Canadian steel table. The members which receive these properties are those embedded within the respective group names. The benefit of using the group name is apparent here. Just from the looks of the command, we can understand that the diagonal braces are being assigned a single angle. The alternative, which would be

25 TO 28 TA ST L152X152X13

would have required us to go to the graphical tools to get a sense of what members 25 to 28 are.

UNIT KNS MMS

CONSTANTS
  MATERIAL STEEL ALL
  BETA 180 MEMB 21 22

The DEFINE MATERIAL command is used to specify material properties and the CONSTANT is used to assign the material to all members. The BETA angle for the channels along the left edge is set to 180 so their legs point toward the interior of the structure.
The bottom ends of the columns of the platform are pinned supported.

CUT OFF MODE SHAPE 30

The above command is a critical command if you want to override the default number of modes computed and used in a dynamic analysis. The default, which is 6, may not always be sufficient to capture a significant portion of the structural response in a response spectrum or time history analysis, and hence the need to override the default. This command is explained in Section 5.30 of the Technical Reference manual.

UNIT METER
DEFINE TIME HISTORY
TYPE 1 ACCELERATION
READ EQDATA.TXT
ARRIVAL TIME
0.0
DAMPING 0.05

There are two stages in the command specification required for a time-history analysis. The first stage is defined above. Here, the parameters of the earthquake (ground acceleration) are provided.

Each data set is individually identified by the number that follows the TYPE command. In this file, only one data set is defined, which is apparent from the fact that only one TYPE is defined.

The word FORCE that follows the TYPE 1 command signifies that this data set is for a ground acceleration. (If you want to specify a forcing function, the keyword FORCE must be used instead.)

Notice the expression READ EQDATA.TXT. It means that we have chosen to specify the time vs. ground acceleration data in the file called EQDATA.TXT. That file must reside in the same folder as the one in which the data file for this structure resides. As explained in the small examples shown in TR.31.4 Definition of Time History Load (on page 2630), the EQDATA.TXT file is a simple text file containing several pairs of time-acceleration data. A sample portion of that file is as shown below.

<table>
<thead>
<tr>
<th>Time (sec)</th>
<th>Acceleration (m/s²)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0000</td>
<td>0.006300</td>
</tr>
<tr>
<td>0.0200</td>
<td>0.003640</td>
</tr>
<tr>
<td>0.0400</td>
<td>0.000990</td>
</tr>
<tr>
<td>0.0600</td>
<td>0.004280</td>
</tr>
<tr>
<td>0.0800</td>
<td>0.007580</td>
</tr>
<tr>
<td>0.1000</td>
<td>0.010870</td>
</tr>
</tbody>
</table>

While it may not be apparent from the above numbers, it may also be noted that the geological data for the site the building sits on indicate that the above acceleration values are a fraction of "g", the acceleration due to gravity. Thus, for example, at 0.02 seconds, the acceleration is 0.00364 multiplied by 9.806 m/sec² (or 0.00364 multiplied by 32.2 ft/sec²). Consequently, the burden of informing the program that the values need to be multiplied by "g" is upon us, and we shall do so at a later step.

The arrival time value indicates the relative value of time at which the earthquake begins to act upon the structure. We have chosen 0.0, as there is no other dynamic load on the structure from the relative time standpoint. The modal damping ratio for all the modes is set to 0.05.

LOAD 1 WEIGHT OF STRUCTURE ACTING STATICALLY
SELFWEIGHT Y -1.0

The above data describe a static load case. The selfweight of the structure is acting in the negative global Y direction.

LOAD 2 PLATFORM LEVEL LOAD ACTING STATICALLY FLOOR LOAD
YRA 6.9 7.1 FLOAD -500
Load case 2 is also a static load case. At the Y=7.0m elevation, our structure has a floor slab. But, it is a non-structural entity which, though capable of carrying the loads acting on itself, is not meant to be an integral part of the framing system. It merely transmits the load to the beam-column grid.

There are uniform area loads on the floor (think of the load as wooden pallets supporting boxes of paper). Since the slab is not part of the structural model, how do we tell the program to transmit the imposed load from the slab to the beams without manually converting them to distributed beam loads ourselves? That is where the floor load utility comes in handy. It is a facility where we specify the load as a pressure, and the program converts the pressure to individual beam loads. Thus, the input required is very simple - load intensity in the form of pressure, and the region of the structure in terms of X, Y and Z coordinates in space, of the area over which the pressure acts.

In the process of converting the pressure to beam loads, STAAD will consider the empty space between criss-crossing beams (in plan view) to be panels, similar to the squares of a chess board. The load on each panel is then transferred to beams surrounding the panel, using a triangular or trapezoidal load distribution method.

| LOAD 3 DYNAMIC LOAD |
| * MASSES |
| SELFWEIGHT X 1.0 |
| SELFWEIGHT Y 1.0 |
| SELFWEIGHT Z 1.0 |
| FLOOR LOAD |
| YRANGE 6.9 7.1 FLOAD 500 GX |
| YRANGE 6.9 7.1 FLOAD 500 GY |
| YRANGE 6.9 7.1 FLOAD 500 GZ |

Load case 3 is the dynamic load case, the one which contains the second part of the instruction set for a dynamic analysis to be performed. The data here are

a. loads which will yield the mass values which will populate the mass matrix
b. the directions of the loads, which will yield the degree of freedom numbers of the mass matrix for being populated.

Thus, the selfweight, as well as the imposed loads on the non-structural slab are to be considered as participating in the vibration along all the global directions.

| GROUND MOTION X 1 1 9.806 |

The above command too is part of load case 3. Here we say that the seismic force, whose characteristics are defined by the TYPE 1 time history input data, acting at arrival time 1, is to be applied along the X direction. We mentioned earlier that the acceleration input data was specified as a fraction of “g”. The number 9.806 indicates the value which the acceleration data, as read from EQDATA.TXT are to be factored by before they are used.

| LOAD COMBINATION 11 (STATIC + POSITIVE OF DYNAMIC) |
| 1 1.0 2 1.0 3 1.0 |
| LOAD COMBINATION 12 (STATIC + NEGATIVE OF DYNAMIC) |
| 1 1.0 2 1.0 3 -1.0 |

In a time history analysis, the member forces FX thru MZ each have a value for every time step. If there are a 1000 time steps, there will be 1000 values of FX, 1000 for FY etc. for that load case. Not all of them can be used in a further calculation like a steel or concrete design. However, the maximum from among those time steps is available. If we want to do a design, one way to make sure that the structure is not under-designed is to create 2 load combination cases involving the dynamic case, a positive combination, and a negative combination.

That is what is being done above. Load combination case no. 11 consists of the sum of the static load cases (1 & 2) with the positive direction of the dynamic load case (3). Load combination case no. 12 consists of the sum of...
the static load cases (1 & 2) with the negative direction of the dynamic load case (3). The user has discretion on what load factors to use with these combinations. We have chosen the factors to be 1.0.

PERFORM ANALYSIS

The above is the instruction to perform the analysis related calculations. That means, computing nodal displacements, support reactions, etc.

PRINT ANALYSIS RESULTS

The above command is an instruction to the program to produce a report of the joint displacements, support reactions and member end forces in the output file. As mentioned earlier, for the dynamic case, these will be just the maximum values, not the ones generated for every time step. If you want to see the results for each time step, you may do so by using STAAD’s Post-processing facilities.

EX. Modeling Examples

These examples demonstrate using some of modeling features in STAAD.Pro.

EX. Meshed Wall-Slab Connection

This example demonstrates how to ensure finite element mesh compatibility between two adjoining meshed entities.

The Model Data

Use the Copy to clipboard button below to copy and paste this model data into an empty STAAD input file if you want to work through this example yourself.

Related Links
• M. To define a slab/wall connection (on page 660)

EX. To create a new view

To create a new view that isolates the slab members for meshing, use the following procedure.

1. On the View ribbon tab, select the Front View tool in the Tools group.
The view rotates to this angle.

2. Click-and-drag the mouse pointer from the top-left towards the bottom-right of the slab members.

   **Note:** You may need to select the **Beam Cursor** tool on the **Select** ribbon tab first.

3. On the **View** ribbon tab, select the **New View** tool in the **Views** group.

   The **New View** dialog opens.

   ![New View dialog](image)

4. Select the **Display the view in the active window** option and then click **OK**.

   The new view is displayed in the active view window. Only the selected slab members are currently displayed. The wall members are still contained in the model. They are just hidden from this view.

5. On the **View** ribbon tab, select the **Isometric View** tool in the **Tools** group.

EX. To create a parametric model

To create a slab finite element mesh, use the following procedure.

1. Select the **Parametric Models** tool in the Plate group on the **Geometry** ribbon tab.
The **Parametric Models** dialog opens. The structure is displayed as a series of dashed lines to signify this mode can be used to experiment with various settings.

2. Click **Add** in the **Parametric Models** dialog.

   The **New Mesh Model** dialog opens.

3. Specify the parametric model parameters:
   a. (Optional) Type a **Name** for the slab mesh.
   b. Select **Slab** from the **Type** drop-down list.
   c. Set the **Use nodes and beams that occur on or inside the outer boundary as additional density lines and points?** option.

4. Click **OK**.

   The mouse pointer changes to the add surface cursor.

5. Click the corner nodes of the slab in a clockwise order, clicking on the first node selected to complete the boundary definition.

   ![Diagram of a slab model with nodes and beams]

   The **Mesh Parameters** dialog opens.

6. Specify the meshing parameters:
   Leave the **Element Type** as Triangular, the **Boundary method** as (C) Optimized, and the **Default Number of Divisions of Boundary Edges** as zero.
a. Select Basic from the Meshing Method drop-down list.
b. Type a Target element size of 100 (in).
c. Click OK.
A message dialog prompts if you want to add any openings.

7. Click No.
The preliminary mesh is displayed in the view window. The mesh parameters are displayed in the Parametric Models dialog.

8. In the Parametric Models dialog, select the Meshed Surface 1 [Slab] entry and then click Merge Mesh.
EX. To designate the wall-slab connection

To mesh the wall such that it is compatible with the slab mesh, use the following procedure.

1. In the Analytical Modeling workflow bar, select Geometry.
   The Parametric Modeling dialog closes and the plate model is displayed.
2. On the View ribbon tab, select the Display Whole Structure tool in the Tools group.

   ![Image of Parametric Modeling]

   The standard view is restored, displaying the hidden portions to the view.
3. (Optional) On the Select ribbon tab, select the All tool in the Beams group.

   ![Image of Select ribbon]

   Tip: It is not necessary to select the members in order to perform the next steps. However, this can serve as an easy way to identify the edges of the slab-wall interface when selecting the vertices.
4. On the Geometry ribbon tab, select the Wall/Slab Connection tool in the Structure group.

   ![Image of Geometry ribbon]
5. Starting with the two nodes at the base, select the four corner nodes of the wall in a clockwise order, clicking on the first selected node a second time to complete the boundary definition.

The Division along wall dialog opens.

Note: As the divisions along the base of the wall must be compatible with the slab density line, this value will control the meshing along the sides.

6. Click OK.
   The default value of 10 divisions is sufficient for this example.

7. On the Utilities ribbon tab, select the Plate Tools > Plate Connectivity tool in the Geometry Tools group.
   A message dialog opens indicating that no overlapping plates are found. This indicates also that the slab and wall are properly connected.
EX. Building Planner Workflow Example

This short tutorial will guide you through the creation of a small two-story concrete frame building using the Building Planner workflow.
EX. Create the model and plan details

1. On the Start page, select **New**. The New page opens to the **Model Info** tab.
2. Type **Building Example** in the **File Name** field and then select a **Location** to store the file.
3. Select the **Building** option for the **Type** of model.
4. Select **Metric** for the **Units**.

**Note:** You can use either system of units in the STAAD.Pro Analytical Workflow once you generate the analysis model. However, the Building Planner application only operates in metric units.

5. (Optional) Select the **Job Info** tab to add project member names, dates, project description data, etc. You can also associate your STAAD project with a ProjectWise Project here.
6. Click **Create**.

The STAAD.Pro window closes and the STAAD Building Planner application opens. The **Start** dialog opens.

7. Provide the project details:
   a. Type **Building Example** in the **Project** field.
   b. Type **Demo** in the **Client** field.
   c. Type your name or initials in the **Engineer** field.
   d. Type **2** in the **No. of Levels** field.
   e. Type **5 (m)** in the **Founding Depth** field.
This value is the distance from the top of foundations to the first floor.

8. Click **Create Project**.
   The **New Plan** dialog opens.

9. Enter in the plan details and assign it to the levels:
   a. Type 4 (m) in the **Height of Level Above** field.
   b. Click in the **Assign Levels** drop-down list and then click in the fields for both levels 1 and 2 such that **Plan1** is displayed there.
   This action assigns the typical plan to both levels.
   c. In the **Import Plan** group, select the **Create Plan Graphically** option.
   You will use the graphical interface to create a simple plan in this tutorial.
   Leave the remaining options in the dialog their default values.
10. Click Create Plan.
   The Slab Details (Rectangle) dialog opens.

   Proceed to the next set of steps to generate the slab.

**EX. Create the slab layout**

This procedure continues from the previous steps in which you created the model and plan details in building planner.

1. In the Slab Details (Rectangle) dialog, type 7 (m) in the Breadth (B) field.
   This updates the slab loading direction diagram in the dialog. Leave all other fields and options their defaults.
2. Click **OK**.
   A single slab section is added to the graphical view.

3. Select **Slab > Create Slab Rectangle**.

4. Click inside the existing slab near the top, left corner.
   A rectangular window is now pinned to the nearest corner and "rubber banded" to your mouse pointer.

5. Click at a point near where you want the opposite corner of the slab section placed.
   This should roughly be in line with the existing slab edge.
   The **Slab Details (Rectangle)** dialog opens. The same parameters from your first slab are entered.

6. Either:
   - click **OK**
   - or
   - press **<Enter>**
   The new slab section is added adjacent to the existing slab edge.

7. Repeat steps 5 and 6 to complete the 2 bay by 3 bay slab area.
Tip: You do not need to reselect the tool from the menu as it remains active after you create a slab.

Click the Save tool to save your progress so far.

**EX. Add the beams and columns**

1. Select Beam > Auto Beam.
   The Auto Beam Detail dialog opens.
2. Customize the beam properties to use:
   a. Type 0.30 (m) for the Internal Beam Breadth.
   b. Type 0.25 (m) for the External Beam Breadth.
   Leave the remaining parameters their default values.
3. Click **OK**.
   The beams are automatically added around the slab panel edges.
4. If the Select Beam to Break dialog opens, break the beams spanning 7 m.
   That is, such that the girder spanning horizontally on the screen is continuous.
5. Repeat step 4 if necessary.
6. Select **Column > Auto Column**.
   Square columns are automatically added at each beam intersection.

EX. Check for errors and align columns

1. Perform error checks:
   a. Select **Analysis > Slab Error Check**.
      This should result in no warnings or messages.
   b. Select **Analysis > Beam Error Check**.
      This should result in no warnings or messages.
2. Select **Analysis > Finalize Plan (with Continuity)**.
   A message dialog confirms the plan is finalized.
3. Select **Workspace > 3D Frame**.
   If the **3D View** window opens, close this window.
   **Note:** You are now in the frame workspace, which has different menu options.
4. Select **Assign > Column Sizing and Orientation**.
   The **Column Sizing** window opens.
5. Set the column offset so that the faces of the columns align with the faces of the exterior beams:
   a. Click Column C1 to select it (the top, left column).
   b. In the Column Offset And Beta Angle diagram, click corner 4 (the top, left corner).
   c. Click **Update Offset Data & Beta Angle**.  
      The column face is aligned to this point on the beams.

6. Repeat step 6 for each of the edge and corner columns, selecting the corresponding edge or corner for alignment.
7. Close the Column Sizing window.

