V. United States
V. AASHTO

V. AASHTO 17th Ed ASD - Design Frame

The following compares the solution of a design performed using STAAD.Pro against a hand calculation.

Reference

Related Links

• D1.D.1 AASHTO (ASD) (on page 1170)

Problem

Determine the allowable stresses (AASHTO code) for the members of the structure as shown in figure. Also, perform a code check for these members based on the results of the analysis.

Members 1, 2 = W12X26, Members 3, 4 = W14X43
Members 5, 6, 7 = W16X36, Membr8= L40404,
Member 9 = L50506

The frame is subject to the following load cases:

1. a uniform gravity load along the beam, \( w = 2 \text{ kips/ft} \) (dead + live)
2. a lateral wind load, \( F = 15 \text{ kips} \)
3. a combination of 75% of load 1 and 75% of load 2

Figure 494: AASHTO ASD verification problem
Solution

Only the AASHTO steel design elements are checked here. No structural analysis calculations are included in these hand verifications.

Though the program does check shear per the AASHTO specifications, those calculations are not reflected here. Only the controlling stress ratios are presented.

As all members are grade 36 steel, the following critical slenderness parameter applies to each:

\[ C_c = \sqrt{\frac{2a^2E}{F_y}} = \sqrt{\frac{2\times7.65^2 \times 32,000}{36}} = 126.1 \]

Member 1

Size W 12X26, L = 10 ft, a = 7.65 in, Sz = 33.39 in³

From observation, Load case 1 will govern

- \( F_x = 25.0 \text{ kip (compression)} \)
- \( M_z = 56.5 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

\[ F_{TY} = F_{TZ} = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

Bending Minor Axis

Allowable minor axis bending stress:

\[ F_{cz} = \frac{50(10)^6 C_b}{S_{zc}} \left( \frac{I_{yc}}{I} \right) \sqrt{0.772 \frac{J}{I_{yc}} + 9.87 \left( \frac{d}{l} \right)^2} \leq 0.55 F_Y \]

Where:

\[ C_b = 1.75 + 1.05(M1/M2)+0.3x(M1/M2)^2 \]

\( M1 = 0 \), so \( C_b = 1.75 \)

\( S_{zc} = \text{Section modulus with respect to the compression flange} = 204/(0.5 \times 12.22) = 33.38789 \text{ in}^3 \)

\( I_{YC} = t_b \frac{3}{12} = 0.38 \times 6.49\frac{3}{12} = 8.6564 \text{ in}^4 \)

\( J = (2 \times 6.49 \cdot 0.38^3 + (12.22 - 2 \cdot 0.38) \cdot 0.23^3)/3 = 0.28389 \text{ in}^4 \)

\[ F_{cz} = \frac{50(10)^6 1.75 \left( 8.6564 \right)}{33.38789} \left( \frac{0.772 \cdot 0.28389}{8.6564} + 9.87 \left( \frac{11.46}{120} \right)^2 \right) 10^{-3} = 64.375 \text{ksi} \]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{cz} = 19.8 \text{ ksi} \)

Axial Compression

Critical \( (kL/r) = 1.0 \cdot 120 / 1.5038 = 79.7978 \)

As \( (kL/r) < C_c \), the allow axial stress in compression is given by:

\[ F_a = \frac{F_y}{F.S.} \left[ 1 - (\frac{kL}{r})^2 \frac{F_y}{4n^2E} \right] = \frac{36}{2.12} \left[ 1 - (79.79)^2 \frac{36}{4n^229,000} \right] = 13.58 \text{ksi} \]

Actual Stress
Actual axial stress, \( f_a = \frac{25}{7.65} = 3.26 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress = \( f_{bz} = \frac{56.5 \cdot 12}{33.4} = 1.692 \cdot 12 = 20.3 \text{ ksi} \)

\[
F_{ez} = \frac{\pi^2 E}{F.S.(kL/r)^2} = \frac{\pi^2 29,000}{2.12(120/5.17)^2} = 250.6 \text{ksi}
\]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42

\[
\frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{F_{bz}} + \frac{C_{my} f_{by}}{F_{by}} = \frac{3.26}{13.58} + \frac{0.58 \cdot 20.3}{(1 - 3.26/250.6)19.8} + 0 = 1.122
\]

For the end section, use Equation 10.43:

\[
\frac{f_a}{0.472 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{3.26}{0.472(36)} + \frac{20.3}{19.8} + 0 = 1.217
\]

The critical stress ratio is thus 1.217. The value calculated by STAAD is 1.218

**Member 2**

Size W 12X26, \( L = 5 \text{ ft.}, a = 7.65 \text{ in}^2, Sz = 33.4 \text{ in}^3 \)

From observation Load case 1 will govern, Forces at the midspan are

- \( F_x = 8.71 \text{ kip (compression)} \)
- \( M_z = 56.5 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\( F_{TY} = F_{TZ} = 0.55 \cdot F_Y = 19.8 \text{ ksi} \)

**Bending Major Axis**

\[
F_{ez} = \frac{50(10)^6 C_b}{S_{xc}} \left( \frac{I_{yc}}{T} \right) \sqrt{0.772 \frac{J}{T_{yc}} + 9.87 \left( \frac{d}{T} \right)^2} \leq 0.55 F_Y
\]

Where:

\( C_b = 1.75 + 1.05(M1/M2)+0.3x(M1/M2)^2 \)

\( M1 = 39.44 \) and \( M2 = 677.96, \) so \( C_b = 1.69 \)

\( S_{xc} = \) Section modulus with respect to the compression flange \( = \frac{204}{(0.5 \cdot 12.22)} = 33.38789 \text{ in}^3 \)

\[
I_{YC} = t_b^3/12 = 0.38 \cdot 6.49^3/12 = 8.6564 \text{ in}^4
\]

\[
J = (2 \times 6.49 \cdot 0.38^3 + (12.22 - 2 \cdot 0.38) \cdot 0.23^3)/3 = 0.28389 \text{ in}^4
\]

\[
F_{ez} = \frac{50(10)^6 1.69}{33.38789} \left( \frac{8.6564}{60} \right) \sqrt{0.772 \frac{0.28389}{8.6564} + 9.87 \left( \frac{11.46}{60} \right)^2} 10^{-3} = 227.34 \text{ksi}
\]
which is larger than \(0.55 \cdot F_Y = 19.8 \text{ ksi}\), so \(F_{CZ} = 19.8 \text{ ksi}\)

**Axial Compression**

Critical \((kL/r) = 1.0 \cdot 60/1.504 = 39.92\)

As \((kL/r) < C_c\), the allow axial stress in compression is given by:

\[
F_a = \frac{F_Y}{F.S.} \left[ 1 - \frac{(kL/r)^2 F_Y}{4n^2 E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(39.92)^2}{4 \cdot 29,000} \right] = 16.13 \text{ksi}
\]

**Actual Stress**

Actual axial stress, \(f_a = 8.71 / 7.65 = 1.138 \text{ ksi}\)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress = \(f_{bz} = 56.5 \cdot 12 / 33.4 = 1.691 \cdot 12 = 20.3 \text{ ksi}\)

\((KL/r)_a = 1 \cdot 60/5.16 = 11.618\)

\[
F_{ez} = \frac{a^2 E}{F.S.(KL/r)^2} = \frac{a^2 29,000}{2.12(11.618)^2} = 998.5 \text{ksi}
\]

From Table 10-36A, \(C_{mz} = 0.85\)

Equation 10-42

\[
\frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{(1 - \frac{f_a}{F_a}) F_{bz}} + \frac{C_{by} f_{by}}{(1 - \frac{f_a}{F_a}) F_{by}} = \frac{1.138}{16.13} + \frac{0.58 \cdot 20.3}{19.8} + 0 = 0.942
\]

For the end section, use Equation 10.43:

\[
\frac{f_a}{0.472 F_Y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{1.138}{19.8} + \frac{20.3}{19.8} + 0 = 1.092
\]

The critical stress ratio is thus 1.092. The value calculated by STAAD is 1.093.

**Member 3**

Size W 14X43, \(L = 11 \text{ ft.}, a = 12.6 \text{ in}^2, Sz = 62.7 \text{ in}^3\)

From observation Load case 3 will govern, Forces at the end are

- \(F_X = 25.5 \text{ kip (compression)}\)
- \(M_z = 112.17 \text{ k-ft}\)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\(FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi}\)

**Bending Major Axis**

\[
F_{ez} = \frac{50(10)^6 C_b}{S_{xc}} \left( \frac{I_{yc}}{I} \right) \left( 0.772 \frac{J}{J_{yc}} + 9.87 \left( \frac{d}{r} \right)^2 \right) \leq 0.55 F_Y
\]
Where:

\[ C_b = 1.75 + 1.05 \frac{M_1}{M_2} + 0.3x\left(\frac{M_1}{M_2}\right)^2 \]

\( M_1 = 0 \), so \( C_b = 1.75 \)

\( S_{zc} = \text{Section modulus with respect to the compression flange} = \frac{428}{0.5 \cdot 13.66} = 62.7 \text{ in}^3 \)

\( I_{YC} = \frac{tb^3}{12} = 0.53 \cdot \frac{8.0^3}{12} = 22.61 \text{ in}^4 \)

\( J = (2 \cdot 8.0 \cdot 0.53^3 + (13.66 - 2 \cdot 0.53) \cdot 0.305^3)/3 = 0.913 \text{ in}^4 \)

\( F_{cz} = 50 \left(\frac{10}{6}\right)\left(\frac{1.75}{62.7}\right) = 19.8 \text{ kips} \)

\( S_{zc} = 22.61 \text{ in}^3 \)

\( F_{cy} = 36 \cdot 2.12 = 76.67 \text{ kips} \)

\( F_{ez} = \frac{50(10)6}{62.7}\left(\frac{22.61}{132}\right)\left(\frac{0.772}{22.61}\right) + 9.87 \left(\frac{12.6}{132}\right)^2 10^{-3} = 83.19 \text{ kips} \)

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ kips} \), so \( F_{cz} = 19.8 \text{ kips} \)

**Axial Compression**

Critical \((kL/r) = 1.0 \cdot \frac{132}{1.894} = 69.69 \)

\( \frac{F_a}{F_S} < C_c \), the allowable axial stress in compression is given by:

\[ F_a = F_y \frac{1 - \frac{(kL/r)^2 F_y}{4n^2E}}{1 - \frac{(69.69)^2 36}{4n^2 29,000}} = 14.39 \text{ kips} \]

**Actual Stress**

Actual axial stress, \( f_a = 25.5 / 12.6 = 2.024 \text{ kips} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress = \( f_{bz} = 112.17 \cdot 12/62.7 = 1.789 \cdot 12 = 21.467 \text{ kips} \)

\( (KL/r)_z = 1 \cdot \frac{132}{5.828} = 22.649 \)

\[ F_{ez} = \frac{n^2 E}{F.S.(KL/r)^2} = \frac{n^2 29,000}{2.12(22.648)^2} = 263.18 \text{ kips} \]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42

\[ \frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{F_{bz}} + \frac{C_{my} f_{by}}{F_{by}} = 2.024 + 0.58 \cdot 21.467 + 0 = 1.069 \]

For the end section, use Equation 10.43:

\[ \frac{f_a}{0.472 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = 2.024 + 21.467 + 0 = 1.203 \]

The critical stress ratio is thus 1.203. The value calculated by STAAD is 1.204.

**Member 4**

Size W 14X43, \( L = 4 \text{ ft.}, a = 12.6 \text{ in}^2, Sz = 62.6 \text{ in}^3 \)

From observation Load case 3 will govern, Forces at the end are

- \( F_x = 8.75 \text{ kip (tension)} \)

- \( M_x = 112.17 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\[
FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi}
\]

**Bending Major Axis**

\[
F_{cz} = \frac{50(10)^6 C_b}{S_{xc}} \left( \frac{I_{yc}}{I} \right) \sqrt{0.772 \frac{J}{I_{yc}} + 9.87 \left( \frac{d}{T} \right)^2} \leq 0.55 F_y
\]

Where:

\[
C_b = 1.75 + 1.05(M_1/M_2) + 0.3 \cdot (M_1/M_2)^2
\]

\[
M_1 = -191.36 \text{ Kip-in}, \ M_2 = -1346.08 \text{ Kip-in} \text{ so } C_b = 1.606
\]

\[
I_{yc} = \frac{tb^3}{12} = 0.53 \cdot \frac{8.0^3}{12} = 22.61 \text{ in}^4
\]

\[
J = (2 \cdot 8.0 \cdot 0.53^3 + (13.66 - 2 \cdot 0.53) \cdot 0.305^3)/3 = 0.913 \text{ in}^4
\]

\[
F_{cz} = \frac{50(10)^6 \cdot 1.606}{22.61} \left( \frac{22.61}{48} \right) \sqrt{0.772 \frac{0.911}{22.61} + 9.87 \left( \frac{12.6}{48} \right)^2} 10^{-3} = 508.8 \text{ ksi}
\]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{cz} = 19.8 \text{ ksi} \)

**Axial Tension**

**Note:** No connection information is specified and no reduction of section is assumed.

\[
F_t = 0.55 \cdot F_Y = 19.8 \text{ ksi}
\]

**Actual Stress**

Actual axial stress, \( f_a = 8.75 / 12.6 = 0.694 \text{ ksi} \)

Actual bending stress = \( f_{bz} = 112.17 \cdot 12/62.7 = 1.789 \cdot 12 = 21.47 \text{ ksi} \), which exceeds \( F_{cz} \):

\[
f_{bz}/F_{cz} = 21.47/19.8 = 1.084
\]

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.43 in section 10-36 to calculate the design ratio for the end section.

\[
\frac{f_a}{0.472 F_{y}} + \frac{f_{bz}}{F_{by}} + \frac{f_{by}}{F_{by}} = \frac{0.694}{0.472(36)} + \frac{21.467}{19.8} + 0 = 1.125
\]

The critical stress ratio is thus 1.125. The value calculated by STAAD is 1.126.