EX. Assign lateral load data and generate the analysis model

1. Select Assign > Wind Parameters.
   The Wind Parameters dialog opens. Here you can select the appropriate Indian or American code for wind loads and assign parameters. For this example, you will accept the default parameters.
2. Select IS 875-1987 from the **Design Code** drop-down and then click OK.

3. Select **Assign > Seismic Parameters**.

   The **Seismic Parameters** dialog opens. Here you can select the appropriate Indian or American code for wind loads and assign parameters. For this example, you will accept the default parameters.
4. Select **Analysis > Generate Analysis File**. The **Space Frame Generation** dialog opens.

5. Click **Generate**. A warning dialog asks to overwrite the existing file, click **Yes**.

The STAAD Building Planner window closes and the analysis model opens in STAAD.Pro. All gravity loads, lateral loads, load combinations, and analysis commands have been added to the STAAD.Pro model. You can run the analysis in the Analytical Modeling workflow with no further actions necessary.

**EX. Steel Design Examples**

**EX. Connection Design Example**

This short tutorial presents an overview of design and detailing several steel connections. This example uses US Example no. 7, which is included with the installation of STAAD.Pro.
To start the Connection Design workflow

To open the example file in the Connection Design workflow, use the following procedure.

Using the Connection Design workflow requires a RAM Connection license. This license can incur additional cost to your organization.

1. a. Close any open model files in STAAD.Pro.
   b. On the Start page, check **RAM Connection** in the **Additional Licenses** panel.
      The **Additional License Selected** message opens to indicate that this can incur additional cost.
   c. Click Yes to activate this license for STAAD.Pro.
2. Open the file example file US.7. Modeling Offset Connections in a Frame.std in the **Analytical Modeling** workflow.
   This file is typically found in the
   C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\directory.
3. (Optional) On the **View** ribbon tab, **3D Rendering** tool in the **Windows** group.
   This view is useful to quickly identify the orientation of the columns with respect to the framing beam members. Here, it is evident that the beams and brace frame into the column flanges (rather than the webs).
4. Either:
   Select the **Run Analysis** tool in the **Analysis** group on the **Analysis and Design** ribbon tab.
or

Press <CTRL+F5>

The STAAD Analysis and Design dialog opens.

During the analysis (and design, if specified), an output file is generated. This file may contain selected input data items, results and error messages. Optional print specifications can be used to include additional information in the output file.

5. Click Done.

6. Select the Connection Design workflow.
   The RAM Connection - Validation dialog opens.

7. Click Close.

EX. To design the roof beam to column connections

1. Hold <Ctrl> and select both upper columns and the roof beam (members 3, 4, and 6).

2. On the Connection Design ribbon tab, select the Smart Connection tool in the Assign Connections group.
3. Select AISC 360-10 (ASD) as the Design Code. Leave all other options unchecked.

4. Select Clip Angle BCF (Clip Angle, Beam-Column(Flange)) from the connection types drop-down list.

5. Double-click DA BCF All bolted in the Available list. It is added to the Selected list.

6. Click OK. 
The RAM Connection - Validation dialog opens to display the design results overview.

7. Click Close. The connection design is added to the RAM Connection Input table.

**EX. To design the floor beam to column connection**

1. Hold `<Ctrl>` and select both the left column sections and the floor beam (members 1, 3, and 5).

2. On the Connection Design ribbon tab, select the Smart Connection tool in the Assign Connections group.

   ![Diagram of a floor beam to column connection]

   The Smart Connections dialog opens.

3. Select AISC 360-10 (ASD) as the Design Code. Leave all other options unchecked.
4. Select Unstiffened Seated BCF (UnStiffened Seated, Beam-Column(Flange)) from the connection drop-down list.

5. Double-click BCF Bolted in the Available list.
   It is added to the Selected list.

6. Click OK.
   The RAM Connection - Validation dialog opens to display the design results overview.

7. Click Close.
   The connection design is added to the RAM Connection Input table.

EX. To design the brace gusset plate connection

So far, you have selected members which form a joint for design. In this procedure, you will use some of the quick selection tools in the program which can be used to select all joints of a similar type.

1. On the Connection Design ribbon tab, select the Select Joints > Select all Column-Beam-Brace Joints tool in the Assign Connections group.
   Members 1, 2, 4, 5, and 7 are selected.

2. Hold <Ctrl> and then click the lower, left column section to remove it from the selection set.
   The lower end of the brace ends at a support so a separate connection design incorporating the base plate is needed.

3. On the Connection Design ribbon tab, select the Gusset Connections tool in the Assign Connections group.
   The Gusset Connections dialog opens.
4. Select AISC 360-10 (ASD) as the Design Code. Leave all other options unchecked.
5. Select Gusset Plate CBB (Gusset Plate, Column-Beam-Brace) from the connection types drop-down list.
6. Double-click the CBB_DW_CBF entry in the Available list. This is a Column-Beam-Brace connection, directly welded, at the column and beam flanges. It is added to the Selected list.
7. Click OK. The RAM Connection - Validation dialog opens to display the design results overview.
8. Click Close. The connection design is added to the RAM Connection Input table.

EX. To design the gusset base plate connection

1. Hold <Ctrl> and select the lower-left column segment and the brace (members 1 and 7).

3. Select AISC 360-10 (ASD) as the Design Code. Leave all other options unchecked.
4. Select Gusset Base Plate from the connection types drop-down list.
5. Click [>>] to include all options in the Selected list. In this case, there is only a single Gusset BP type.
6. Click OK.
   The RAM Connection - Validation dialog opens to display the design results overview.

7. Click Close.
   The connection design is added to the RAM Connection Input table.

EX. To change detailing of a connection

1. In the RAM Connection Input table, double-click the row for connection number 3 (connection BCF - N(3) - M(1,5)).

Tip: You can also use the Joint Cursor tool in the Connection Design ribbon tab to double-click on a joint in the View window.

The Connection Pad window opens. This window contains the details of the current connection design as well as a 3D rendering.

2. In the right details pane, select the Seat angle in the Unstiffened seated section.
   The default design is a relatively small seat angle and larger top angle.

3. Select an L40408 for the Seat angle section and then click OK.
The design, connection detailing, and drawing update immediately.

4. Click the **Results** tool to display the design checks report.

5. In the Report window, select the show Formulas tool.
   The report updates with the calculations for each check.

   **Tip:** You can export either format to a Microsoft Office Word document. Including formulas significantly increases the length of the report.

6. Select the **Exit** tool to close the report window.
7. Select the **Save** tool.
8. Click the **[X]** to close the **Connection Pad** window.
   The design is updated in the **RAM Connection Input** table.

**EX. To generate a report of the connection designs**

1. On the **Connection Design** ribbon tab, select the **Connection Report** tool in the **Reports** group.

   The **RAM Report Export** dialog opens.
2. Select the **Grouped by Identical Connections** options. The two BCF connections for the roof beam are grouped together.

3. Click **Select All**. Leave the other options their defaults: include Data Report, Results Report with Formula, and in a merged reports format.

4. Click **OK**. The report is generated and saved to a Microsoft Office Word document (*EXAMP07_report.doc*) in the same folder as the STAAD input file.

5. Click **OK**.

**Tip:** You can also add a summary table of the connection design results to your STAAD report.

**EX. Connection Tags Example**

This example demonstrates applying and checking connection tags.

**Connection Tag Data**

Use the **Copy to clipboard** button below to copy and paste this connection data into an empty text file and then save it as *Connection_Tag_Example.xml* to a convenient location.

**Tip:** The default location for connection tag data in STAAD.Pro can be found at `%LOCALAPPDATA%\Bentley\Engineering\STAAD.Pro CONNECT Edition\Default\Plugins\ConnectionTagLink`.

</Tags>
</ConnectionTagFile>

**Note:** This is an extremely short connection data example for the purposes of demonstration. A typical connection data file would contain a very large number of connection capacities for checking.

**EX. To open the example and load example connection data**

Copy and save the example connection tag data presented in the previous topic before proceeding.

1. Open the file example file **US.7. Modeling Offset Connections in a Frame.std** in the **Analytical Modeling** workflow.
This file is typically found in the
C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\US\directory.

2. On the Utilities ribbon tab, select the Connection Tags > Open Tab Specifications tool in the Tools group.

The Select Connection Tag File dialog opens.

3. Navigate to the Connection_Tags_Example.xml file and click Open.

This file can be found where you saved it in the previous topic.

EX. To assign the connection tag types to beam ends

1. Select both beams 5 and 6.
   
   Tip: Press <Shift+B> to display the beam numbers.

2. On the Beam Tools ribbon tab, select the Assign tool in the Connection Tags group.

   The Assign Connection Tags and New Connection Tag dialogs open.

3. In the New Connection Tag dialog, select the options to generate the tags:
   
   a. Select EM from the Select Tags drop-down list.
   b. Select both Start and End options for the Location.
   c. Click Assign.

   The dialog closes and the two tags are added to the Assign Connection Tags dialog, assigned to the members.

   Note: There are two tags generated, one for the beam start and another for the beam end.

4. Click Close on the Assign Connection Tags dialog.

EX. To check the connection tags

1. On the Utilities ribbon tab, select the Connection Tags > Check Tags tool in the Tools group.

   The Assign Connection Tags and Check Connection Tags dialogs open.

2. In the Check Connection Tags dialog:
   
   a. Check the option for the 1 - WIND LOAD load case.
   b. Click Check.

   The Connection Tag Check Results dialog opens.
3. (Optional) Click the Print tool to open the print Preview window, where you can save a copy of the connection tag results table.

EX. Interactive Concrete Design Examples

This is an example of using the interactive Concrete Design workflow to design an example concrete structure.

EX. BS8110 British Code Design Example

This example uses the STAAD.Pro UK example 9 model, which can be found in the STAAD.Pro installation folder at C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\UK.9. Modeling Slabs and Shear Walls Using Finite Elements.STD.

The following outlines the steps to create the model and element designs.

EX. BS8110 Model Setup

The following procedures are used to open an example model, select loads to add to a design envelope, setup up design briefs including code parameters, and add members to a design group.

EX. To open the example model in RC Designer

Before carrying out any specific design, first perform the following steps which are general to all the designs:

   
   This file is typically installed with the program in C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\UK\.
2. On the Analysis and Design ribbon tab, select the Run Analysis tool in the Analysis group.

This produces a set of analysis results required for design.

3. Select the Concrete Design workflow.

The model is opened in Concrete Design.

4. (Optional) Enter job information in the Job Information dialog for inclusion in reports.

EX. To create the envelope used in the beam design

1. Select the Design Layer | Envelopes page (on page 1202) in the page control found on the left side of the program window.
2. Click New Env. at the bottom of the Envelopes Table (on page 1204) to create a defined envelope of load cases and combinations.
   The New Envelopes dialog (on page 1204) opens.
3. Enter the name Envelope 1 in the E# field.
4. Click OK.
   The Define Envelopes dialog (on page 1205) opens, which allows the setting of which load cases and combinations are to be considered for Envelope 1.
5. De-select the option to Show Combinations Only.
   Primary load cases L1 and L2 are now displayed in the Load Cases list.
6. Click the >> button
   All the load cases and combinations L1, L2, and C3 are now included in the envelope E1.
7. Click OK to accept this definition.

EX. To create the design members

1. Select the Design Layer | Members Page (on page 1202) in the page control.
2. Either:

   Use the Elements Cursor tool (selected by default) to drag a box around the entire model.
   or
   Select Select > Select All.
3. Select Members > AutoForm Members to automatically create design members.

   Fifteen members are created.

   Note: The horizontal beams and corner columns have been created correctly, but the center columns have been formed into small segments (M8, M9, M10, M11 and M12, M13, M14, M15) which are not ideal physical members for design.
4. Select the Members Cursor tool.
5. Select these unconnected members (see note above) and press the Delete key.
6. Select the Elements Cursor tool
7. Select the four elements that make up the column on one side
8. Select Members > Form Member (on page 1150).
   A new, single member, MB, is created.
9. Repeat steps 6 through 8 for the four elements that form the column on the other side to form member M9.

EX. To create a floor slab

1. Select the Slabs Page in the page control.
2. Select the Side View tool to get an elevation view of the model.
3. Use the Select Plates tool (selected by default) to drag a window to select all the plates that form the top floor.
   Tip: Be careful not to select the plates that form the top of the shear wall.
4. Select Slabs > Form Slab.
   Tip: Note the details of the slab in the Slabs table (on page 1153) and confirm that it has been created with 32 plates and has no holes. If not, delete the slab definition and repeat steps 3 and 4 until the correct slab is created.

EX. To create a BS 8110 beam design brief

1. Select the Groups/Briefs Page in the page control.
2. Click New Brief at the bottom of the Design Briefs table (on page 1155).
   The New Design Brief dialog (on page 1156) opens.
3. Enter BS8110 Beam Brief in the B1 field.
4. Select BS8110 in the Design Code list.
5. Select Beam in the Design Type list.
6. Click OK.
   The BS8110 Beam Brief dialog (on page 1255) opens.
7. Select C40/50 for the Concrete Grade.
8. Select the Main reinforcement tab
10. Click OK.

EX. To create a BS 8110 slab design brief

1. Click New Brief at the bottom of the Design Briefs table (on page 1155).
   The New Design Brief dialog (on page 1156) opens.
2. Enter BS8110 Slab Brief in the B3 field.
4. Select Slab in the Design Type list.
5. Click OK.
   The **BS8110 Slab Brief** dialog (on page 1260) opens.
6. Select **C40/50** for the **Concrete** grade.
7. Click OK.

**EX. To create a beam design group**

1. Use the **Members Cursor tool** to select the five members that form the perimeter of the slab and the member that lies along top of the shear wall in the center of the model (M1, M2, M3, M4, and M5).
   
   **Tip:** Hold <CTRL> to add members to the selection set.
2. Click **New Design Group** on the **Design Groups table** (on page 1160).
   The **New Design Group dialog** (on page 1149) opens.
3. Enter **BS8110 Beam Group** in the **G1** field.
4. If **BS 8110 Beam** is not the selected **Design Brief**, then select it.
5. Click OK.
6. Double click the G1 group in the Design Group table.
   The **Group Member list** (on page 1160) opens for the selected Design Group.
7. Confirm that the design group contains the correct list of design members.

**EX. To create a column design group**

1. Use the **Members Cursor tool** to select the six members that form the columns of the slab, including the two internal columns that edge the internal shear wall (M6, M7, M8, M9, M16, and M17).
   
   **Tip:** Hold <CTRL> to add members to the selection set.
2. Click the **New Design Group** button on the **Design Groups table** (on page 1160).
   The **New Design Group dialog** (on page 1149) opens.
3. Enter **BS8110 Column Group** in the **G2** field.
4. Select **BS 8110 Column** in the **Design Brief** list.
5. Click OK.
   The **Group Member list** (on page 1160) opens for the selected Design Group.
7. Confirm that the design group contains the correct list of design members.

**EX. To create a slab design object**

1. Select the Slabs tab at the top of the **Design Groups table** (on page 1160).
2. Click the New Design Slab button.
   The **New Design Slab dialog** (on page 1162) opens.
3. Enter **BS8110 Slab** in the **SD1** field.
4. If **BS 8110 Slab Brief** is not the selected **Design Brief**, then select it.
5. Select 1 in the **For Slab** list.
6. Click OK.

The model is now ready for performing design.
Tip: Now is a good time to save your model if you haven't already done so.

EX. BS8110 Beam Design

The model is ready for the beams in Design Group 1, G1: BS8110 Beam to be designed.