**Member 5**

Size W 16X36, \( L = 5 \text{ ft.}, a = 10.6 \text{ in}^2, Sz = 56.5 \text{ in}^3 \)

From observation Load case 3 will govern, Forces at the end are

- \( Fx = 14.02 \text{ kip (compression)} \)
- \( Mz = 57.04 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.
Bending Minor Axis

Allowable minor axis bending stress:

\[ F_{TY} = F_{TZ} = 0.55 \cdot F_Y = 19.8 \text{ ksi} \]

Bending Major Axis

\[ F_{cz} = \frac{50(10)^6 C_b}{S_{zc}} \left( \frac{I_{yc}}{J_{yc}} \right) \left[ 0.772 \frac{J_{zc}}{J_{yc}} + 9.87 \left( \frac{I_{yc}}{I_{zc}} \right)^2 \right] \leq 0.55F_y \]

Where:

\[ C_b = 1.75 + 1.05(M1/M2) + 0.3 \cdot (M1/M2)^2 \]

\[ M1 = 40.14, \quad M2 = -684.4 \quad \text{so} \quad C_b = 1.81 \]

\[ S_{zc} = \text{Section modulus with respect to the compression flange} = \frac{448}{0.5 \cdot 15.86} = 56.5 \text{ in}^3 \]

\[ I_{YC} = \frac{tb^3}{12} = 0.43 \cdot \frac{6.99^3}{12} = 12.238 \text{ in}^4 \]

\[ J = (2 \cdot 6.99 \cdot 0.43^3 + (15.86 - 2 \cdot 0.43) \cdot 0.29^3)/3 = 0.5 \text{ in}^4 \]

\[ F_{cz} = \frac{50(10)^6 \cdot 1.81}{56.5} \left( \frac{12.238}{60} \right) \left[ 0.772 \frac{0.5}{12.238} + 9.87 \left( \frac{15}{60} \right)^2 \right] 10^{-3} = 263.1 \text{ ksi} \]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{CZ} = 19.8 \text{ ksi} \)

Axial Compression

Critical \((kL/r) = 1.0 \cdot 60/1.52 = 69.69\)

As \((kL/r) < C_c\), the allow axial stress in compression is given by:

\[ F_a = \frac{F_y}{F.S.} \left[ 1 - \frac{(kL/r)^2 F_y}{4n^2 E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(39.474)^2}{4n^2 29,000} \right] = 16.15 \text{ ksi} \]

Actual Stress

Actual axial stress, \( f_a = 14.02 / 10.6 = 1.323 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress \( f_{bz} = 57.04 \cdot 12 / 56.5 = 1.001 \cdot 12 = 12.115 \text{ ksi} \)

\( (KL/r)_2 = 1 \cdot 60/6.5 = 9.231 \)

\[ F_{ez} = \frac{n^2 E}{F.S.(kL / r)^2} = \frac{n^2 29,000}{2.12(9.231)^2} = 1, 584.4 \text{ ksi} \]

From Table 10-36A, \( C_{mz} = 0.85 \)

Equation 10-42

\[ \frac{f_a}{F_a} + \frac{C_{mz} f_{bz}}{F_{bz}} + \frac{C_{my} f_{by}}{F_{by}} = \frac{1.323}{16.149} + \frac{0.85 \cdot 12.115}{1, 584.4} + 0 = 0.602 \]

For the end section, use Equation 10.43:
\[
\frac{f_a}{0.472 F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{1.323}{0.472(36)} + \frac{12.115}{19.8} + 0 = 0.689
\]

The critical stress ratio is thus 0.689. The value calculated by STAAD is 0.690.

**Member 6**

Size W 16X36, L = 16 ft., a = 10.6 in², Sz = 56.5 in³

From observation Load case 3 will govern, Forces at the end are

- \( F_x = 10.2 \text{ kip (compression)} \)
- \( M_z = 62.96 \text{ k-ft} \)

Calculate the allowable stress as per Table 10.32.1A.

**Bending Minor Axis**

Allowable minor axis bending stress:

\[
FTY = FTZ = 0.55 \cdot F_Y = 19.8 \text{ ksi}
\]

**Bending Major Axis**

\[
F_{cz} = \frac{50(10)^6 C_b}{S_{xc}} \left( \frac{I_{yc}}{I} \right)^{0.772} \left( \frac{J}{I_{yc}} \right)^2 + 9.87 \left( \frac{J}{I_{yc}} \right)^2 \leq 0.55 F_y
\]

Where:

\[
C_b = 1.75 + 1.05(M1/M2) + 0.3 \cdot (M1/M2)^2
\]

\[
M1 = 8.947 \quad M2 = 183.05 \quad \text{so} \quad C_b = 1.69
\]

\[
S_{xc} = \text{Section modulus with respect to the compression flange} = 448/(0.5 \cdot 15.86) = 56.5 \text{ in}^3
\]

\[
I_{YC} = tb^3/12 = 0.43 \cdot 6.99^3/12 = 12.238 \text{ in}^4
\]

\[
J = (2 \cdot 6.99 \cdot 0.43^3) + (15.86 - 2 \cdot 0.43) \cdot 0.29^3/3 = 0.5 \text{ in}^4
\]

\[
F_{cz} = \frac{50(10)^6 \cdot 1.81}{56.5} \cdot \left( \frac{12.238}{192} \right)^{0.772} \cdot \frac{0.5}{12.238} + 9.87 \left( \frac{15}{192} \right)^2 \cdot 10^{-3} = 287.9 \text{ ksi}
\]

which is larger than \( 0.55 \cdot F_Y = 19.8 \text{ ksi} \), so \( F_{cz} = 19.8 \text{ ksi} \)

**Axial Compression**

Critical \((kL/r) = 1.0 \cdot 192/1.52 = 126.3\)

As \((kL/r) > C_c\), the allow axial stress in compression is given by:

\[
F_a = \frac{\pi^2 E}{F.S.(kL/ r)^2} = \frac{\pi^2 29,000}{2.12(126.3)^2} = 8.46 \text{ksi}
\]

**Actual Stress**

Actual axial stress, \( f_a = 10.2 / 10.6 = 0.962 \text{ ksi} \)

The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.42 in section 10-36 to calculate the design ratio.

Actual bending stress \( f_{bz} = 62.96 \cdot 12 / 56.5 = 1.114 \cdot 12 = 13.37 \text{ ksi} \)
\[(KL/r)_{2} = 1 \cdot 192/6.51 = 29.49\]

\[F_{ez} = \frac{n^{2}E}{F.S.(kL/r)^{2}} = \frac{n^{2}29,000}{2.12(29.49)^{2}} = 155.2\text{ksi}\]

From Table 10-36A, \(C_{mz} = 0.85\)

Equation 10-42

\[
\frac{f_{a}}{F_{a}} + \frac{C_{mz}f_{bz}}{F_{bz}} + \frac{C_{my}f_{by}}{F_{by}} = \frac{0.962}{8.46} + \frac{0.85 \cdot 13.37}{(1-0.926)19.8} + 0 = 0.691
\]

For the end section, use Equation 10.43:

\[
\frac{f_{a}}{0.472F_{y}} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{0.962}{0.472(36)} + \frac{13.37}{19.8} + 0 = 0.732
\]

The critical stress ratio is thus 0.732. The value calculated by STAAD is 0.732

**Note:** The program gives this value when the slenderness check is suppressed (MAIN 1.0 for member 6); otherwise the member fails as a compression member with a slenderness parameter greater than 120).