EX. To design the beam members in the concrete member mode

1. Select the Concrete Member mode in the page control. The Concrete Member | Summary page opens.
2. Ensure that the current design group is **G1: BS8110 Beam** and, if not, select it from the drop list on the Page/Mode Automatic toolbar (on page 1198). Note how Members M4 and M5 are identified as two spans in the Beam Group Summary and Beam Spans tables.
   Tip: This can changed by changing supports definition of the nodes in the on the Beam Spans table (on page 1177) Supports tab.
3. Select the Concrete Member | Design Page in the page control. The Design Options dialog (on page 1168) opens.
   Note: Members in the current design group that can be designed are automatically included, but some can be removed if no design is needed.
4. Click Design. All five members are displayed in green and the Summary table (on page 1187) shows the status for parts of all five beams as OK.

EX. To view the reinforcement layout for member 4

1. Select the Concrete Design | Main Layout Page in the page control.
2. Select **M4** (Member 4) from the design group members drop list found on the Page/Mode Automatic toolbar (on page 1198). The reinforcing details and moment envelope diagrams update for this member.
3. In order to see the full extent of the beam, drag the horizontal separator bar below the elevation view of the beam up until it looks like the following:
EX. To view the calculations

2. On the Items tab, select Design Detail in the Available list and move it to the Selected list by clicking the > button.
3. Select the Members tab.
4. Click the << button to un-select all the members.
5. Select Member 4 and click the > button to move it to the selected side.
6. Click **OK** to accept this Report Setup.
7. Select **File > Print Preview** to view the resulting report.
   The **Print Preview window** (on page 1115) opens.

The detail calculations will be displayed approximately on page 5 on a report of 14 pages:
Application Examples

EX. Interactive Concrete Design Examples

Member M4 Span 1
Detailed BS8110 Design Requirements

Section Property: 200 x 299
Span Length = 6.000 m Rectangular section
Width = 300 mm Depth = 300 mm
Covers: Top = 30 mm Bottom = 30 mm Side = 30 mm

Member M4 Span 1
Detailed BS8110 Main Reinforcement

Hogging: at 0.000 m from the start of the member

Moment applied to section
Effective depth of tension reinforcement
Depth to compression reinforcement
Redistribution < 10%, hence

\[ K = \frac{M}{bd^2 f_y} \]

\[ K \leq K_c \text{ hence compression steel not required.} \]

\[ z = d \left( 0.5 + \left( 0.25 \cdot \frac{K_c}{K} - \frac{K}{0.9} \right) \right) \leq 0.95d \]

\[ A'_{w} = \frac{0.87 f_z}{M} \]

Tension Bars provided = 2H16
Actual area of tension reinforcement
Minimum area of tension reinforcement
Maximum area of tension reinforcement
Actual% of tension reinforcement

4943 User Manual
**EX. BS8110 Column Design**

The model is ready for the columns in Design Group 2, G2: BS8110 Column to be designed.

**EX. To design the column members in the concrete member mode**

1. If you are not still in the Concrete Member mode, select it in the page control.
2. Select **G2: BS8110 Column** as the current design group from the drop list on the Page/Mode Automatic toolbar (on page 1198). The Concrete Member | Summary page (on page 1207) opens.
3. Select the Concrete Member | Design page (on page 1207) in the page control.
   The Design Options dialog (on page 1168) opens.

   **Note:** Members in the current design group that can be designed are automatically included, but some can be removed if no design is needed.

4. Click the **Design** button to design all six members.

   **Note:** This loading is not substantial and thus results in a Design Messages dialog which suggests that though these are axially loaded members, they are subject to greater bending moments and should be considered as beams. However, they will suffice for this example.

   All six members should be displayed in green and the Summary table (on page 1187) shows the status for parts of all six columns as OK.

**EX. To view and edit the reinforcement layout for member 6**

1. Click on the Concrete Member | Main Layout page (on page 1207).
2. If it is not already selected, select Member 6 from the drop-down of members in the current design group.
   The initial design produced an arrangement with the nine T16 bars in the locations shown in the diagram above. It is possible to replace each of the bars in the center of each face of the column with two smaller T8 bars.
   The Main Reinforcement window displays a force diagram, reinforcement elevation, and reinforcement section of the current design.
3. Right-click anywhere on the cross section (right pane).
4. Select Edit Bar Cage from the pop-up menu.
   The M# Bar Positions dialog (on page 1181) opens.
5. Set the distance for the Top and Side bars to 3.0cm
6. Reduce the size to TBs by clicking in the Size cell and selecting 8 from the drop-down list.
7. Click the Apply button.
   The bar arrangement diagram is updated.
8. Select **Design > Design Now** to check this arrangement.

    **Note:** While the same warnings appear about the small amount of axial load, the design shows that the arrangement is adequate.

**EX. To view the calculations**

1. Select **File > BS8110 Report Setup**.
2. On the Items tab, select Design Detail and move it to the Selected list by clicking the > button.
3. Select the Members tab.
4. Click the << button to un-select all the members
5. Select Member 6 and click the > button to move it to the selected side.
6. Click the OK button to accept this Report Setup.
7. Select **File > Print Preview** to view the resulting report.

   The detail calculations will be displayed approximately on page 2 on a report of 3 pages.

**EX. BS8110 Slab Design**

The model is ready for the slab SD1: BS8110 Slab to be designed.

**EX. To view displacement patterns in the concrete slab mode**

1. Select the Concrete Slab mode in the page control.

   The **Concrete Slab | Summary page** (on page 1212) opens.

   **Note:** This model only contains a single slab. If it contained more than one, then the required slab should be selected from the toolbar drop list.

2. Select the **Concrete Slab | Displacements page** (on page 1213).
3. Select **Results Line > Unconstrained**.
4. Select **Result Line > Create**.
   The mouse pointer changes to a Result Line drawing cursor in the slab diagram.

5. Click near the top center of the slab.
   A dashed line connects this point to your mouse pointer, indicating where the result line will placed.

6. Click a second point near the bottom center to complete the result line.
   The result line is drawn as a solid, black line with an arrow indicating the positive direction along the line.
   The Result Line Graph and table display the displacement along this line.

**EX. To define slab design regions**

1. Click on the **Concrete Slab | Regions** page.
   The slab defaults to a single boundary.

2. Select **Regions > Draw Boundaries**.
   The mouse pointer change to a Draw Regions cursor in the slab diagram.

3. Click the center node (top of the middle column) on the left-hand side of the diagram.
A dashed line connects this point to your mouse pointer, indicating where the region boundary will be placed.

4. Click the center node (top of the second middle column) on the right-hand side of the diagram. Two regions are created, one on either side of the newly created boundary line. The Regions table (on page 1166) indicates the details for each region, including the orientation.

5. Rotate the axes of region 1 by changing the orientation to 90 degrees in the Regions table.

**Note:** The orientation angle is taken counter-clockwise (i.e., anti-clockwise).

6. Select the Concrete Slab | Design page.
   The Design Options dialog box (on page 1214) opens.

7. Click the Design button to perform the design.
   The slab diagram displays a contour of the Spacing in the X direction along the top slab surface.

8. Select Bottom:Y direction and the Reqd Steel result in the toolbar.
   This will show a contour line pattern. The contour lines can also be displayed as filled to aid in viewing results.

9. Either:
   Select View > Diagram.
or

Right click on anywhere on the diagram and select **Diagram**... from the pop-up menu.
The **Diagrams dialog box** (on page 1144) opens.

**10.** On the Design Contour tab, select the option for **Filled** style and then click **OK**.

**EX. To print a design report**

1. **Select File > BS8110 Report Setup**...
The **BS8110 Report Setup** dialog box (on page 1110) opens.
2. **Confirm that the report contains the items:**
   - Job Information
   - Slab Brief Detail
   - Slab Information
   - Region Information
   - Design Information
3. **Click OK**
4. **Select File > Print Preview.**
The report is fitted on approximately two pages, with the second page containing the design results.

**EX. Advanced Concrete Design Tutorial**

**Getting Started**

STAAD Advanced Concrete Design is performed using the RCDC application, which is installed separately from STAAD.Pro. This program can be launched from the STAAD.Pro Building Designer mode or as a standalone application.

RCDC is a highly automated design tool for concrete building structures. This tutorial guides you through the process of designing the elements in a concrete building. It will also indicate where to change the design settings to customize design and detailing to meet the requirements of your project or organization.

**Tutorial File**

This tutorial uses example files that are installed with STAAD.Pro V8i. However, you will be making changes to this example file so you may wish to make a backup copy to preserve the example as installed with STAAD.Pro. A copy of the original input file is also included as **Appendix A** (on page 4979) of this tutorial.

**Starting in STAAD.Pro**

This example includes a fully modeled concrete structure, including loads. The modeling and application of loads per a building code specification are outside the scope of this tutorial. Refer to the STAAD.Pro help contents for additional information.
Using RCDC as a Standalone Application

You can also use RCDC as a standalone application for concrete design. You will still need to have a analytical model created in STAAD.Pro for the basis of the physical model as well as for analytical results.

Design and detailing of foundation elements such as footings and pilecaps must be performed by starting RCDC as a standalone application and creating a project associated with an analytical model.

To open the model and generate analysis

Tip: It is recommended that you first make a backup copy of all files with the name Typical Ground +3 Story Building in the C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Building Planner\folder. You can do this using the Archive feature (on page 2272) in STAAD.Pro.

1. Open the STAAD input file
   C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Building Planner\Typical Ground +3 Story Building.std

   Tip: If you have a ProjectWise Project you want to associate with this input file, you can do so. This is not necessary, though, for this tutorial.

2. (Optional) On the File ribbon tab Info tab, add job information:
   - type Tutorial in the Job field
   - type your organization’s name in the Client field
   - type your initials in the Engineer field

3. Either:
   - on the Analysis and Design ribbon tab, select the Run Analyze tool in the Analysis group
   - press <Ctrl+F5>

   The analysis is performed.

4. Select the Stay in Modeling Mode option and click Done.
5. Select the Building Planner workflow. The STAAD Building Planner window opens.

The STAAD Building Planner will be used to layout the structure.

To create a building model from floor plan

In order to demonstrate column design in RCDC, you will use the Building Planner model rapidly model a building from a single floor plan.

1. Select the Frame | Geometry page.
2. Click Edit in the Level Details dialog. The Level Information dialog opens
3. Type 6 (m) in the Height cell for row No 0-1 and press <Enter>.
4. Click Add Level and then click Yes in the confirmation dialog. A new row is added representing a new level.
5. Select Plan1 from the Plan drop-down list for the second level. Leave the default heights and other values for this level.
6. Click OK.
7. In the Level Details dialog, click Generate Model and then click Yes to confirm you want to update the STAAD input model. The Space Frame File Generation dialog opens.
8. Click **Generate**.
   For this tutorial, you will use the default settings, load settings, and building type. Refer to the STAAD.Pro User Interface help for details on these settings.
   The new input file is generated and opened.

9. Either:
   - select **Analyze** > **Run Analysis**
   - or
   - press <Ctrl+F5>
   The analysis is performed.

10. Select the **Stay in Modeling Mode** option and click **Done**.

To add a shear wall

To add a shear wall along one side of the elevators, do the following.

For the purpose of this tutorial, you will only add a single shear wall. In a typical building, other shear walls would be present.

1. In the Building Planner mode, select the **Frame | Shear Wall** page.
2. In the **Shear Wall Details** dialog, click **Edit**.
3. Click on column C31 and then on C32.
The Define Shear Wall dialog opens.

4. Click OK.
   For this tutorial, use the default thickness. The shear wall is added on both levels using this plan by default.

You have now finished all the necessary modifications to this example for this tutorial. The next sections cover the design and detailing of structural elements using RCDC.

**Slab Design**

This section of the tutorial demonstrates how to design and detail a slab, including openings and stairs.

Slab continuity is based on edge conditions where are automatically determined by the program. You can manually change the end conditions of a slab. You can also change a slab to a cutout, raised slab, or depressed slab which also affect the edge conditions.

Slab properties are imported from the analysis model where specified. The program will evaluate missing properties (e.g., slab thickness) during design when not specified.

To start the slab design

**Tip:** When you import STAAD.Pro model data into RCDC, grids are automatically detected and assigned. You can manually edit both the exact locations of grids as well as grid labels in RCDC for drawing generation.

1. In the top-right dialog, select **Level:1** from the drop-down list and then click **Design Slab**.
RCDC opens and the **New Project** dialog opens.

2. Enter the project data:

![New Project dialog](image)

- **a.** Type **Tutorial** in the **Project** field.
- **b.** (Optional) Type **Client** and **Engineer** name.
  
  This information is used as the header for all reports. It will be automatically imported from the STAAD.Pro input file Job Information block if available.
- **c.** Select **EN 02 - 2004** from the **Design Code** drop-down list.
  
  This tutorial uses the Eurocode. However, you can select any available code. Just note that some design settings and features may vary based on the code selection made here.

The slab edges are automatically detected and continuity is established.
3. Either:

select the **Design Parameters** tool

or

select **Settings > Design Parameters**

The **Design Settings** dialog opens.
4. In the Available Rebar list, clear the check mark by 25 (mm). This tutorial will limit the rebar size.

   **Note:** All other design settings are left as their defaults, but you can make many design and detailing changes here.

5. Click **OK**.
6. Either:

   select the **Crack Width Setting** tool

   or

   select **Settings > Crack Width Settings**
   
   The **Crack Width Settings** dialog opens.
7. Select the **Perform Check** option in the **Crack Width** group.

   **Note:** Leave the Permissible Crack Width as the default value and leave the Perform Check option in the Initial Thermal Cracking group unchecked for this tutorial.

8. Click **OK**.

   **To specify elevator openings**

   Since the analysis model does not contain openings in the slab, you can add those in RCDC.

   **Note:** RCDC can design and detail concrete stairs with the slab. Do *not* create an opening for the stairs if you plan to use this feature. Refer to the RCDC help topic **Slab > Staircase Section** for details on this feature.

1. In the Design Data table, select row 19 (for Slab 18).
   The slab is highlighted in the Slab Layout view window.
2. Do either of the following:
   - select **True** in the **Is Cut Out** cell for this row in the table
   - or
   - right-click on the slab in the view window and select **True** from the **Is Cut Out** drop-down in the pop-up menu
The slab is now marked as a cutout.

3. Select Modify > Re-evaluate Slab continuity.

**Note:** This will change the continuity of surrounding slabs. If you do not perform this step, you will be prompted to automatically re-evaluate the continuity before performing an autodesign.

To perform the design

Slabs in RCDC are designed for the **Imposed Load** and **Live Load** values input for each slab on the **Design Data** table. These values are imported (along with thickness, etc.) from the slab parameters specified in STAAD.Pro Building Planner mode.

1. Either:
   
   select the **Autodesign** tool.

   or

   select Design > Autodesign.

   A message dialog opens confirming you want to proceed since the continuity must be reevaluated if you have not already done so.

2. If you did not previously reevaluate the continuity, click **Yes**.

   The Design Output page opens.

   A warning message opens stating that two of the slabs have failed the design checks. The same slab is marked with a red row number in the table.

3. Select the row for the first failed slab (row 13, S24) in the table and then either:

   select the **Design** tool.

   or

   select Modify > Design

   or

   right-click and select Design from the pop-up menu
The **Design Slab** dialog for this slab opens at the bottom of the program window.

4. Type 325 (mm) in the **Thickness** field in the **Design Parameters** group.

5. Select the **Design** tool in the **Design Slab** dialog.
   The slab now passes the design checks.

6. Select the **Accept** tool to update the design with the changes.

7. Repeat steps 3 through 6 for S17 (row 24) with a thickness of 200 (mm).

To generate construction and detail drawings

1. Generate a GA drawing for the slab:
   a. Select **Reports > General Arrangement Plan**.
      The **GA Drawing** view window opens.
   b. Click the **Save** tool in the view window.
   c. Type **Sample_Slab_GA.dxf** and click **Save** to save the GA drawing as a DXF file.

2. Generate a schedule:
   a. Either:
      select the **Text Schedule** tool
   or
      Select **Reports > Text Schedule**.
      A dialog opens to ask if you want to group similar slabs.
   b. Click **Yes**.
      The **Text Schedule** view window opens.
   c. Click the **Save** tool in the view window.
   d. Type **Sample_Slab_Sched.dxf** and click **Save** to save the schedule as a DXF file.

3. Generate the reinforcement layout drawings:
   a. Either:
      select the **In-Plan Detailing** tool
   or
      Select **Reports > In-Plan Detailing**.
      The Top Reinforcement and Bottom Reinforcement drawings open.
   b. Click the **Save** tool in the view window.
   c. Type **Sample_Slab_TopReinfPlan.dxf** and click **Save** to save the schedule as a DXF file.
   d. Repeat steps 4b and 4c to save the bottom reinforcement plan as **Sample_Slab_BotReinfPlan.dxf**.

4. Generate a bill of quantities:
   a. Either:
      select the **Bill of Quantities** tool
   or
      Select **Reports > Bill of Quantities**.
      The **Bill Of Quantities** dialog opens.
b. Select the BOQ Summary option.
c. Select € - Euro from the Currency drop-down list.
d. Type 90 (€/m$^3$) for Grade C20/25 concrete and 4 (€/kg) for Grade Fy420 steel. Type 8 (€/m$^2$) for the Shuttering value.
e. Click OK.
   The BOQ Summary opens.
f. Either:
   - click the Print tool to print out a copy of this report
   - or
   - click the Save tool to save an HTML copy of this report

To generate design calculation reports

1. Either:
   - select the Design Summary tool
   - or
   - select Reports > Design Summary
   The Slab Design Summary opens.
2. Either:
   - select the Design Calculations tool
   - or
   - select Reports > Design Calculations
The Select Slabs dialog opens.
3. Check the boxes for S1 and S12.
   For this tutorial you will only output the detailed design for two slabs. You can check the All Slabs option to include the full design report.
4. Click OK.
   The Slab Design opens.
5. Either:
   - Click the Print tool to print out a copy of this report
   - Click the Save tool to save an HTML copy of this report

To save the project and exit
1. Either:
   - Select the Save tool (on the main program toolbar)
   - Select File > Save
   The Save As dialog opens.
2. Type Sample1_Slab_tutorial.rcdx in the filename and click Save.
   RCDC closes and you are returned to STAAD.Pro.

RCDC Settings Files
When you save your project in RCDC, in addition to the project file (.rcdx) a project settings file is also created (.rcps). You can select File > Import Project Settings to open the project settings for a previous project once you have established project or office standards you want to re-use.

Beam Design
This section of the tutorial demonstrates how to design and detail continuous concrete beams.
RCDC will automatically look for continuous beam members in the STAAD model and group these as a single physical beam. This way if you have a beam which continuous through columns or one which was sub-divided into STAAD.Pro to facilitate support of a transverse member, it will be designed as a single beam entity in RCDC.
In this example, you will use most of the default values for all designs.

To start the beam design
In STAAD.Pro, ensure you are on the Frame | Design page in the Building Planner mode.

   **Tip:** When you import STAAD.Pro model data into RCDC, grids are automatically detected and assigned. You can manually edit both the exact locations of grids as well as grid labels in RCDC for drawing generation.

1. In the top-right dialog, check the Level :1 option and then click Design Beams.
RCDC opens and the New Project dialog opens.

2. Enter the project data and select the design code:

   a. Type Tutorial in the Project field.
   b. (Optional) Type Client and Engineer name.
      This information is used as the header for all reports. It will be automatically imported from the STAAD.Pro input file Job Information block if available.
   c. Select EN 02 - 2004 from the Design Code drop-down list.
      This tutorial uses the Eurocode. However, you can select any available code. Just note that some design settings and features may vary based on the code selection made here.

The beam continuity is automatically detected as the analytical model data is read.

3. Either:

   select the General and Reinforcement Settings tool
   or

   select Settings > General and Reinforcement Settings

The General and Reinforcement Settings dialog opens.
4. In the **Rebar** list, clear the check mark by both 32 (mm) and 40 (mm). The initial design will be evaluated using smaller size bars where possible.

   **Note:** All other design settings are left as their defaults, but you can make many design and detailing changes here.

5. Click **OK**.

   **Note:** There are numerous other detailing and drawing settings in RCDC that allow you to customize the concrete detailing for your client or organization’s needs. For details on these options, refer to the RCDC help by pressing <F1> or selecting **Help > Contents**.

To specify load cases and combinations

1. Select **Settings > Basic Load Cases**
   The **Basic Load Cases** dialog opens.

2. (Optional) If the **Load Type** selection is not already specified for each load case, select it from the drop-down list:
3. (Optional) If both loads are not already added to the Primary Load Cases list, click the \([+]\) button when a load case is selected in the Analysis Load Cases list to add it.

   **Note:** You can import previously saved load cases and combinations to use by clicking the **Import Load Cases & Combinations** button and selecting an .ldsx file. Refer to the following steps on how to create a load settings file.

4. Click **OK**.
   The **Load Combinations** dialog opens.

5. Click **Add From Analysis**.
   The load combination from the analysis file is added for strength design checks.

6. Add the load combination for use in evaluating crack width:
   a. Select the **Crack Width** tab.
   b. Click **Add From Template > For Regular Structure**.
      A service level load combination is added from the RCDC load combinations template.

   **Note:** Typically, a different (service level) load combination is used for evaluating crack widths. If you already have appropriate service load combinations in your analytical model, you can add those instead and select them for use here.

   c. Check the options for **Crack Width** and **Stress Limit** in the load load combination in the table.

7. Export the load cases and combinations for later use:
   a. Click **Export Load Cases & Combinations**.
      The **Save As** dialog opens.
   b. Type **Sample1_Loads** and click **Save**.

8. Click **OK**.

**To split beam group at staircase**

1. Select the **Design Input | Beam Continuum** tab.
2. Select the third beam group in the chart.

   **Note:** The beams on grid line 6 are highlighted in the Layout view.

3. Right-click on the blue box labeled C17 (column 17) and select **Split Group** from the pop-up menu.
   The beam group is split into two physical members at this location.

4. Select the **Design Input | Design Grouping** tab.
5. Select G19 in the table or click on the newly created beam group in the Layout view.
6. Type **-900** in the **Top** field for both beam segments in G19 (B14 and B15).
   This represents a top of beam elevation of 0.9m below the floor elevation.

**To perform the beam design**

1. Either:
   select the **Autodesign tool**

   or
select Design > Autodesign.

An exceptions dialog opens indicating that two beams have failed the design checks.

2. Click OK.

3. Either:

   select the Failure Diagnostics tool

or

select Reports > Failure Diagnostics

The Failure Diagnostics tab opens. The table indicates that many beams are failing due detailing checks.

4. Evaluate some options for beam group 2:

   a. Select any of the beam segments in G2 in the Design Output table.

      The beam segments in this group are marked with a red tag to indicate the group failed one or more checks.

   b. Either:

      select the Design tool

or

select Modify > Design

The Redsign Grp dialog opens at the bottom of the program window.

   c. Type 3 in the Bar Layers at Top field.

   d. Select the Redesign tool in the Redesign Grp dialog.
The beam now passes design and crack width checks.

**e.** Select the **Accept** tool.

The Design Output table now shows green for the G2 beam indicating it passes.

5. Repeat step 4 to redesign G7 with 3 layers of top bars as well. Optionally, you can use the **UnLock** tool to unlock the current design and then change the initial settings to use larger reinforcement sizes.

6. Review the detailing on the demand and capacity curve for a beam:

   a. Select beam group G1 and either:

      - select the **Detail** tool

      or

      - select **Modify > Detail**

      or

      right-click and select **Detail** from the pop-up menu

   The Redtail dialog opens at the bottom of the program window.

   b. Click-and-drag your mouse cursor over the beam subdivisions starting at 0.75L of the first beam span in G1.

   c. Right-click and select **Detail** from the pop-up menu

   The Top Steel pop-up dialog opens.

   d. Delete the N1 value for layer 4 and then select the empty value for D1 for the same layer.

   This will remove the fourth layer of bars from the top steel in this segment, creating a new reinforcement detail for the selected segment.

   e. Click **OK**.

   The section of the capacity curve for the top steel updates to reflect the detailing change.
f. Click Cancel.

**Tip:** You can use select the beam segments or entire reinforcement zones by their labels just below the diagram. You can copy and paste reinforcement details between zones or selections.

7. (Optional) Check for any resized beams during design by selecting **Reports > Beam Size Changed**.
A report including any resized beams during design opens. For this example, none of the beams were resized.

To generate beam schedules and drawings

1. Generate a text schedule of beam reinforcement:
   a. Either:
      select the **Text Schedule** tool
   or
      Select **Reports > Text Schedule**.
      The **Schedule Type** dialog opens.
   b. Select the **Type 1** option.
   c. Select the **Group Beams** option.
   d. Click **OK**.
      The **Text Schedule** view window opens.
   e. Click the **Save** tool in the view window.
   f. Type **Tutorial_Beam_Sched.dxf** and click **Save** to save the schedule as a DXF file.

2. Generate an elevation for any beam group:
   a. In the **Design Output** table, right-click on any beam group and select **Quick Elevation** from the pop-up window.
      The elevation drawing for this beam group opens in the lower section of the program window.
   b. (Optional) Select the **Save** tool in the **Elevation** view to save this view as a DXF file.
   c. Select the **Cancel** tool to close the elevation view

3. Generate the elevation and sections for a beam group:
   a. Either:
      select the **Elevation and Section** tool
   or
      Select **Reports > Elevation and Section**.
      The **Select Beams** dialog opens.
   b. Select group **1.B1-B2-B3-B4** in the beams list.
   c. Select the following Draw options:
Tip: You can modify the drawing and detailing options by clicking the **Detailing & Drawing Settings** button (also by selecting **Settings > Detailing & Drawing Settings** before using this tool). You can also customize rebar mark styles from this dialog.

d. Click **OK**.
The Elevation for the selected beam group opens.
e. Click the **Save** tool in the view window.
f. Type **Tutorial_Beam_Sched.dxf** and click **Save** to save the schedule as a DXF file.

4. Generate a bill of quantities:
a. Either:
   - select the **Bill of Quantities** tool
   - or
   
   Select **Reports > Bill of Quantities**.

   The **Bill Of Quantities** dialog opens.

   ![Bill Of Quantities dialog](image)

   b. Select the **BOQ Summary** and **Reinforcement Type Wise** options.
   c. Select **€ - Euro** from the **Currency** drop-down list.
   d. Type 90 (€/m³) for Grade C20/25 concrete and 4 (€/kg) for Grade Fy420 steel. Type 8 (€/m²) for the Shuttering value.
   e. Click **OK**.

   The **BOQ Summary** and **BOQ Detailed - Reinf Type Wise** tabs open.
f. Either:
click the **Print** tool to print out a copy of this report

or

click the **Save** tool to save an HTML copy of this report

5. Generate bar bending schedule:

   a. Select **BBS > Generate BBS**.
      The **Generate BBS** dialog opens.

   b. Select **1.B1-B2-B3-B4** and **2. B5-B6-B7-B8-B9** in the list of beam groups.
   c. Select the **Continuous** option in the **Rebar Numbering** group.
   d. Select both the **Drawing** and **Spreadsheet** options in the **Schedule Format** group.
   e. Click inside the file path field, type **Tutorial_Beam_BBS** in the **Save As** dialog that opens, and then click **Save**.
   f. Click **Generate**.
      The BBS opens containing a text schedule of the bar bending schedule. If you have Microsoft® Office Excel® installed (or another spreadsheet program capable of opening .xslx format spreadsheet files), the spreadsheet of the bar bending schedule opens.
   g. Close your spreadsheet application.
   h. Click the **Save** tool in the view window.
   i. Type **Tutorial_Beam_BBS.dxf** and click **Save** to save the schedule as a DXF file.

To generate beam design calculations

1. Either:
   - select the **Design Summary** tool
   or
   - select **Reports > Design Summary**
      The **Design Summary** opens.
2. Either:
select the Design Calculations tool

or

select Reports > Design Calculations
The Select Beams opens.

For this tutorial you will only output the detailed design for two beam groups. You can check the All Beams option to include the full design report.

4. Click OK.

5. Either:
   click the Print tool to print out a copy of this report
   or
   click the Save tool to save an HTML copy of this report

To save the project and exit

1. Either:
   select the Save tool (on the main program toolbar)
   or
   select File > Save
   The Save As dialog opens.

2. Type Sample1_Beam_tutorial.rcdx in the filename and click Save.

   RCDC closes and you are returned to STAAD.Pro.

Column and Wall Design

This section of the tutorial demonstrates how to design and detail continuous concrete columns.
RCDC will make continuous physical columns out of collinear analytical columns modeled in the Building Planner mode in STAAD.Pro.

To start the column design

In STAAD.Pro, ensure you are on the Frame | Design page in the Building Planner mode.

Tip: When you import STAAD.Pro model data into RCDC, grids are automatically detected and assigned. You can manually edit both the exact locations of grids as well as grid labels in RCDC for drawing generation.

1. In the top-right dialog, click Design Columns.
RCDC opens and the **New Project** dialog opens.

2. Enter the project data:

   a. Type **Tutorial** in the **Project** field.
   
   b. (Optional) Type **Client** and **Engineer** name.
      
      This information is used as the header for all reports. It will be automatically imported from the STAAD.Pro input file Job Information block if available.
   
   c. Select **EN 02 - 2004** from the **Design Code** drop-down list.
      
      This tutorial uses the Eurocode. However, you can select any available code. Just note that some design settings and features may vary based on the code selection made here.

   The column continuity is automatically detected as the analytical model data is read.

3. Either:

   select the **Reinforcement Settings** tool 🛠️
   
   or
   
   select **Settings > Reinforcement Settings**

   The **Reinforcement Settings** dialog opens.
4. In the Rebar list, clear the check mark by both 32 (mm) and 40 (mm).
   The initial design will be evaluated using smaller size bars where possible.

5. Click OK.

Note: There are numerous other detailing and drawing settings in RCDC that allow you to customize the concrete detailing for your client or organization’s needs. For details on these options, refer to the RCDC help by pressing <F1> or selecting Help > Contents.

To import load cases and combinations

In this procedure, you will import the load settings file you saved when designing the beams (on page 4963).

1. Select Settings > Basic Load Cases.
   The Basic Load Cases dialog opens.

2. Click Import Load Cases & Combinations.
   The Open dialog opens.

3. Select the file Sample1_Loads.ldsx and then click Open.
   If you saved this file under a different name or in a different location, locate and select the file you created in the previous section.
   The previously selected load cases are added to the Primary Load Cases list.

4. Click OK.
   The Load Combinations dialog opens. The previously selected load combinations from the analysis model are also already added.
5. Click OK.

To perform the column design

1. Either:
   - select the Autodesign tool
   or
   - select Design > Autodesign.
   The Failed Columns Dialog dialog opens indicating that two columns have failed the design checks.

2. Click OK.

3. Either:
   - select the Failure Diagnostics tool
   - select Reports > Failure Diagnostics.
   The Failure Diagnostics tab opens. The table indicates that the two beams have failed a detailing check.

4. Evaluate some options for column 12:
   a. Select the row for column C12 from 6m TO 12m in the column design table.
      This column is marked with a red tag to indicate it failed one or more checks.
   b. Either:
      - select the Redesign Section tool
      - select Modify > Redesign Section
      or
      right-click on the column row and select Redesign Section from the pop-up menu.
      The Redesign Column dialog opens at the bottom of the program window.

   c. In the Dia list, select 20 (mm) and then in the Bars list select 3#.
      This will place 20mm bars in groups of three in the section.
   d. Click on any of the corner bars in the cross section.
      The color-coded size of the grouped bars are added to each corner.
e. Repeat steps 4c and 4d to add single (1#) 20mm bars along the faces.