**Member 7**

Size W 16X36, L = 4 ft., a = 10.6 in\(^2\), Sz = 56.5 in\(^3\)

From observation Load case 3 will govern, Forces at the midspan are

- \(F_x = 24.05\) kip (tension)
- \(M_z = 62.96\) k-ft

Calculate the allowable stress as per Table 10.32.1A

**Bending Minor Axis**

Allowable minor axis bending stress:

\[FT_{Y} = FT_{Z} = 0.55 \cdot F_{Y} = 19.8\text{ ksi}\]

**Bending Major Axis**

\[FC_{Z} = 0.55 \cdot F_{Y} = 19.8\text{ ksi}\]

**Axial Tension**

**Note:** No connection information is specified and no reduction of section is assumed.

\[F_a = 0.55 \cdot F_Y = 19.8\text{ ksi}\]

**Actual Stress**

Actual axial stress, \(f_a = 24.05/10.6 = 2.268\text{ ksi}\), hence, ok.

Actual bending stress = \(f_{bz} = 62.96 \cdot 12/56.5 = 1.114 \cdot 12 = 13.37\text{ ksi}\)

So the combined ratio is

\[
\frac{f_{a}}{F_{a}} + \frac{f_{bz}}{F_{TZ}} + \frac{f_{by}}{F_{TY}} = 2.268/19.8 + 13.37/19.8 + 0 = 0.790
\]
The critical moment occurs at the end node of the beam. So we use the AASHTO equation 10.43 in section 10-36 to calculate the design ratio for the end section.

\[
\frac{f_a}{0.472F_y} + \frac{f_{bz}}{F_{bz}} + \frac{f_{by}}{F_{by}} = \frac{2.268}{2.12} + \frac{13.73}{19.8} + 0 = 0.809
\]

The critical stress ratio is thus 0.809. The value calculated by STAAD is 0.809.

**Member 8**

Size L4x4x1/4, L = 7.07 ft, a = 1.938 in²

From observation Load case 1 will govern, Forces

\( F_x = 23.04 \text{ kip (compression)} \)

Calculate the allowable stress as per Table 10.32.1A

**Axial Compression**

Critical \((KL/r)_y = 1.0 \cdot 7.07 \cdot 12 / 0.795 = 106.7 \)

As \((kL/r) < C_c\), the allow axial stress in compression is given by:

\[
F_a = \frac{F_y}{F.S.} \left[ 1 - \frac{(kL/r)^2F_y}{4\pi^2E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(106.7)^2}{4\pi^229,000} \right] = 10.89 \text{ksi}
\]

**Actual Stress**

Actual axial stress, \( f_a = 23.04 / 1.938 = 11.88 \text{ ksi} \)

\( f_a / F_a = 11.88 / 10.89 = 1.091 \)

The value calculated by STAAD is 1.091.

**Member 9**

Size L5x5x3/8, L = 5.657 ft, A = 3.61 in²

From observation Load case 1 will govern, Forces

\( F_x = 48.44 \text{ kip (compression)} \)

Calculate the allowable stress as per Table 10.32.1A

**Axial Compression**

Critical \((KL/r)_y = 1.0 \cdot 5.657 \cdot 12 / 0.99 = 68.57 \)

As \((kL/r) < C_c\), the allow axial stress in compression is given by:

\[
F_a = \frac{F_y}{F.S.} \left[ 1 - \frac{(kL/r)^2F_y}{4\pi^2E} \right] = \frac{36}{2.12} \left[ 1 - \frac{(68.57)^2}{4\pi^229,000} \right] = 14.47 \text{ksi}
\]

**Actual Stress**

Actual axial stress, \( f_a = 48.44 / 3.61 = 13.42 \text{ ksi} \)

\( f_a / F_a = 13.42 / 14.47 = 0.927 \)

The value calculated by STAAD is 0.928.

V. AASHTO 2nd Ed LRFD - Design Beam

The following compares the solution of a design performed using STAAD.Pro against a hand calculation of steel design per the AASHTO (LRFD) code.

Details

Determine the allowable resistances (AASHTO LRFD, 1998 code) for the member of the structure as shown in figure. Also, perform a code check for the member based on the results of the analysis.

A 48 foot long, non-composite girder is assumed to be simply supported. The section is a plate girder with 16" x 1" plate flanges and a 34" x 3.6" plate web (36 in. total depth). All plates are grade 36 steel.

The beam is subject to a 9.111 kip/ft uniform load.

Validation

\[ A = 154.4 \text{ in}^2, I_z = 21,594 \text{ in}^4, I_y = 814.9 \text{ in}^4 \]
\[ S_z = 21,594(2)/36 = 1,200 \text{ in}^3 \]
From observation Load case 1 will govern,

\[ M_z = 2,624 \text{ kip-ft} \]

**Axial Compression Capacity**

Refer Clause 6.9.4 of the code.

\((kL/r)_{y} = 0.333 \times 576 / 2.297 = 83.50\)

\((kL/r)_{z} = 1 \times 576 / 11.826 = 48.71\)

\((kL/r)_{\text{crit}} = 83.50 < 120, \text{ ok.}\)

Calculation of Width /Thickness ratio for axial compression

Plate buckling coefficients taken from Table 6.9.4.2-1:

\( k_w = 1.49, \ k_f = 0.56\)

Slenderness ratio for the web:

\( (d - 2 \cdot t_f) / t_w = (36 - 2 \cdot 1) / 3.6 = 9.444\)

Slenderness ratio for the 1/2 flange:

\( b_f / (2 \cdot t_f) = 16 / (2 \cdot 1) = 8.0\)

Critical ratio for web:

\[ k_w \sqrt{\frac{E}{F_y}} = 1.49 \sqrt{\frac{29,000}{36}} = 42.29 > 9.444\]

Critical ratio for flange:

\[ k_f \sqrt{\frac{E}{F_y}} = 0.56 \sqrt{\frac{29,000}{36}} = 15.89 > 8.0\]

Thus, **OK** [AASHTO LRFD Cl. 6.4.9.2]

Slenderness ratio about major and minor axis:

\( \lambda_{z} = \left( \frac{Kl}{r_z A} \right)^2 \frac{F_y}{E} = \left( \frac{1.0 \cdot 576}{11.83a} \right)^2 \frac{36}{29,000} = 0.298\)

\( \lambda_{y} = \left( \frac{Kl}{r_y A} \right)^2 \frac{F_y}{E} = \left( \frac{0.333 \cdot 576}{2.36a} \right)^2 \frac{36}{29,000} = 0.877\)

\( \lambda_{y} \) governs, thus \( \lambda = 0.877\)

\( \lambda < 2.25, \text{ so Equation } 6.9.4.1-1 \text{ is used to determine the nominal compressive resistance }\)

\[ P_n = 0.66^3 F_y A_s = 0.66^{0.877} \cdot 36 \cdot 154.4 = 3,861 \text{ kips}\]

The factored compressive resistance, \( P_r = \varphi_c P_n = 0.9 \cdot 3,861 = 3,475 \text{ kips}\)
**Major Axis Bending Capacity**

The compression flange moment of inertia:

\[ I_{yc} = 1(16)^3/12 = 341.3 \text{ in}^4 \]

\[ I_{yc}/I_y = 341.3/814.9 = 0.419, > 0.1 \text{ and } < 0.9 \]

Thus, **OK** [AASHTO LRFD Cl. 6.10.2.1]

\[ 2D_o/t_w = \frac{2(17)}{3.6} = 9.445 < 6.77\sqrt{\frac{E}{F_y}} = 6.77\sqrt{\frac{29,000}{36}} = 192.1 \]

Thus, **OK** [AASHTO LRFD Cl. 6.10.2.2]

Calculation of depth of the web in compression at the plastic moment, \(D_{cp}\) (Clause 6.10.3.3.2)

Area of Web, \(A_w = (36 - 2 \times 1) \times 3.6 = 122.4 \text{ in}^2\)

Area of flange area in tension, \(A_{ft} = \text{Area of flange in compression, } A_{fc} = 16 \times 1 = 16 \text{ in}^2\)

\[ D_{cp} = \left( \frac{D_w}{2A_{ft}} \right) F_y \left( A_{ft} + A_w - A_{fc} \right) = \left( \frac{34}{2 \cdot 122.4 \cdot 36} \right) 36 \left( 16 + 122.4 - 16 \right) = 17 \text{ in} \]

\[ 2D_{cp}/t_w = \frac{2(17)}{3.6} = 9.445 < 3.76\sqrt{\frac{E}{F_y}} = 3.76\sqrt{\frac{29,000}{36}} = 108.1 \]

Thus, **OK** [AASHTO LRFD Cl. 6.10.4.1.2]

\[ \frac{b_f}{t_f} = \frac{16.0}{21.0} = 0.80 < 0.382\sqrt{\frac{E}{F_y}} = 0.382\sqrt{\frac{29,000}{36}} = 10.98 \]

Thus, **OK** [AASHTO LRFD Cl. 6.10.4.3]

Check clause 6.10.4.1.6a

\( (B/t)_{\text{flange}} < 0.75 \times (B/t)_{\text{flange limit}} = 0.75 \times 10.978 \)

\( (D/T)_{\text{web}} < 0.75 \times (D/T)_{\text{web limit}} = 0.75 \times 108.057 \)

Check clause 6.10.4.1.7

\[ M_{pz} = P_z \times F_y = 1,600 \text{ in}^3(36 \text{ ksi}) = 57,614 \text{ in-k} \]

\[ L_b = 0.124 - 0.0759 \left[ M_I/M_{pz} \right] \left( \frac{F_y}{E} \right) = 0.124 - 0.0759 \left( \frac{57,614}{57,614} \right) \left( \frac{2.30(29,000)}{36} \right) = 229.5 \text{ in.} \]

 Unsupported length, \(L_u = 576 \text{ in} > L_b\); section is non-compact.

Check clause 6.10.4.1.9

A notional section comprised of the compression flange and one-third of the depth of the web in compression, taken about the vertical axis.

\[ A_{rt} = A_{cf} + \left( \frac{c - t_f}{3} \right) t_w = 16 + \left( \frac{18 - 1.0}{3} \right) 3.6 = 36.4 \text{ in}^2 \]

\[ I_{rt} = t_f \left[ \left( \frac{c - t_f}{3} \right) \left( \frac{t_w}{12} \right)^3 \right] = 1\left[ \left( \frac{18 - 1}{3} \right) \left( \frac{3.6}{12} \right)^3 \right] = 363.4 \text{ in}^4 \]
Verification Examples

V.09 Steel Design

\[ r_{rt} = \sqrt{\frac{363.4}{36.4}} = 3.149\text{in} \]

\[ L_p = 1.76 \left( 3.159 \right) \sqrt{\frac{29,000}{36}} = 159.8\text{in} \]

\( L_b > L_p \)

Clause 6.10.4.2.6

\[ L_r = 4.44 \left( \frac{I_{yc}}{S_{xc}} \right) \frac{E}{F_y} = 4.44 \sqrt{\frac{341.3 (36) 29,000}{1,200 36}} = 403.3\text{in} \]

Minimum radius of gyration of the compression flange taken about the vertical axis:

\[ r_t = \sqrt{\frac{I_{yc}}{A_{cf}}} = \sqrt{\frac{341.3}{16}} = 4.619\text{in} \]

Hybrid factor, \( R_h = 1.0 \) (For Homogeneous sections, Hybrid factors shall be taken as 1.0 per clause 6.10.4.3.1)

As per clause 6.10.4.3.2, Load-shedding factor, \( R_b \)

If area of the compression flange, \( A_{cf} \geq \) the area of the tension flange, \( A_{tf} \)

\( l_b = 5.76 \)

\( D_c = 17.00 \)

\[ \frac{2D_c}{t_w} = \frac{2(17)}{3.6} = 9.445 < L_b \sqrt{\frac{E}{F_y}} = 5.76 \sqrt{\frac{29,000}{36}} = 163.5 \]

Thus:

\[ R_{b,comp} = R_{b,ten} = 1.0 \]

\( L_r < L_b \)

\[ C_b = 1.75 + 1.05 (M1/M2) + 0.3x(M1/M2)^2 \]

Here \( M1 = 0, M2 = 0 \) so \( C_b = 1.75 \)

\[ M_{nz,comp} = C_b R_{b,comp} R_h \left( \frac{L_r}{L_b} \right)^2 \]

\[ M_{nz,ten} = R_{b,ten} R_h F_y Z \]

\[ M_{nz} = 19,000 \text{kip in} \]

Resisting Moment

\[ M_t = Q_f \cdot M_n = 1.0 (19,000) = 19,000 \text{kip in} \]

Actual Moment = 31,488 kip-in

Interaction ratio = 31,488 / 19,000 = 1.657
**Comparison**

V. AISC

V.AISC 360-16 Angle F.11A

Verify the available flexural strength of a single angle member per AISC 360-16.

References

**Related Links**
- **D1.A.5.3 Flexural Design Strength** (on page 1086)

**Details**

Verify the bending capacity of a single L4x4x1/4. The member is used as a 6 ft simple span subject to a uniform dead load of 0.05 kip/ft and a uniform live load of 0.15 kip/ft. The vertical leg of the single angle is up with the toe in compression. The material is ASTM A36.

**Validation**

**Note:** When assigning the angle, it should be given in a beta angle as the geometrical axis and principal axis are different, and in STAAD.Pro the calculation is done with reference with the principal axis. To match the geometric axis used in AISC 360-16, a BETA angle is assigned to the member in STAAD.Pro.

The nominal flexural strength, $M_n$, shall be the lowest value obtained to the limit states of yielding (plastic moment), lateral-torsional buckling, and leg local buckling.