Note: Once you select number of bars, you only need to click twice in the section to update all the face bars.

f. Select the Redesign tool in the Redesign Grp dialog. The column now passes design and detailing checks.

g. Select the Accept tool. Right-clicking on a wall and selecting Redesign Section allows you to graphically detail a wall section in the same manner. Try this with W1 in the Column Design table as an extra exercise.

The Design Output table now shows green for the G1 beam indicating it passes.

5. Repeat step 4 to redesign the other failing column (C23).
6. Right-click on the second level column 12 (C12: 6m TO 12m) and select Interaction Surface from the pop-up menu. The Interaction Surface dialog opens.
7. Review the interaction surface:
   - **Options**
     - To display the interaction at critical points for a load combination
     - To view the interaction at any point along the column height
     - To control the view of the interaction surface
   - **Description**
     - select that combination from the table
     - drag the slider to a specific load value
     - use the view controls at the top of the interaction surface view window

8. Click the X in top-right to close the Interaction Surface window.

To generate column schedules and drawings

1. Generate a text schedule of column reinforcement:
   - a. Either:
      - select the Text Schedule tool
      - or
      - Select Reports > Text Schedule > Type 1 (Ductile) Section.
      - The Text Schedule view window opens.
   - b. Click the Save tool in the view window.
   - c. Type Tutorial_Column_Sched.dxf and click Save to save the schedule as a DXF file.

2. Generate detail drawings of columns:
Application Examples
EX. Interactive Concrete Design Examples

a. Either:
   select the **Detailed Drawing** tool
   or
   Select **Reports > Detailed Drawing**.
The **Select Columns** dialog opens.
b. Select 0m to 12m for the range of heights.
c. Select C1 and W1 in the columns list.
d. Click **OK**.
The **Detailed Drawing** opens with the Column and Wall Schedule.

![Detailed Drawing Screenshot]

**e.** Click the **Save** tool in the view window.

**f.** Type `Tutorial_Col_Detail.dxf` and click **Save** to save the schedule as a DXF file.

3. Generate the elevation and sections for a column:
a. Select **Reports > Elevation**.
The **Select Columns** dialog opens.
b. Select C1 and W1 in the columns list.

   **Tip:** You can modify the drawing and detailing options by clicking the **Detailing & Drawing Settings** button (also by selecting **Settings > Detailing & Drawing Settings** before using this tool). You can also customize rebar mark styles from this dialog.

c. Click **OK**.
The elevation for the selected column and wall opens. This drawing contains section cuts at each reinforcement arrangement.
d. Click the **Save** tool in the view window.

e. Type `Tutorial_Col_Elev.dxf` and click **Save** to save the schedule as a DXF file.

4. Generate a bill of quantities:

   **a.** Either:

   select the **Bill of Quantities** tool ✡

   or

   Select **Reports > Bill of Quantities**.

   The **Bill Of Quantities** dialog opens.
b. Select the **BOQ Summary** and **Reinforcement Type Wise** options.

c. Select **€ - Euro** from the **Currency** drop-down list.

d. Type 90 (€/m³) for Grade C20/25 concrete and 4 (€/kg) for Grade Fy420 steel. Type 8 (€/m²) for the Shuttering value.

e. Click **OK**.

   The **BOQ Summary** and **BOQ Detailed - Reinf Type Wise** tabs open.

f. Either:

   click the **Print** tool to print out a copy of this report or

   click the **Save** tool to save an HTML copy of this report

5. Generate bar bending schedule:

   a. Select **BBS > Generate BBS**.

   The **Generate BBS** dialog opens.

   b. Select **C1** and **W1** in the list of columns groups.

   c. Select the **Continuous** option in the **Rebar Numbering** group.

   d. Select both the **Drawing** and **Spreadsheet** options in the **Schedule Format** group.

   e. Click inside the file path field, type **Sample1_Col_BBS** in the **Save As** dialog that opens, and then click **Save**.

   f. Click **Generate**.

   The BBS opens containing a text schedule of the bar bending schedule. If you have Microsoft® Office Excel® installed (or another spreadsheet program cable of opening .xlsx format spreadsheet files), the spreadsheet of the bar bending schedule opens.

   g. Close your spreadsheet application.

   h. Click the **Save** tool in the view window.

   i. Type **Tutorial_Col_BBS.dxf** and click **Save** to save the schedule as a DXF file.
To generate column design calculations

1. Either:
   select the Design Summary tool
   
   or
   
   select Reports > Design Summary
   
   The Design Summary opens.

2. Either:
   select the Design Calculations tool
   
   or
   
   select Reports > Design Calculations
   
   The Select Columns dialog opens.

3. Select columns C1 and W1 in the columns list.
   For this tutorial you will only output the detailed design for one column and one wall. You can check the All
   Columns option to include the full design report. Or, if you only need the calculations for one level of a
   column or wall, you can expand that entry and select the level of interest.

4. Click OK.

5. Either:
   
   click the Print tool to print out a copy of this report
   
   or
   
   click the Save tool to save an HTML copy of this report

To save the project and exit

1. Either:
   
   select the Save tool (on the main program toolbar)
   
   or
   
   select File > Save
   
   The Save As dialog opens.

2. Type Sample1_Col_tutorial.rcdx in the filename and click Save.

   
   RCDC closes and you are returned to STAAD.Pro.

Tutorial STAAD Input File

The following input file for STAAD.Pro is included with the installation of the product. It is included here as well.

```
** FILE CREATED ON : (19-09-2018, 02:49:43 PM)
** FILE IS GENERATED USING PlanWin
** PlanWin FILE : C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\Sample Models\Building Planner\Typical Ground +3 Storey Building.plnx
UNIT METERS MTONS
JOINT COORDINATES
```

EX. Bride Deck Loading Example

This example demonstrates how to apply vehicle loads per BS 5400 Part 2 on two lanes of a two span, steel girder bridge using the Bridge Deck workflow.

EX. To open the model in Bridge Deck workflow

1. Create a new file in STAAD.Pro.
2. Open the file and copy/paste the input file data (on page 5036).
3. Run an analysis on the structure.
4. Select Bridge Deck in the Workflows panel.

   Note: If you do not have a license for this module, you will not be able to proceed.

The Bridge Deck ribbon tab opens.

EX. To define the bridge deck

1. (Optional) If the mouse pointer is not already displayed as the Plate Cursor, in the Analytical Modeling workflow on the Geometry ribbon tab, select the Plates Cursor tool in the Selection group.

2. Press <CTRL+A>.
   All plate elements are selected in the entire model.
3. In the Bridge Deck workflow on the Bridge Deck ribbon tab, select the Create Deck tool in the Deck group.

   The Save Deck as dialog opens.
4. Type Northbound for the Name.
5. Click OK.

EX. To generate the influence surface for the deck

1. On the Bridge Deck ribbon tab, select the Loading > Influence Surface Generator tool in the Loading group.
A temporary STAAD input file (filename_deck.std) is sent to the STAAD analysis engine for processing. The STAAD Analysis and Design dialog opens to display the progress. When the analysis is complete, the dialog closes automatically.

2. On the Bridge Deck ribbon tab, select the Loading > Influence Diagram tool in the Loading group. The Diagrams dialog Influence tab (on page 3136) opens.

3. Select the Diagram Type as Node Displacement.
   The Parameter field updates to display Node Displacement and the object field updates to Node.

4. Select the Node Displacement as Y (Global Y direction).

5. Select the Node as 104 (approximately center of the deck, mid-span of the longer span).

6. Click OK.
   The influence surface for the vertical displacement at node 104 is drawn on the deck.

EX. To define the roadway lanes

**Note:** The deck is selected in the Bridge Deck ribbon tab Deck group by default, since only one deck has been defined. Otherwise, it would be necessary to select the correct deck on which a new roadway is to be defined.

1. On the Bridge Deck ribbon tab, select the Define Roadway tool in the Deck group.

   The Roadways dialog (on page 3123) opens.

2. Click New.
   The Define Roadway dialog (on page 3125) opens.

3. Type 0.61 m for Curb A: Origin Z value and 6.35 m for Curb B: Origin Z value. Leave all other values as the default.
   The preview updates to display the roadway on the currently selected deck.

4. Click OK.
   Roadway CW 1 is now added to the Roadways list in the Roadways dialog and is outlined in blue on the deck in the active view window.

5. Click Close.

EX. To place automatically generated loads on the roadway

1. On the Bridge Deck ribbon tab, select the Loading > Run Load Generator tool in the Loading group.
   The Load Generator Parameters dialog (on page 3130) opens.

2. On the General tab, Select BS5400 Part 2 as the Design Code.
   The <code>tab updates to BS5400.

4. Select the BS5400 tab (on page 3132).
   **Note:** For this example, the default single load case with the nominal HB vehicle and unit of 30 are OK.

5. Select the Node Displacements tab.
**Note**: An action must be defined for which the maximum results determine the placement of the moving loads. This example will use the same action as reviewed above in the influence surface.

6. Enter the following data into the Node Displacements table:

<table>
<thead>
<tr>
<th>Node</th>
<th>Displacement</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>104</td>
<td>Y</td>
<td>+ve</td>
</tr>
<tr>
<td>104</td>
<td>Y</td>
<td>-ve</td>
</tr>
</tbody>
</table>

7. Click **OK**. The program analyzes the deck to obtain the critical load positions for the specified action.

A summary of the analysis is opened in your default text editor (e.g., Notepad). The file (named `filename_deckx.out`) is saved in the same location as the input file. Close the text editor once you have completed reviewing this file.

**EX. To review the generated loads graphically**

1. Select **2:N04: Disp Y -ve** in the current load case drop-down list, found in the View toolbar.
2. Either:
   - Select View > Structure Diagrams....
   - or
   - Right-click anywhere in the active view window and then select Structure Diagrams... from the pop-up menu.
   - The **Diagrams** dialog opens.
3. Select the **Deck tab** (on page 3137).
4. Select to display **Loads** and **Vehicles** in addition to Roadways (on by default).
5. Click **OK**.

The placement of the loads and vehicles are overlayed on the bridge deck. Note that the defined roadway was wide enough for two lanes of traffic, and these were created automatically.

**EX. To transfer the load case to the STAAD.Pro model**

To transfer the generated load cases to STAAD.Pro for analysis and design, do the following.

1. On the **Bridge Deck** ribbon tab, select the **Loading > Create Loading in STAAD Model** tool in the **Loading** group.
   - A message dialog opens to confirm the load was successfully added in the STAAD input file.
2. Select the **Analytical Modeling** workflow.
3. On the **Loading** page, review the loads added to the input file in the **Load & Definitions** dialog.

   **Note**: One load was added for each action requested in the **Load Generators Parameters** dialog.

4. (Optional) Select the **Design | Steel** page and define parameters for the BS5400 code to perform a member design in addition to analysis for the generated loads.
5. On the **Analysis and Design** ribbon tab, select the **Run Analysis** tool in the **Analysis** group.

EX. To create model used for pushover example

To quickly set up the model used for this example, use the following procedure.
Only one pushover definition can be added to a model. Therefore, this example will start with a model you can add the pushover definition to. The end result will be functionally equivalent to the example model installed with the program.

1. Start an empty STAAD.Pro model in the analytical modeling workflow.
   Refer to GS. To create a new STAAD.Pro model (on page 33) for additional details.
2. On the Utilities ribbon tab, select the Command File tool in the Edit group.

   The STAAD.Pro Editor window opens.

3. Click Copy to Clipboard below.

4. In the STAAD.Pro Editor window, select the Paste tool on the Home ribbon tab.
The model contents are pasted into the editor.

5. Save and close the STAAD.Pro Editor.

The model opens in the Analytical Workflow.

EX. To define general pushover data

1. On the Loading ribbon tab, select the Pushover tool in the Define Loading Systems group. The Create New Definitions / Load Cases / Load Items dialog opens with only the Pushover tab displayed.

2. On the Define Input tab, select the General Input Parameters option.

3. Select Moment Frame as the Type of Frame.

4. Select Ignore Effect from the Geometric Non-Linearity Effect drop-down list.

5. Set the Displacement Incremental Value option and then type 0.010 (in) in the text field.

6. Click Add.

7. Select the Member Specific Parameter option.

8. Set the Expected Yield Stress option and then type 36.0 (kip/in²) in the text field.

Note: You will assign this parameter to members in a later procedure.

9. Click Add.

In the next procedure, you will define the loading pattern and spectrum data, so you can leave the Define Pushover dialog open.

EX. To define loading pattern and spectrum data

1. On the Define Pushover dialog, select the Define Loading Pattern tab.

2. Type 250 in the Number of Push Load Steps.

3. Click Add.

4. Select the Define Spectrum Data tab.

5. Type 5.0 (%) in the 1st Spectrum text field.

6. Delete the values from the remaining spectrum fields.

7. Select Class A from the Site Category drop-down list.

8. Type 1.0 in both the At Short Period and At One - Second Period text fields.

9. Click Add.

In the next procedure, you will define the solution control, so you can leave the Define Pushover dialog open.

EX. To define the solution control

1. On the Define Pushover dialog, select the Define Solution Control tab.

2. Select the Push Upto Defined Displacement at Control Joint option.

3. Select X Axis for the Direction.

4. Type 5.00 (in) in the Joint Displacement Value text field.
5. Select 10 as the Joint Number.
   The drop-down list contains the node numbers within the entire model.
6. Click Add.
7. Click Close.

EX. To assign the member-specific parameters

1. On the Load & Definition dialog, expand the Definitions > Pushover Definitions section.
   You will see the input parameters for the pushover definition you have added.
2. Select the entry labeled FYE 36.00000.
3. In the Assignment Method group, select Assign To View.
4. Click Assign.
   You are prompted to confirm you want to assign to all visible members in the view.
5. Click Yes.

EX. To specify and run the pushover analysis

1. Either:
   select the Analysis page
   or
   on the Analysis and Design ribbon tab, select the Analysis Commands tool in the Analysis Data group

   The Analysis/Print Commands dialog opens.
2. Select the Perform Pushover Analysis tab.
3. Click Add.
4. Click Close.
5. On the Analysis and Design ribbon tab, select the Run Analysis tool in the Analysis group.

   The STAAD Analysis and Design dialog opens.
6. Select the Go to Post Processing Mode option.
7. Click Done.

   The Postprocessing Workflow opens.

EX. To review pushover displacement results

If you did not select the Postprocessing option in the results dialog in the previous procedure, select the Postprocessing workflow.
1. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
2. Select the **Graphs** tool in the **Pushover** group.
   The Capacity Curve graph and Capacity Curve table open.
   
   **Note:** The last load step (63) has a displacement that exceeds the maximum of 5.0 in specified in the pushover parameters.

3. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
4. Select the **Node Results** tool in the **Pushover** group.
   The Node Displacements and Support Reactions tables open.
   
   **Note:** These tables display the values for the entire structure for a selected load step. The deflected shape for the current load step is also displayed graphically.

5. Type 63 in the **Select Load Step** field and then press `<Enter>`.
   The tables and view window update.

6. On the **Results** ribbon tab, select the **Layouts** tool drop-down in the **Dynamics** group.
7. Select the **Beam Results** tool in the **Pushover** group.
   The Beam Hinge Results and Beam Force Detail tables open.

8. Repeat clicking the up arrow adjacent to either **Select Load Step** field until load step 4 is displayed.
   
   **Note:** The first hinge initially forms at this step. This is denoted with a green hinge, representing immediate occupancy status.

9. Repeat clicking the up arrow until about load step 44 is reached.
   Several more hinges have formed at the top of the elastic range and the first hinge has now turned blue, representing the Life Safety range of the acceptance criteria.
OpenSTAAD is a library of exposed functions allowing engineers access to STAAD.Pro's internal functions and routines as well as its graphical commands. With OpenSTAAD, you can use Visual Basic for Applications (VBA) macros to perform such tasks as automating repetitive modeling or post-processing tasks or embedding customized design routines. Following an open architecture paradigm, OpenSTAAD was built using ATL, COM, and COM+ standards as specified by Microsoft. This allows OpenSTAAD to be used in a macro application like Microsoft Excel or Autodesk AutoCAD. OpenSTAAD can also be used to link STAAD data to Web-based applications using ActiveX, HTML, and ASP.