Ultimate load (for LRFD):

$$w_{ux} = 1.2(0.05) + 1.6(0.15) = 0.30 \text{ kip/ft}$$

$$M_{ux} = w_{ux}L^2/8 = (0.30)(6)^2/8 = 1.35 \text{ kip·ft}$$

Service level load (for ASD):

$$w_{ax} = 0.05 + 0.15 = 0.20 \text{ kip/ft}$$

$$M_{ax} = w_{ax}L^2/8 = (0.20)(6)^2/8 = 0.90 \text{ kip·ft}$$

**Note:** Only bending about the major axis is compared as bending due to loads is about the geometrix X-X axis.

**Yielding**

The nominal flexural strength in the limit state of flexural yielding is:

$$M_n = 1.5M_y = 1.5F_yS_x$$

$$M_n = 1.5(36 \text{ ksi})(1.03 \text{ in}^3) = 55.6 \text{ in·kip}$$

**(Eq. F10-1)**

**Lateral Torsional Buckling**

For single angles bending about a geometric axis with no lateral-torsional restraint:

$$M_y = 0.8F_yS_x$$

$$M_y = 0.8(36 \text{ ksi})(1.03 \text{ in}^3) = 29.7 \text{ in·kip}$$

**(F10-2)**

For bending about one of the geometric axes of an equal-leg angle without axial compression, no lateral-torsional restraint, and with maximum compression in the toe:

$$M_{cr} = \frac{0.58Eb^4C_b}{L_b^2}\left[\sqrt{1 + 0.88\left(\frac{L_bC_b}{L_b^2}\right)^2} - 1\right]$$

**(Eq. F10-5a)**

where

$$C_b = 1.14 \text{ from AISC Table 3-1 Manual}$$
\[
M_{cr} = \frac{0.58(29,000 ksi)(4.0 \text{ in})^4(0.25 \text{ in})^{1.14}}{(6 \text{ ft} \times 12 \text{ in} / \text{ ft})^2} \left(1 + 0.88 \left[\frac{(6 \text{ ft} \times 12 \text{ in} / \text{ ft})(0.25 \text{ in})^2}{(4.0 \text{ in})^2}\right] \cdot 1\right) = 107 \text{ in} \cdot \text{kips}
\]

\[
M_y / M_{cr} = \frac{29.7}{107} = 0.278 < 1.0; \text{ therefore, AISC eq. F 10-2 is applicable:}
\]

\[
M_n = \left(1.92 - 1.17 \sqrt{\frac{M_y}{M_{cr}}}\right) M_y \leq 1.5 M_y
\]

Eq. F10-2

\[
M_n = \left(1.92 - 1.17 \sqrt{\frac{29.7}{107}}\right)29.7 = 38.7 \text{ in} \cdot \text{kip} < 1.5(29.7) = 44.6 \text{ in} \cdot \text{kip}
\]

**Leg Local Buckling**

AISC section F10.3 applies when the toe of the leg is in compression. Check the slenderness of the leg in compression:

\[
\lambda = \frac{b}{t} = \frac{4.0}{0.25} = 16.0
\]

Determine the compact and noncompact slenderness ratios from Table B4.1b, Case 12:

\[
\lambda_p = 0.54 \sqrt{\frac{E}{F_y}} = 0.54 \sqrt{\frac{29,000}{36}} = 15.3
\]

\[
\lambda_r = 0.91 \sqrt{\frac{E}{F_y}} = 0.91 \sqrt{\frac{29,000}{36}} = 25.8
\]

\[
\lambda_p < \lambda < \lambda_r, \text{ therefore the leg is noncompact in flexure.}
\]

\[
S_c = 0.80 S_x = 0.80 (1.03 \text{ in}^3) = 0.824 \text{ in}^3
\]

**Available Flexural Strength**

The lateral-torsional buckling limit state governs.

\[
M_n = 38.7 \text{ in} \cdot \text{kip} = 3.23 \text{ ft} \cdot \text{kip}
\]

**LRFD**

\[
\phi_b = 0.90
\]

\[
\phi_b M_n = 0.90(3.23) = 2.91 \text{ ft-kip} > 1.35 \text{ kip ft}
\]

**ASD**

\[
\Omega_b = 1.67
\]

\[
M_n / \Omega_b = 3.23 / 1.67 = 1.93 \text{ ft-kip} > 0.90 \text{ kip ft}
\]

*** DESIGN MESSAGES ***:
************************
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16 design results are reported in AISC 360-16 code axis convention.

AISC Spec. | STAAD.Pro | Description
---------- | ---------- | ---------------
X          | Z          | Axis typically parallel to the sections principal major axis.
Y          | Y          | Axis typically parallel to the sections principal minor axis.
Z          | X          | Longitudinal axis perpendicular to the cross section.
Verificaton Examples
V.09 Steel Design

| Pz | FX | Axial force. |
| Vy | FY | Shear force along minor axis. |
| Vx | FZ | Shear force along major axis. |
| Tz | MX | Torsional moment. |
| My | MY | Bending moment about minor axis. |
| Mx | MZ | Bending moment about major axis. |

** *** DESIGN MESSAGES ***: **

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

** *** ABBREVIATIONS ***: **

F-T-B = Flexural-Torsional Buckling
L-T-B = Lateral-Torsional Buckling
F-L-B = Flange Local Buckling
W-L-B = Web Local Buckling
L-L-B = Leg Local Buckling
C-F-Y = Compression Flange Yielding
T-F-Y = Tension Flange Yielding

V.AISC 360-16 C Flex Mem F.2-1A

Verify the flexural yielding capacity of a continuously braced channel member subject to major axis bending per AISC 360-16.

References

2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017, pp.F-16 – F-17., Example F.2-1A

Related Links

- D1.A.5.3 Flexural Design Strength (on page 1086)
**Details**

Verify the bending capacity of a C15x33.9. The member is used as a 25 ft simple span subject to a uniform dead load of 0.23 kip/ft and a uniform live load of 0.69 kip/ft. The member is continuously braced. The material is ASTM A36.

**Validation**

Ultimate load (for LRFD):

\[
\begin{align*}
w_u &= 1.2(0.23) + 1.6(0.6) = 1.38 \text{ kip/ft} \\
M_u &= w_u L^2/8 = (1.38)(25)^2/8 = 108 \text{ kip·ft}
\end{align*}
\]

Service level load (for ASD):

\[
\begin{align*}
w_a &= 0.23 + 0.39 = 0.92 \text{ kip/ft} \\
M_a &= w_a L^2/8 = (0.92)(25)^2/8 = 71.9 \text{ kip·ft}
\end{align*}
\]

**Note:** Per the User Note in AISC *Specification* Section F2, all ASTM A36 channel shapes are compact.

**Yielding Limit State**

\[
\begin{align*}
M_n &= M_p = F_y Z_x \\
M_n &= (36 \text{ ksi})(50.8 \text{ in}^3) = 1,830 \text{ in·kip} = 152.5 \text{ ft·kip}
\end{align*}
\]

**Available Flexural Strength**

A continuously braced channel section is governed by the yielding limit state.

LRFD

\[
\begin{align*}
\phi_b &= 0.90 \\
\phi_b M_n &= 0.90(152.5) = 137 \text{ ft·kip} > 108 \text{ kip·ft}
\end{align*}
\]

ASD

\[
\begin{align*}
\Omega_b &= 1.67 \\
M_n/\Omega_b &= 152.5/1.67 = 91.3 \text{ ft·kip} > 71.9 \text{ kip·ft}
\end{align*}
\]

*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations and axes labels as defined in the AISC 360-16 code. The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16 design results are reported in AISC 360-16 code axis convention.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆ about ◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆ along ◆ the axis.

E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

Verify the flexural capacity of a channel member with bracing at ends and fifth points per AISC 360-16.

References

Related Links

- D1.A.5.3 Flexural Design Strength (on page 1086)

Details

Verify the bending capacity of a C15x33.9. The member is used as a 25 ft simple span subject to a uniform dead load of 0.23 kip/ft and a uniform live load of 0.69 kip/ft. The member is braced at the supports and at fifth points. The material is ASTM A36.