OpenSTAAD allows engineers and other users to link in-house or third-party applications with STAAD.Pro. For example, a user might create a spreadsheet in Excel to analyze and design a circular base plate using support reactions from STAAD. With OpenSTAAD, a simple macro can be written in Excel or within the STAAD environment to retrieve the appropriate STAAD data and automatically link the results. If the STAAD file changes, so will the Excel sheet! With a built-in VBA editor, macros can be written inside STAAD using VBA to create new dialog boxes or menu items which run design codes or specific structural components (like certain connections) that automatically link to STAAD's familiar reporting tables. A cumbersome export/import link between two or three software is not required.

OS. Help and Documentation

OpenSTAAD Help Organization

The OpenSTAAD documentation is organized in the following manner:

- Getting Started
- Fundamentals
- Using Macros
- OpenSTAAD Application Objects
- Troubleshooting
- Examples
Printing Help and Documentation Files

Topics in the OpenSTAAD help system may be printed when they are opened in the Help Viewer application. To print a topic:

1. Select the topic you wish to print from the Table of Contents.
2. Click the Print tool.
   
   or
   
   Press <Ctrl+P>.

OS. Function List Organization

The list of functions is formatted in the following way:

- The name of each function appears in large, bold typeface at the top of the page.
- A general description follows which contains the purpose of the function, and provides general comments, constraints, and recommendations for using it.
- The Visual Basic (VB) syntax for the function appears next in bold typeface. All function syntax definitions consist of the function name and then the comma separated parameters, e.g.,
  functionname param1, param2, ... , paramn
  
The function and all its parameters are usually written on a single line, but for long lines of code, a line continuation character may be used to make the code easier to read. In VB, the line continuation character is a space followed by an underscore ( _ ).
- Following the function syntax definition is a description of each parameter required by the function. Note that the names of the parameters are just example names. If the parameter is a variable name for storing results returned by the function, or if you are passing a parameter required by the function as a variable, you can give it any legal variable name.
- If the function directly returns a value (often a boolean value indicating if the function was successful or not), a section on interpreting the return value is included.
- Then an example of the function is provided. In some cases, the example is just a short code snippet; in other cases a fully viable macro or program is given. All code provided will be able to work within the STAAD macro editor or an external VBA editor (e.g., Microsoft® Office Excel®).
- Finally, a list of related functions are listed, where applicable.

OS. Fundamentals of OpenSTAAD

OS. Programming Languages

OpenSTAAD supports Visual Basic for Applications (VBA), which is an implementation of Microsoft's Visual Basic language and an associated IDE.

Although OpenSTAAD supports all major programming languages used today capable of calling COM components, it is impractical to document the usage of each and every function in all of these languages. Most of the example programs or code snippets for each documented OpenSTAAD function are written in VBA.
for Excel or AutoCAD VBA. The reason is that with OpenSTAAD 2.0 and higher, STAAD.Pro is equipped with a functional VBA editor capable of writing macros only in VBA.

Documentation for VBA is beyond the scope of this manual and Bentley does not provide direct support on how to write VBA macros. There are, however, several useful and free sites on the Web to assist a beginner on writing macros in STAAD, Excel, AutoCAD, or any other VBA compliant software. It should be noted that the VBA language is the same from software to software. However, the functions, objects, and core libraries will obviously vary.

The sites recommended by Bentley are as follows:

- [https://stackoverflow.com](https://stackoverflow.com)
- [https://www.oreilly.com/](https://www.oreilly.com/)
- [http://www.wrox.com](http://www.wrox.com)

Also, it is worth noting that many programs such as MicroStation and Microsoft Office Excel have a useful Record Macro feature. You can run the recorder and then select any commands from the program’s ribbon tabs. The corresponding VBA syntax will automatically be generated.

For additional information on using macros and VBA in Excel or other Microsoft Office programs, Microsoft’s MSDN is a recommended starting point:

**OS. OpenSTAAD User Forum and Code Resource**

Bentley hosts an OpenSTAAD community on the company's Bentley Communities website. Here you can exchange macros with peers using the file upload, ask questions in the community forum, or share other information in the community blog and image gallery.

Bentley hosts an OpenSTAAD community on the company's Bentley Communities website. Here you can exchange macros with peers using the file upload, ask questions in the community forum, or share other information in the community blog and image gallery.

Join the Bentley OpenSTAAD group at Bentley Communities today.

**Caution:** Code or files uploaded to Bentley Communities are not subject to a screening process in advance. Any files or code which are found to result in malicious behavior will be removed. Bentley Systems accepts no responsibility for any mistake, error or misrepresentation in or as a result of the usage of software code obtained from the Bentley Communities site.

**OS. Application Program Interface (API)**

The OpenSTAAD library of functions is classified under the following general categories:

- STAAD File Input and Output (I/O)
- Structure Geometry
- Member Specifications
- Properties
- Loads
- Output Results
OS. Instantiating the OpenSTAAD Library for Use

The first thing necessary to access STAAD project data from within another application is to instantiate, or create an instance of OpenSTAAD within the other application. In Visual Basic for Applications (VBA), this may be done by creating an object variable and then assigning to it the OpenSTAAD object. The VBA `GetObject` function may be used for this.

The object which controls the STAAD.Pro environment is referred to as `StaadPro.OpenSTAAD`. This object must be created in order to get access to any of the internal graphical functions within STAAD.Pro (including the creating of menu items and dialog boxes) as well as access to STAAD's viewing, geometry modeling, results grid, and post-processing functions. The following VBA function can be used to instantiate or create this object:

```vba
Set MyObject = GetObject("filepath", "objectclass")
```

Where:
- **MyObject** the Object name declared in a previous `Dim` statement.
- **filepath** the optional string providing the full file path and name of the file containing objects to retrieve.
  In the case of OpenSTAAD, this can be omitted, along with the trailing comma.
- **objectclass** the string representing the class of the object. In the case of OpenSTAAD, this is always `Staadpro.OpenSTAAD`.

Thus:
```vba
Set objName = GetObject("StaadPro.OpenSTAAD")
```

At the conclusion of your OpenSTAAD application, the OpenSTAAD object(s) should be terminated, to unlock the handles within the application to the OpenSTAAD functions, and to free system resources.

**Example**

```vba
Sub How2Begin()
    'Create a variable to hold your OpenSTAAD object(s).
    Dim objOpenSTAAD As Object
    'Launch OpenSTAAD Object
    Set objOpenSTAAD = GetObject(, "StaadPro.OpenSTAAD")
    'At the end of your application, remember to terminate the OpenSTAAD objects.
```

Set objOpenSTAAD = Nothing
End Sub

OS. Function Return Value

Most OpenSTAAD functions return a value to either:

- indicate the success or failure of the function (a Boolean result), or
- results value of the function (a numeric value result).

If a function returns a Boolean result and that return value for an OpenSTAAD function is equal to 0 (zero), it means that OpenSTAAD was unable to execute the function. If you see this result, check that you have passed all the required parameters to the function. Make sure that all parameters being passed are valid. A return value of 1 (one) indicates that OpenSTAAD successfully executed the function. Unless specified otherwise, results returned by a function are stored in variable names passed to it for the purpose.

A few of the OpenSTAAD Application functions return the results as the return value of the function. In those cases, the above comments regarding the function return value do not apply.

If a function returns the value of the function,

```vbnet
Dim returnValue
returnValue = objOpenSTAAD.BooleanReturn (param1, param2, … ,paramn)
```

Tip: See “Functions and Subroutines” (on page 5050) for information on parenthesis required in VB Syntax.

OS. STAAD Nomenclature

In STAAD documentation and in the program menus and dialog boxes, the terms “member” and “beam” are used interchangeably. Use of the term "beam" should not be taken to imply that the member cannot take an axial load. Similarly, the terms "joint" and "node" are used interchangeably in STAAD. Both terms refer to the connections between elements.

Connections are also referred to as incidences. The terms “member incidences,” “plate incidences,” and “solid incidences” refer to the nodes that connect these elements to other elements and supports.
OS. OpenSTAAD Compatibility with STAAD.Pro

For optimum performance, OpenSTAAD should be run in STAAD.Pro 2002 or higher. The object which controls the STAAD.Pro graphical interface (StaadPro.OpenSTAAD - dialogs, modeling tools, etc.) is only available in STAAD.Pro 2003 or higher.

As software development proceeds, it is sometimes necessary to modify STAAD's database to accommodate new features or to maximize efficiency and increase processing speed. STAAD.Pro 2002 is the first STAAD release to include OpenSTAAD. All subsequent releases of OpenSTAAD will be backward-compatible with STAAD.Pro 2002.

It may be possible to run at least some of OpenSTAAD's functions in earlier releases of STAAD.Pro or STAAD-III, but the results may be unpredictable, since OpenSTAAD did not exist at that time, and therefore compatibility with OpenSTAAD was not considered during the development of these earlier STAAD versions. Bentley Systems, Inc. does not provide any technical support for OpenSTAAD running in STAAD versions prior to STAAD.Pro 2002.

In terms of STAAD's input file, STAAD.Pro is backward-compatible with all previous STAAD releases. To use OpenSTAAD on a project that was created using an earlier version of STAAD.Pro or STAAD-III, you can open your old input file in STAAD.Pro 2002 and run the analysis. This action will create a new database in a format fully compatible with OpenSTAAD.

OpenSTAAD is compatible with any version of Microsoft® Office Excel® that supports VBA macros. OpenSTAAD is also compatible with Autodesk AutoCAD® 2000 (or higher) VBA.

With OpenSTAAD 2.0 and higher (available with STAAD.Pro 2003 and higher), a VBA editor is embedded within the STAAD.Pro environment. The version of VBA which the editor supports is not 100% VBA compatible. There are a few functions which can be supported in the Microsoft version of VBA which are not supported in the VBA editor/compiler which comes with STAAD.Pro. Every attempt is being made to support these functions. Currently, the functions which are not supported are not yet documented in this manual.

OS. Visual Basic Conventions

Comments

In Visual Basic or Visual Basic for Applications, an apostrophe (’) is used to denote a comment. Anything to the right of the apostrophe will be ignored by the program.

Tip: Throughout this documentation, these are displayed in the color green to make comments visually distinct from the remaining code.

Declaring Arrays

VB/VBA is flexible in the way it allows arrays to be declared. Most examples involving arrays in this reference manual will conform to the C++ zero indexing convention. In an array of 6 values, the positions in the array are referred to as 0-5. Therefore an array of 6 values would be declared as follows:

Dim pdArray(5) As Double

or

Dim pdArray(0 To 5) As Double
In VB, a six value array can also be declared as:

```vbnet
Dim pdArray(1 To 6) As Double
```

In doing so, however, we might find that our loops and other statements used to access the various positions in the array might not work correctly in C++.

**Line Continuation Character**

A long coding statement can be written on more than one line, to make the code easier to read. The VB line continuation character consists of a space followed by an underscore at the end of the line. The line of code beneath the continuation character will be handled as though it was written on the same line as the line continuation character.

**Functions and Subroutines**

Though functions and subroutines perform similar actions in any language, it is important to understand a key difference in order to make writing OpenSTAAD macros easier. A function can return a value back to the function or routine that called it. A subroutine, on the other hand, does not directly return a value. Instead, a subroutine must make use of the ByRef methodology internally. OpenSTAAD has been written so that you can use many of its functions to return more than one value via a single function. While this is a very powerful feature, it can lead to some confusion given how VB syntax uses parenthesis. In VB syntax, a subroutine does not use parenthesis to enclose any values which are passed to it. VB reserves their use for functions only.

Thus, in OpenSTAAD the subroutines which are used to return multiple values from the model input, analysis results, or design results are required to use the subroutine syntax.

**Note:** As this is a merely a result of VB syntax and not that these OpenSTAAD functions behave differently, the documentation simply refers them all as "functions."

**Tip:** Often, though, the data passed in such a function is in the form of an array, which do use parenthesis (without a space) to indicate their dimensions.

```
Example

objOpenSTAAD.GetNodeDisplacements nNodeNo, nLC, pdDisps(0)
' The line of code above may also be written as the line shown below:

objOpenSTAAD.GetNodeDisplacements _
nNodeNo, nLC, pdDisps(0)
```

**OS. Using Macros in STAAD.Pro**

This section describes how to use the STAAD.Pro Script Editor to create a new macro or load existing macros in STAAD.Pro. It also describes how to run the macros you have created in the STAAD.Pro Script Editor by adding a simple menu item.

**OS. To start a new macro project**

To create a new macro project and open it in the STAAD.Pro Script Editor, use the following procedure.
1. On the **Utilities** ribbon tab, select the **Macro** tool in the **Developer** group.

   - The **Macro** dialog opens.

2. Click **Create New**.
   - The **New Macro File Name** dialog opens.

3. Type a **File name** and optional **Description of Macro**.
   - For this tutorial, type **Frame** in the **File name** field and then type **Create a 2D frame with supports** in the **Description of Macro** field.

4. Click **New**.
   - The STAAD.Pro Script Editor window opens. An empty script is loaded with for your file.

OS. To import an existing macro

1. On the **Utilities** ribbon tab, select the **Macro** tool in the **Developer** group.

   - The **Macro** dialog opens.

2. Click **Import**.
   - The **Add an Existing Macro** dialog opens. The controls in this dialog are analogous to those in the **Select New Macro File Name** dialog, though some are inactive.

3. Navigate to and select the existing macro file.

4. Click **Open**.

   - The macro name is added to the list of names in the Macro dialog.

**Related Links**

- **EX. OpenSTAAD Example Files** (on page 4311)

OS. To run a linked macro

1. On the **Utilities** ribbon tab, select the **User Tools** tool in the **User Tools** group.

   - A drop-down menu displays all of the linked macros.

2. Select the macro you want to run from this list.

OS. Displaying OpenSTAAD Functions in the Objects Browser

The objects browser is very useful to see an overview of functions while writing OpenSTAAD macros.
1. Open the SAX Basic editor.

   **Tip:** Start a new macro or edit an existing one.

2. Right click anywhere in the window and select **Edit > References** from the pop-up menu.

   The **References** dialog opens.

   ![References Dialog](image)

   3. Check the option for **OpenSTAADUI (1.0)** in the Available References list and click **OK**.

   Now, when the **Browse Object** tool is selected, you will see OpenSTAAD functions included in the Library list.
OS. STAAD.Pro Script Editor window

This application is used to write macros for use with STAAD.Pro. It is a small yet powerful programming application with tools for helping you create and debug macros.

Tip: The STAAD.Pro Script Editor is built on the WinWrap® Basic Editor platform. Select the Help tool in the top-right corner of the application to get help on both the WinWrap application as well as the WinWrap Basic language, which supports Visual Basic .NET™.

</tbody>
</table>

**OS. UserDialog Editor**

Used to create end-user dialogs for your macro. This will generate the `Begin Dialog…End Dialog` block in the macro code.

The editing tools are located along the top toolbar.

The user interface items are on tool pallet on the left side. Click any tool to active that item for layout. Then click in the dialog view to place that tool.

**OS. References dialog**

Used to include references for APIs, including OpenSTAAD.

**OS. OpenSTAAD API Documentation**

Programmer reference documentation for the OpenSTAAD API is installed separately at C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\Help\OSAPP\index.html (typical location).

1. Select the **File** ribbon tab.  
   The backstage view opens.

2. Select **Help > OpenSTAAD Help**.  
   The OpenSTAAD Documentation opens in your default web browser.

**OS. Troubleshooting**

The following is a list of error messages or warnings which may be displayed and methods used to address them.