Validation

Ultimate load (for LRFD):

\[ w_u = 1.2(0.23) + 1.6(0.6) = 1.38 \text{ kip/ft} \]
\[ M_u = w_uL^2/8 = (1.38)(25)^2/8 = 108 \text{ kip·ft} \]

Service level load (for ASD):

\[ w_a = 0.23 + 0.39 = 0.92 \text{ kip/ft} \]
\[ M_a = w_aL^2/8 = (0.92)(25)^2/8 = 71.9 \text{ kip·ft} \]

Note: Per the User Note in AISC Specification Section F2, all ASTM A36 channel shapes are compact.

From the AISC Manual Table 3-8, for a C15x33.9:

\[ L_p = 3.75 \text{ ft} \]
\[ L_r = 14.5 \text{ ft} \]

The unbraced length of the member:

\[ L = 25.0/5 = 5 \text{ ft} \]

For a compact channel with \( L_p < L_b \leq L_r \), the lesser of the flexural yielding or inelastic lateral-torsional buckling limit states will govern the available flexural strength.

Lateral-Torsional Buckling Limit State

\[ M_n = M_p = F_y Z_x \]  
\[ M_n = (36 \text{ ksi})(50.8 \text{ in}^3) = 1,830 \text{ in·kip = 152 ft·kip} \]

The nominal flexural strength in the lateral-torsional buckling limit state is:

\[ M_n = C_b \left( M_p \cdot \left( M_p \cdot 0.75F_y S_x \left( \frac{L_b \cdot L_p}{L_r \cdot L_p} \right) \right) \right) \leq M_p \]  

where
\[ C_b = 1.0 \text{ for the center segment of a uniformly loaded beam braced at ends and fifth points.} \]

\[ M_n = 1.0 \left\{ \frac{1,830 - 0.75(36)(42.0)}{14.5 - 3.75} \right\} = 1,740 \text{ in} \cdot \text{kip} \]

\[ M_n = 145 \text{ ft} \cdot \text{kip} \]

**Available Flexural Strength**

By observation, the section is governed by the lateral-torsional buckling limit state.

**LRFD**

\[ \phi_b = 0.90 \]
\[ \phi_b M_n = 0.90 \times 145 = 131 \text{ ft-kip} > 108 \text{ kip ft} \]

**ASD**

\[ \Omega_b = 1.67 \]
\[ \frac{M_n}{\Omega_b} = \frac{145}{1.67} = 86.8 \text{ ft-kip} > 71.9 \text{ kip ft} \]

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 HSST Compact Flange F.6

Verify the flexural strength of a square HSS flexural member with compact flanges per the AISC 360-16 code.

References

Related Links

• D1.A.5.3 Flexural Design Strength (on page 1086)

Details

Verify the bending capacity of a HSST 3.5x3.5x1/8. The member is used as a 7.5 ft simple span subject to a uniform dead load of 0.145 kip/ft and a uniform live load of 0.435 kip/ft. The member is continuously braced. The material is ASTM A500 Grade C \( (F_y = 50 \text{ ksi}) \).

Validation

Ultimate load (for LRFD):
\[ \begin{align*}
  w_u &= 1.2(0.145) + 1.6(0.435) = 0.87 \text{ kip/ft} \\
  M_u &= w_u L^2/8 = (0.87)(7.5)^2/8 = 6.12 \text{ kip ft}
\end{align*} \]

Service level load (for ASD):
\[ \\
  w_a &= 0.145 + 0.435 = 0.58 \text{ kip/ft} \\
  M_a &= w_a L^2/8 = (0.58)(7.5)^2/8 = 4.08 \text{ kip ft}
\]

From the AISC Manual Table 3-13:

LRFD
\[ \phi_b M_n = 7.21 \text{ ft k} \]

ASD
\[ M_u/\Omega_b = 4.79 \text{ ft k} \]

However, this does not account for using the design wall thickness for calculating the slenderness ratio for the flange local buckling as per section B4.2.

\[ b_t = \frac{[3.5 - 3\times(0.93\times0.125)]}{(0.93\times0.125)} = 27.1 \]

\[ \lambda_p = 1.12\sqrt{\frac{E}{F_y}} = 1.12\sqrt{\frac{29,000}{50}} = 26.97 < 27.1 \]

**Note:** STAAD.Pro uses the design wall thickness for this calculation and thus considers the section as non-compact.

\[ M_p = Z\times F_y = 1.93\times50 = 96.5 \text{ in k = 8.04 ft k} \]

For non-compact sections:

\[ M_n = M_p - \left( M_p - F_y S \right) \left( 3.57 \frac{b_t}{I_f} \sqrt{\frac{F_y}{E}} - 4.0 \right) \leq M_p \quad [\text{Eqn. F7.2}] \]

\[ M_n = 96.5 - \left( 96.5 - 50 \times 1.66 \right) \left( 3.57 \times 27.1 \sqrt{\frac{50}{29,000}} - 4.0 \right) = 96.27 \text{ in k = 8.02 ft k} \]

LRFD
\[ \phi_b M_n = 7.22 \text{ ft k} \]

ASD
\[ M_u/\Omega_b = 4.80 \text{ ft k} \]

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** ABBREVIATIONS ***:

- Allowable Slenderness Ratio: 300.000

---

### DESIGN MESSAGES

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   
   **Example:** 
   Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 HSST NonCompact Flange F.7

Verify the available flexural strength of a Rectangular HSS flexural member with non-compact flanges per the AISC 360-16 code.

References
2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017, pg F-34 – F-36, Example F.7B

Related Links
• D1.A.5.3 Flexural Design Strength (on page 1086)

Details
Verify the bending capacity of a HSST 10x6x3/16. The member is used as a 21 ft simple span subject to a uniform dead load of 0.15 kip/ft and a uniform live load of 0.4 kip/ft. The member is braced at end points only. The material is ASTM A500 Grade C ($F_y = 50 ksi$).

Validation
Ultimate load (for LRFD):
\[ w_u = 1.2(0.15) + 1.6(0.4) = 0.82 \text{ kip/ft} \]
\[ M_u = w_u L^2/8 = (0.82)(21)^2/8 = 45.2 \text{ kip ft} \]

Service level load (for ASD):
\[ w_a = 0.15 + 0.4 = 0.55 \text{ kip/ft} \]
\[ M_a = w_a L^2/8 = (0.55)(21)^2/8 = 30.3 \text{ kip·ft} \]

Flange slenderness ratio
\[ \lambda = b/t_f = 31.5 \text{ (From Reference 1, Table 1-11)} \]
\[ \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{50}} = 27.0 \]
\[ \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{50}} = 33.7 \]

\[ \lambda_p < \lambda < \lambda_r \] therefore, the flange is non-compact.

Web slenderness ratio:
\[ \lambda = h/t_f = 54.5 \text{ (From Reference 1, Table 1-11)} \]
\[ \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{50}} = 58.3 \]

\[ \lambda < \lambda_p \] therefore, the web is compact (limit state of web local buckling need not be checked).