**OS. Method Object Failed**

Error message:
Method 'OpenSTAADFuntionName' of object IOutput failed.

where OpenSTAADFuntionName is the name of an OpenSTAAD function. For example:
Method 'GetMemberBetaAngle' of object IOutput failed.

**Solution**

Check to be sure that you are passing all parameters required by the function. If a parameter is missing, or if the parameter being passed is not valid, the Method ...of object IOutput failed message may appear. For example, the message may appear if a member number is passed to the function, but that member number does not exist in the currently open STAAD file.

You may also receive similar messages if your version of STAAD.Pro is not compatible with OpenSTAAD. OpenSTAAD is compatible with STAAD.Pro 2001 Build 1006.US.REL and higher. You will need to reanalyze your model in that build. This is because we switched the way the data is recorded in Build 1006 to save more space. Build 1006 US.REL was released in November 2001.

**Note:** UK Builds prior to STAAD.Pro 2002 are not compatible with OpenSTAAD.

**OS. Function is not retrieving correct values**

Check to be sure that you have saved the STAAD file after making changes to the input before you run any OpenSTAAD functions that retrieve input information. If you are running STAAD functions that retrieve analysis results, check to be sure that you have saved the STAAD file and re-run the analysis after making any changes to the input.

**OS. Type Mismatch**

Error message:
Type mismatch

Check to make sure that you have declared all variables using the DIM statement at the beginning of your program or macro, e.g.:

```
Dim pnIsReleased As Integer
Dim pdSpringStiffnesses(0 To 5) As Double
Dim pdPartialMomRelFactors(0 To 2) As Double
```

Confirm that when you pass array variables to the function, you have specified the starting position in the array for the function to use in filling up the array. For example:

```
objOpenSTAAD.GetFullMemberReleaseInfoAtStar 3, pnIsReleased, _
pdSpringStiffnesses(0), pdPartialMomRelFactors(0)
```

**OS. Property or Method Not Supported**

Error message:
Object doesn't support this property or method

Check to make sure you have typed the function name correctly.
OS. ActiveX Component in Microsoft® Excel

Error message:
ActiveX component can't create object
when attempting to run an OpenSTAAD macro in Microsoft Excel.

Are macros enabled?
When you open the Excel file, is it asking you to Enable Macros?
If so, make sure you click Yes. If not, you need to change the security settings in Excel. Select Tools > Macro > Security... from the Excel menu. Make sure the Security Level is set to Medium. Close Excel down (completely, not just the file) and reopen the file again. This time it should ask you if you want your Macros enabled or disabled. Choose Enabled.

OpenSTAAD DLL not registered
When you run your macro, if it still gives you the error ("ActiveX component can’t create object"), it might be because the OpenSTAAD library was not registered properly when the program was installed.

Register the DLL
1. In Windows Explorer, go to the following location:
   \C:\Program Files\Bentley\Engineering\STAAD.Pro CONNECT Edition\STAAD\Plugins\Struclink\.
   
   Note: The path to the file OpenStaad.Registration.exe may be different on your computer if you did not use the default installation path provided by the STAAD.Pro installer when you installed your software – if so, go to folder corresponding to the actual location on your computer.

   3. Right-click on the file OpenStaad.Registration.exe and select Run as Administrator from the pop-up menu.
   4. Click Register OpenSTAADUI to register the DLL.
   A message dialog opens indicating that the OpenSTAADUI type library is registered. If the registration did not succeed, please contact our technical support staff for further instructions.
   5. Click OK.

   6. Try opening and running the Microsoft Excel beam example file provided with your STAAD.Pro software (C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\OpenSTAAD\Rectangle-beam.xls).
   7. Close all the STAAD.Pro instances and open only the relevant STAAD.Pro model.
   8. Run the macro.

OS. User Type Not Defined

The message may be appearing because the OpenSTAAD library references have not been included. The VBA compiler therefore does not know which functions are associated with the OpenSTAAD object.

There are two ways to eliminate this error message:
1. Declare the OpenSTAAD object *As Object*, instead of *As Output*, e.g.
   
   ```vba
   Dim objOpenSTAAD As Object
   ```

2. Include the OpenSTAAD library reference in your VBA editor. This second option has the added benefit that whenever you do it, the compiler will now recognize the OpenSTAAD object and will pop up a list of functions whenever you refer to the object in your VBA editor.

   To include the OpenSTAAD library reference, select *Tools > References* in your VBA editor. A dialog titled *References – Normal* opens. You will see a scroll box inside the dialog box labeled *Available References*. Scroll down through the list of references until you find and entry labeled *OpenSTAAD 1.0 Type Library*. Toggle on the corresponding check box, then click *OK*.

   Now re-run your macro to see if the problem with the *User Defined type not defined* error message has been solved.

**OS. Files Not Compatible**

**Error message:**

One or more results files are not compatible with the current model and cannot be loaded...

You need to have a successful analysis before you can run any OpenSTAAD macro, including such simple macros as one that only asks for the number of nodes in the model. The program is not smart enough to know which commands will work and which will not when no results are present. It first checks to see if valid results are available. If they are not, it displays the error message and terminates.

You can use the OpenSTAAD command *AreResultsAvailable* in your macro to check to see if results are available. In some cases, this function also will result in the error message *One or more results files are not compatible with the current model and cannot be loaded*.... That means that even though the STAAD results file with an ANL extension has been created, the file contains only error messages and no meaningful results.

You can also try inserting a *FINISH* command in your input file preceding the location in the input that is causing the analysis errors. Depending on whether the errors take place before any analysis is performed, you might get rid of the original error message, but in its place you may see the message, *No Results Available*. However, the best way to eliminate this problem is to modify your input file so that you obtain a successful analysis before you try to run your OpenSTAAD macro.

Under certain conditions, you might get this *...results files are not compatible...* error message, even though the analysis runs successfully. OpenSTAAD currently will not work with the Moving Load Generator. The reason is that the results from the Moving Load Generator are not kept in the same database as the other STAAD results. Therefore, when OpenSTAAD tries to read the Output File, it is not able to find those missing load results, so it displays an error message and stops processing the macro. This same situation is in effect for any other loads that you are unable to see until you perform the analysis, like UBC loads, for example. If the loads are defined in the input file, OpenSTAAD will work fine, but not with loads that are only generated when the analysis is run, because these results are not kept in a location where OpenSTAAD can find them.

If you remove your moving load generation command from your input file, and run the analysis, you should then be able to run your OpenSTAAD macro.

**OS. Macro Tutorial**

This tutorial will take you step-by-step through the process of creating a practical macro used to generate a parametric 2D frame with supports.
The assumptions behind this parametric frame are:

- 2D frame lies in the XY plane at Z = 0 (with first support node at the origin)
- All bays are of equal width and height
- The user specifies the units of length before running the macro
- All supports have the same type and all nodes at Y = 0 are supports

Most of these assumptions could be either validated for altered with some changes or additions to the macro presented in this tutorial.

OS. To start a new macro project

To create a new macro project for this tutorial and to then open it in the STAAD.Pro Script Editor, use the following procedure.

The macro used in this tutorial is intended to run in an empty file. Therefore, you should start with an new STAAD input file in the Analytical Modeling workflow.

1. On the Utilities ribbon tab, select the Macro tool in the Developer group.
The Macro dialog opens.

2. Click Create New.
   The New Macro File Name dialog opens.

3. Type a File name and optional Description of Macro.
   For this tutorial, type Frame in the File name field and then type Create a 2D frame with supports in the Description of Macro field.

4. Click New.
   The STAAD.Pro Script Editor window opens. An empty script is loaded with for your file.

5. Select the line ‘TODO: Add your code here (i.e., line 4) and press <Delete>.

OS. Creating the User Dialog

The form is the dialog which a user will use to specify the frame parameters. This form will used text entry fields for the frame size and then a pair of options to allow the user to select the support type.

OS. To create the dialog form

Your cursor should be located where the dialog code will be inserted. If you deleted the comment line in the previous procedure, then your cursor is in the correct location (i.e., line 4).

1. Select the User Dialog tool in the Design group.

The UserDialog Editor opens.

2. Either:
   Click the Edit Item Properties tool
   or
   Right-click anywhere in the form layout
   The Edit User Dialog Properties dialog opens.

3. Type 600 in the Width field and then 200 in the Height field.
   These values are somewhat arbitrary, but allow for a sufficient amount of space to include the dialog controls.

4. Type 2D Frame Model in the Caption field.
5. Click Close.

6. Select the Set Grid tool.

   The Grid Settings dialog opens.

   7. Type 5 for both the Horizontal and Vertical grid values.

8. Click OK.
OS. To create the text fields and labels

1. Select the **Add Text** tool.
2. Click somewhere near the top, left corner of the form.

3. Repeat steps 2 and 3 to add four additional text labels along the left side of the dialog. This does not have to be precise. The labels and fields will be aligned by coordinates in a later step.

4. Select the **Add TextBox** tool.
5. Click a point to the right of the first label to add a data field in the form.
6. Repeat steps 4 and 5 to add three additional text boxes.
7. Edit the location and caption for the first label:
   a. Right-click on the first label.
      The **Edit Text Properties** dialog opens.

      ![Edit Text Properties dialog]

   b. Type the following values to define the label layout:
      - Left = 20
      - Top = 20
      - Width = 190
      - Height = 15 (default if you placed with a click)
   c. Type No. of Horizontal Bays: in the **Caption** field.
      Leave the remaining fields as their defaults.
   d. Click >>.
The properties for the next control added are displayed. This allows you to quickly make changes to the controls without the need to close and reopen this dialog.

8. Repeat step 7 to update the layout and caption for the remaining text labels as indicated below.

<table>
<thead>
<tr>
<th>Label Name</th>
<th>Rectangle (Left, Top, Width, Height)</th>
<th>Label Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text2</td>
<td>20,45,190,15</td>
<td>No. of Vertical Bays:</td>
</tr>
<tr>
<td>Text3</td>
<td>20,70,190,15</td>
<td>Vertical Distance:</td>
</tr>
<tr>
<td>Text4</td>
<td>20,95,190,15</td>
<td>Horizontal Distance:</td>
</tr>
<tr>
<td>Text5</td>
<td>20,130,190,15</td>
<td>Support Type:</td>
</tr>
</tbody>
</table>

When you click >> on Text5, the Edit TextBox Properties dialog opens for the first text box control.

9. Edit the location and name for the text box:
   a. Type the following values to define the text box:
      
      Left = 220
      Top = 20
      Width = 130
      Height = 15
   b. Type clmn in the Field field.
      This is the object name which the macro will use for this text box.
   c. Click >>.
      The properties for the next control added are displayed.

10. Repeat step 9 to update the layout and field name for the remaining text boxes as indicated below.

<table>
<thead>
<tr>
<th>Text Box Name</th>
<th>Rectangle (Left, Top, Width, Height)</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>TextBox2</td>
<td>220,40,130,15</td>
<td>row</td>
</tr>
</tbody>
</table>
11. Click Close.

OS. To create support options

Since the macro in this tutorial limits the support options to only fixed or pinned, using a pair of radio buttons to allow the user to select the support type is a good design choice. However, in a situation where three or more options were available, a drop-down list control might be a better choice.

1. Select the Add OptionButton tool.
2. Click a point to the right of the Support Type label (i.e., text5).
   The option control is placed.
3. Repeat steps 1 and 2 to add a second option to the right of the first.
4. Right-click on the first option control.
   The Edit OptionButton Properties dialog opens.
5. Type the following values to define the location:

   Left = 220
   Top = 130
   Width = 90
   Height = 15

6. Type Fixed in the Caption field.
7. Type sprt in the OptionGroup combo box.
8. Click >>.
   The properties for the second option control are displayed.
9. Repeat steps 5 through 7 except type 370 in the Left field and Pinned in the Caption field.

   Tip: Since the option group was previously defined, you can now selected from the drop-down list in the combo box rather than re-type its name.

10. Click Close.
    The Edit OptionButton Properties dialog closes.
To add the dialog buttons

The last step in defining the dialog is to add the OK and Cancel buttons.

1. Click the **Add OK Button** tool.
2. Click a point near the bottom, right corner of the form. The OK button is placed.
3. Click the **Add Cancel Button** tool.
4. Click a point to the right of the OK button.

*Note:* This is the recommended button order according to Microsoft's design guidelines.

The Cancel button is placed.

5. (Optional) Either:
   - right-click on either button to precisely edit the location
   - drag the buttons to align them to the grid

6. Select the **Save and Exit** tool.
   - The **UserDialog Editor** closes.

The dialog definition code is added to your macro:

```
Begin Dialog UserDialog 600,200,"2D Frame Model" %GRID:5,5,1,1
Text 20,20,190,15,"No. of Horizontal Bays:",.Text1
Text 20,45,190,15,"No. of Vertical Bays",.Text2
```

**OS. Macro Tutorial**
Tip: Now is a good time to save the work done to this point.

OS. To dimension the variables and add initial values in the dialog

You must dimension all the values you will use in the program. Further, it's a good idea to populate the dialog with initial values for the user.

1. Select the automatically generated line of code `Dialog  dlg` (i.e., line 23) and delete the line contents.
2. With your cursor after the line of code `Dim  dlg  as  UserDialog`, type the following to dimension the variables in use:

   ```vba
   Dim dlgResult As Integer
   Dim crdx As Double
   Dim crdy As Double
   Dim crdz As Double
   Dim n1 As Long
   Dim n2 As Long
   Dim ii As Long
   Dim s1 As Long
   ```

   **Note:** As you begin to type, the IntelliSense will provide options for the variable types. You can make use of the IntelliSense to help quickly complete lines and reduce typos in your source code.

3. Type a single quote mark followed by `Initialization`. 
The single quote mark is used to denote a comment. It is best practice to add clear comments to document your source code.

4. Type the following values to populate the dialog input fields:

   `dlg.clmn = "3"
   dlg.row = "5"
   dlg.ht = "3"
   dlg.wdth = "5"

5. Type the following commands to open the dialog upon starting the macro.

   You'll also add a comment and a debugging command which is helpful for resolving any issues with your macro.

   `DlgResult = Dialog(dlg)
   Debug.Clear`

6. Type the following command to capture the result of the user action in the dialog:

   `If dlgResult = -1 Then 'OK button pressed
   Debug.Print "OK button pressed"
   ElseIf dlgResult = 0 Then 'Cancel button pressed
   Debug.Print "Cancel button pressed"
   End If`

   **Note:** The single quote mark after the world Then also indicates a comment. Comments like this can follow the programming instruction on the same line.

   The EndIf statement is automatically added by the editor to close the If statement if you press <Enter>.

You have now created the general set of instructions to the program what to do with the user action in the form.

You can test the macro now to see the dialog populated with the initialized values. Select the Run tool in the Execute group. The macro dialog opens. Click either OK or Cancel to close it. Neither perform any action at this point other than to log a debug message.

The next step is to have the script then perform the desired actions when the users clicks OK.

**Tip:** Now is a good time to save the work done to this point.

**OS. To get the user values**

1. Place your cursor just after the Debug.Print "OK button pressed" line and then press <Enter> several times to create additional space between this and the following line beginning with ElseIf.

2. Type the following commands to populate the variables with the values the user types into the dialog:

   `'Get the values
   clmn = Abs( CDb1(dlg.clmn) )
   row = Abs( CDb1(dlg.row) )
   ht = Abs( CDb1(dlg.ht) )
   wdth = Abs( CDb1(dlg.wdth) )
   sprt = CStr(dlg.sprt)`
Note: The last captures the support array position as a string whereas the others all capture absolute value of
the user input for the respective data fields.

3. Type the following debug statements to provide back the captured values:

   Debug.Print "No. of Horizontal Bays = ";clmn
   Debug.Print "No. of Vertical Bays = ";row
   Debug.Print "Vertical Distance = ";ht
   Debug.Print "Horizontal Distance = ";wdth
   Debug.Print "Support Type = ";sprt

4. Type the following command to set the initial values for the coordinate variables:

   crdx = 0
   crdy = 0
   crdz = 0

OS. To initialize OpenSTAAD and calculate the node coordinates

1. Type the following command to initialize OpenSTAAD:

   Set staad = GetObject(,"staadpro.openstaad")

   This command opens the connection to STAAD.Pro and the model currently open in the program.

   Note: You can initialize OpenSTAAD to any variable. Here, staad is used.

2. Type the following two For loops to calculate the nodal coordinates for each node in the frame.

   Note: There are two nested loops used because this is a 2D frame. The Z coordinate was previously set to
   zero and will not change.

   'Nodes
   For j = 2 To (row + 2)
       For i = 1 To (clmn + 1)
           crdx = (i - 1) * wdth
           staad.Geometry.AddNode crdx, crdy, crdz
       Next
       crdy = (j - 1) * ht
   Next

   Note: The Next command to close the For loop is added automatically once you press <Enter> after typing
   the For command line.

3. Type the following If ElseIf statement to get the desired support type.

   The support is created and the returned support reference number is stored to the variable s1.

   A “fall back” possibility is also added in case neither of the intended support types is somehow specified, then
   an error message is presented to the user.

   'Supports
   If sprt = "0" Then
       s1 = staad.Support.CreateSupportFixed()
   ElseIf sprt = "1" Then
       s1 = staad.Support.CreateSupportPinned()
   Else
       MsgBox("Select Proper Support Type",vbOkOnly,"Error")
       Exit Sub
   End If
**Note:** The OpenSTAAD command `staad.Support.CreateSupportFixed` can also be used to simply create a new support without using the return value. But by adding the parenthesis at the end, the script can take the returned support reference number which allows you to store that in the variable.

4. Type the following line to add a debugging statement for the returned support reference number:

   ```vbscript
   Debug.Print "Support return value = "; s1
   ```

5. Type the following type to assign the support types to the bottom nodes in the frame:

   ```vbscript
   For i1 = 1 To (clmn + 1)
   staad.Support.AssignSupportToNode i1, s1
   Next
   ```

**Tip:** Now is a good time to save the work done to this point.

**OS. To generate the frame members**

1. Type the following commands to add the columns:

   ```vbscript
   'Columns
   n1 = 1
   n2 = (n1 + clmn + 1)
   For k = 1 To (clmn + 1)*row
       staad.Geometry.AddBeam n1, n2
       n1 = n1 + 1
       n2 = n2 + 1
   Next
   ```

2. Type the following commands to add the beams:

   ```vbscript
   'Beams
   n1 = 1
   For k1 = 1 To row
       n1 = k1 * (clmn + 1)+1
       n2 = n1 + 1
       For k2 = 1 To clmn
           staad.Geometry.AddBeam n1, n2
           n1 = n1 + 1
           n2 = n2 + 1
       Next
   Next
   ```

3. Save your macro by either:

   - click the **File** ribbon tab and then select the **Save** tool in the backstage view
   - or
   - click the **Save** tool in the quick access toolbar
   - or
   - press `<Ctrl+S>`

Your frame macro is now complete. You are ready to test the macro to check your code.
OS. To test your macro

You can add break points through your code to assist in debugging. Practice adding one so you can read the debug print output you added.

If the program contains errors, the line where the program stops will be marked in red. Stop the program and then review your input to debug.

1. Click in the dark gray margin of the code editor just to the left of line number 57 (or the line containing cdrx = 0).
   A red dot appears to indicate this is a break point. The code will pause the execution at this point when executed.
2. Click the Run tool in the Execute group.

   The user dialog opens for input.
3. Change one or more values from their defaults.
4. Click OK.
   The code runs to the break point, which is now highlighted in yellow. The Immediate tab now shows the debug print statements. These should reflect any changed input you provided.

5. Click the Run tool in the Execute group again to continue to the next break point or to the end of the code.
6. Save your changes.
7. Select the File ribbon tab and then select Exit in the backstage view.

Your new macro is shown in the Macro dialog list.

**Note:** Testing the macro still runs within STAAD.Pro through OpenSTAAD, so you will have a frame generated if you tested it. You will need to start with a new, empty file to run the macro correctly.
OS. To add the macro to the list of user tools

Once you have completed testing of your macro, you can add it to the list of User Tools in the STAAD.Pro application. This allows you to run it with one click.

1. On the Utilities ribbon tab, select the Configure tool in the User Tools group.

   The Customize User Defined Tools dialog opens.

2. Click New.

3. Type 2D Frame Model in the name of the command.

4. Click [...] next to the Command field.

5. Navigate to and select your Frame.vbs macro file.

6. Click Open.

7. Click OK.

   Note: There are no parameters of external files used by this macro, so those fields are left empty.

• AD.2006.6.12 User Tools (on page 336)

OS. To run the Frame macro

1. Create a new analytical modeling input file.

2. (Optional) Change the units of length to a convenient value.

3. On the Utilities ribbon tab, select the User Tools > 2D Frame Model tool in the User Tools group.

   The 2D Frame Model dialog opens.

4. Type the number of bays in the horizontal and vertical directions.

5. Type the spacing of the bays in the horizontal and vertical directions (X and Y, respectively).

6. Select the Support Type.

7. Click OK.

   The frame with supports is generated.

OS. Frame.vbs Macro

This is the full contents of the Frame.vbs file. You can copy this by clicking Copy to Clipboard below and paste into the STAAD.Pro Macro Editor window.

    n2 = n2 + 1
Next

'Beams
n1 = 1
For k1 = 1 To row
    n1 = k1 * (clmn + 1)+1
    n2 = n1 + 1
    For k2 = 1 To clmn
        staad.Geometry.AddBeam n1, n2
        n1 = n1 + 1
        n2 = n2 + 1
    Next
Next

ElseIf dlgResult = 0 Then 'Cancel button pressed
    Debug.Print "Cancel button pressed"
End If
Alternate Control

If a user is asked to choose among three or more options, often a drop-down list is a better choice of control for the user interface. The macro can altered slightly to use a drop-down list. The list is populated by an array of strings which must be declared and populated before the dialog definition.

Sub Main()
'DESCRIPTION:Create a 2D frame with supports
Dim arrSupports
arrSupports = Array("Fixed","Pinned")
Begin Dialog UserDialog 600,200,"2D Frame Model" ' %GRID:5,5,1,1
Text 20,20,190,15,"No. of Horizontal Bays:",.Text1
Text 20,45,190,15,"No. of Vertical Bays",.Text2
Text 20,70,190,15,"Vertical Distance",.Text3
Text 20,95,190,15,"Horizontal Distance",.Text4
Text 20,130,190,15,"Support Type",.Text5
TextBox 220,20,130,15,.clmn
TextBox 220,40,130,15,.row
TextBox 220,70,130,15,.ht
TextBox 220,95,130,15,.wdth
DropListBox 240,130,130,50,arrSupports(),.sprt
OKButton 360,165,90,20
CancelButton 490,165,90,20
End Dialog
Dim dlg As UserDialog

The rest of the macro code is unchanged. The selection from the drop-down list is passed as the position in the array selected (e.g., "0" for the first position, "1" for the next position, etc.).

OS. Examples

The following examples have been provided to assist in creating macros using OpenSTAAD in commonly used applications like Microsoft Excel, Autodesk AutoCAD, Microsoft Word.

OS. Simple STAAD.Pro Macro

This example demonstrates a small macro which can be used within STAAD.Pro.

Often, when learning to program, you begin with a program which simply outlines the basic structure of an application, module, or function; typically resulting with a screen message displaying the phrase "Hello World". This example expands upon this to include the foundation from a practical application as well.

Note: Additional examples in this section demonstrate how to poll STAAD data from external programs.

1. Open STAAD.Pro.
2. On the Utilities ribbon tab, select the Macro tool in the Developer group.
The **Macro** dialog opens.

3. Click **Create New**.
   The **New Macro File Name** dialog opens.

4. Type a title of `CreateNewView.vbs` with the following description: *Creates a new view from the selected beams.*
   
   **Note:** You can save the macro file anywhere, so long as the directory has write permission for your user account.

The **STAAD.Pro Script Editor window** (on page 5054) opens with a subroutine title Main.

5. Just after the description, type the following just after the description comment line:

   ```vbs
   Dim objOpenSTAAD As Object
   Dim SelBeamsNo As Long
   Dim SelBeams() As Long
   ```

   This is used to provide some declarations of the objects and variables used in this program.

6. Type the following lines to instantiate the OpenSTAAD object:

   ```vbs
   'Launch the OpenSTAAD Object
   Set objOpenSTAAD = GetObject(,"StaadPro.OpenSTAAD")
   ```

   **Note:** The first line beginning with the apostrophe (') is a comment. It isn't necessary, but it is good practice to add remarks such as this to make your code clear to others (as well as to yourself when you revisit the code at a later time).

7. Type the following lines to set up a logical check for if any beams are selected:

   ```vbs
   'Get no. of selected beams
   SelBeamsNo = objOpenSTAAD.Geometry.GetNoOfSelectedBeams
   If (SelBeamsNo > 0) Then
   ```

   Here, the `GetNoOfSelectedBeams` Geometry function in OpenSTAAD is being used to aid our test. The test is an if... then... else... statement, which continues in the following steps.

8. Type following lines to instruct the program what to do if our statement is true (i.e., there is at least one beam selected).

   That is to create a new view from the active selection using the `CreateNewViewForSelection` View function in OpenSTAAD.

   ```vbs
   ReDim SelBeams(SelBeamsNo) As Long
   'Create a new view
   objOpenSTAAD.View.CreateNewViewForSelections
   ```

9. Type the following lines.

   Since this macro might be run with no beams selected, a message can be provided to the user for some feedback in this instance with the following line:

   ```vbs
   Else
   MsgBox "No beams are currently selected.", vbOkOnly
   End If
   ```

   **Tip:** You could add the message *Hello World*, if you prefer to stick with a more traditional introductory example of programming.
10. Type the following statement to close the instance of the OpenSTAAD object:

   Set objOpenSTAAD = Nothing

This is all it requires to create a macro. Obviously, this particular example really only duplicates the functionality of selecting the **New View** tool in STAAD.Pro. However, it easy to combine other OpenSTAAD functions to automate a series of commonly used features in order to create your own time saving tools.

In this example, for the sake of brevity, the only model entities checked for selection are beams (that is, a new view is only created if beam elements are selected). You could easily expand this to Nodes, Plates, Solids, etc.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

**OS. Microsoft Excel Macro**

A Microsoft Office Excel spreadsheet which can be used to check the capacity of a rectangular concrete beam with the reinforcement already laid out.

This Excel file checks the bending capacity of a rectangular concrete beam with the reinforcement already laid out. The capacity is checked against the maximum sagging moment produced from a series of load cases. The beam is analyzed in STAAD.Pro. The results are extracted and linked into Excel using OpenSTAAD and VBA. A macro name *Exam8* has been created to retrieve the maximum sagging moment along the span of the beam as well as the width and depth of the cross-section of the beam. The maximum sagging moment for each load case is extracted, and the governing moment is the largest compression moment of the maximum moments.

The calculations for checking the capacity are located on the sheet marked “Concrete” while the extraction of the values from STAAD occurs on the sheet marked “STAAD.Pro Output.”

1. Open the file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\OpenSTAAD\Rectangle-Beam.xls.
Note: Excel will warn of macros present in the file. Simply click the Options... button in the Security Warning message area to open the Microsoft Office Security Options dialog, where you will select the Enable this Content option and click OK.

Caution: It is always recommended to do a virus scan on any macro before opening it - including this one!

2. Select the sheet named STAAD.Pro Output and change the values of File Name (cell B14) and Member Number (cell B15) to reflect the file and member number to be considered.

Note: Make sure that there are valid results for the STAAD file selected and they exist in the same directory as the STD file.

3. To run the macro, either:

   select the Macros tool on the Developer tab (Excel 2007 and higher).

   Note: The Developer tab must first be enabled in Excel 2007 and higher. Refer to the Excel help for your version for instructions on how to do this.

   or

   select Tools > Macro > Macros (Excel 2005 and lower).

   or

   press ALT+F8.

   The Macro dialog opens.

   ![Macro dialog in Microsoft Office Excel](image)

   Figure 514: Macro dialog in Microsoft Office Excel

4. Select the macro named Examp8 and click Run to start.

   The values from the STAAD file will automatically be linked into the Excel sheet.

Tip: To see what is going on "under the hood", open the Examp8 macro by clicking Edit from the macro dialog box.

OS. Autodesk AutoCAD® Macro

Writing the Member Section Forces at any Distance Along a Member in AutoCAD® 2000 or higher.

OpenSTAAD can also be used to integrate pre- or post-processing data with AutoCAD® 2000 or higher. AutoCAD® 2000 supports VBA macros with its own exposed set of functions. This example automatically calculates the section forces at any distance along a member from a STAAD file and plots the results in a table as a separate layer. A dialog box was created in AutoCAD using AutoCAD VBA forms. The input box will prompt for the STAAD file name, the member number, the load case and the point along the member (expressed as a fraction of the length) where the section forces are to be determined. The macro returns the section forces (by using OpenSTAAD to read STAAD's database) and plots them in a pre-defined table in the DXF file (STDandAcad.dxf).

1. Open the file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\OpenSTAAD\STDandAcad.dwg.

AutoCAD will warn of macros present in the file.

**Caution:** It is always recommended to do a virus scan on any macro before opening it - including this one!

2. Click Enable Macros.

3. To run the macro, either:

   select the RUN VBA Macro tool on the Manage tab (AutoCAD 2009 and higher).

   **Note:** Microsoft Visual Basic for Applications Module is not installed with recent versions of AutoCAD but can be downloaded from the Autodesk website. Refer to the help included with AutoCAD for more information.

   or

   select Tools > Macro > Macros (previous versions of AutoCAD or when AutoCAD 2009 is in AutoCAD Classic mode).

   or

   press ALT+F8.
The Macro dialog opens.

![Macro dialog in Autodesk AutoCAD 2011](image)

**Figure 515: Macro dialog in Autodesk AutoCAD 2011**

4. Select the macro named `STAADSectionForces` and click **Run**.

The **STAAD.Pro Section Forces** dialog opens. A warning also opens informing you that the STAAD File name must be specified.
5. Enter a valid filename, including complete file path, for the current input file open in STAAD.Pro. The Member Number and Load Case drop-down lists are populated with data from the selected model.

6. Select a Member Number and Load Case and specify a Fraction Along Beam.

7. Click OK. The table is updated.

8. (Optional) To populate the table with different results, first clear all contents on the STAAD Results.

### OS. Microsoft Office Security Options

A Microsoft Office Word document is included which contains a partial report for analysis results which can be used as a basis for a customized report document.

The document file includes a macro named Pro which checks for the number of supported nodes as well as the number of load cases and load combinations and reports these back to the document. The document can then report support reactions for the selected node number and load case number.

1. Open an input file within STAAD.Pro.
2. Open the file C:\Users\Public\Documents\STAAD.Pro CONNECT Edition\Samples\OpenSTAAD\STAADandWord.doc.

**Note:** Word will warn of macros present in the file. Simply click the **Options...** button in the Security Warning message area to open the Microsoft Office Security Options dialog, where you will select the **Enable this Content** option and click **OK**.

**Caution:** It is always recommended to do a virus scan on any macro before opening it - including this one!

3. Click the **Update Nodes and Load Cases** button.

   The **Node Number** and **Load Case Number** selectors update with the data from the selected file.

4. Select the **Node Number** and **Load Case Number** numbers for which results will be retrieved.

5. Click **Get Results**.

   The support reactions and units update in the table below.
OS. Retrieve Dynamic Output

The following example macro uses several OpenSTAAD output functions to build a mode shape report for the results of a dynamic analysis.

```vba
Option Explicit

Sub Main()