Flange Local Buckling
\[ M_p = F_y Z_x = 50 \times 18.0 = 900 \text{ in} \cdot \text{k} = 75 \text{ ft} \cdot \text{k} \]

For non-compact sections:
\[ M_n = M_p \left( 1 - \left( M_p - F_y S \right) \frac{3.57 b}{t_f} \frac{F_y}{E} - 4.0 \right) \leq M_p \] \[ \text{[Eqn. F7-2]} \]
\[ M_n = 900 - (900 - 50 \times 14.9)(3.57 \times 31.5 \frac{50}{29,000} - 4.0) = 796 \text{ in} \cdot \text{k} = 66.4 \text{ ft} \cdot \text{k} \]

Yielding and Lateral-Torsional Buckling
\[ L_b = 21 \text{ ft} = 252 \text{ in} \]
\[ L_p = 0.13 E r_y \frac{\sqrt{A_g}}{M_p} = 0.13(29,000)(2.52) \frac{\sqrt{13.8 \times 5.37}}{900} = 210 \text{ in} \]
\[ L_p = 2 E r_y \frac{\sqrt{A_g}}{M_p} = 2(29,000)(2.52) \frac{\sqrt{13.8 \times 5.37}}{900} = 5,580 \text{ in} \]

The moment at the quarter and three-quarter points on a simply supported beam under uniform distributed load (Table 3-23, Case 1 in Reference 1) is \[ 3/32wl^2 \], which is simply \[ 3/4 \] of the maximum moment at midspan. In other words, \[ M_A = M_C = 3/4 M_B \]. Therefore, the lateral-torsional buckling modification factor becomes:
\[ C_b = \frac{12.5 M_{\text{max}}}{2.5 M_{\text{max}} + 3M_A + 4M_B + 3M_C} = \frac{12.5(1.0)}{2.5(1.0) + 3(0.75) + 4(1.0) + 3(0.75)} = 1.14 \] \[ \text{[Eqn. F1-1]} \]

\[ L_p < L_b < L_r \] therefore the nominal moment in the lateral-torsional limit state is given by:
\[ M_n = C_b \left[ M_p - \left( M_p + 0.7F_yS_x\frac{L}{L_p} \right) \right] \leq M_p \]  
\[ M_n = 1.14 \left[ 900 - \left( 900 + 0.7(50)(14.9) \left( \frac{252 - 210}{580 - 210} \right) \right) \right] = 1,020 \text{ in} \cdot \text{k} = 85 \text{ ft} \cdot \text{k} \]

Flange buckling controls, \( M_n = 66.4 \text{ ft} \cdot \text{k} \)

LRFD

\( \phi_b M_n = 59.8 \text{ ft} \cdot \text{k} \)

ASD

\( M_n/\Omega_b = 39.8 \text{ ft} \cdot \text{k} \)

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
================================
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

*** DESIGN MESSAGES ***:
================================
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

CHECKS FOR TORSION
V. AISC 360-16 HSST Slender Flange F.8

Verify the available flexural strength of a square HSS flexural member with slender flange per AISC 360-16 code.

**References**

**Related Links**

- [D1.A.5.3 Flexural Design Strength](on page 1086)

**Details**

Verify the bending capacity of a HSST 18x8x3/16. The member is used as a 21 ft simple span subject to a uniform dead load of 0.125 kip/ft and a uniform live load of 0.375 kip/ft. The member is continuously braced. The material is ASTM A500 Grade C ($F_y = 50$ ksi).

**Validation**

Ultimate load (for LRFD):

$$w_u = 1.2(0.125) + 1.6(0.375) = 0.75 \text{ kip/ft}$$

$$M_u = w_u L^2/8 = (0.75)(21)^2/8 = 41.3 \text{ kip-ft}$$

Service level load (for ASD):

$$w_a = 0.125 + 0.375 = 0.50 \text{ kip/ft}$$

$$M_a = w_a L^2/8 = (0.50)(21)^2/8 = 27.6 \text{ kip-ft}$$

Flange slenderness ratio

$$\lambda = b/t_f = 43.0$$ (From Reference 1, Table 1-12)
\[ \lambda_r = 1.40\sqrt{\frac{E}{F_y}} = 1.40\sqrt{\frac{29,000}{50}} = 33.7 \]

\[ \lambda > \lambda_r \text{, therefore, the flange is slender.} \]

Web slenderness ratio:
\[ \lambda = \frac{h}{t_f} = 54.4 \text{ (From Reference 1, Table 1-12)} \]
\[ \lambda_p = 2.42\sqrt{\frac{E}{F_y}} = 2.42\sqrt{\frac{29,000}{50}} = 58.3 \]

\[ \lambda < \lambda_p \text{, therefore, the web is compact (limit state of web local buckling need not be checked).} \]

### Flange Local Buckling

\[ M_n = F_y S_e \quad \text{[Eqn. F7-3]} \]

Where

- \( S_e \) = the effective section modulus \( \frac{I_{eff}}{(H/2)} \)
- \( I_{eff} \) = the effective moment of inertia. A simplified method as presented in Reference 2 is used, with the effective flange width:

\[ I_{eff} \approx I_x - (\frac{\Sigma b_i^3}{12} + \Sigma a_d^2) \]

- \( b_e \) = the effective flange width of the compression flange, per Section F7.2(c) of Reference 1:

\[ b_e = 1.92 t_f \sqrt{\frac{E}{F_y}} \left(1 - \frac{0.38}{b_f t_f} \sqrt{\frac{E}{F_y}} \right) \leq b \]

- \( b \) = usable flange width

\[ b_e = 1.92(0.174)\sqrt{\frac{29,000}{50}} \left(1 - \frac{0.38}{0.174} \sqrt{\frac{29,000}{50}} \right) = 6.33 \text{ in} \]

The portion of the compression flange that is not effective: \( b - b_e = 7.48 - 6.33 = 1.15 \text{ in} \)

\[ I_{eff} = 54.4 - 2 \left[ \frac{1.15(0.174)^3}{12} + 1.15(0.174) \left( \frac{8.0 - 0.175}{2} \right)^2 \right] = 48.3 \text{ in}^4 \]

- \( S_e = \frac{48.3}{8.0/2} = 12.1 \text{ in}^3 \)

- \( M_n = 50 \times 12.1 = 605 \text{ in} \cdot \text{k} = 50.4 \text{ ft} \cdot \text{k} \)

**LRFD**

\[ \phi_b M_n = 45.4 \text{ ft} \cdot \text{k} \]

**ASD**

\[ \frac{M_n}{\Omega_b} = 30.2 \text{ ft} \cdot \text{k} \]

STAAD.Pro Output

STAAD.PRO CODE CHECKING - AISC 360-16 LRFD (V1.2)
************************************************************************************************
ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
================================
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.
AISC Spec. STAAD.Pro Description
------------ ----------- -------------------------------
X Pz FX Axial force.
Y Vy FY Shear force along minor axis.
Z Vx FZ Shear force along major axis.
           Tz MX Torsional moment.
            My MY Bending moment about minor axis.
              Mx MZ Bending moment about major axis.

*** DESIGN MESSAGES ***:
================================
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase
based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 I Minor Axis Bending F.5

Check the minor axis bending capacity of an I-shaped flexural member per the AISC 360-16 code.

References
2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017, pg F-28 – F-29, Example F.5

• D1.A.5.3 Flexural Design Strength (on page 1086)

Details
Verify the bending capacity of a W12x58 in bending about the weak axis. The member is used as a 15 ft simple span subject to a uniform dead load of 0.667 kip/ft and a uniform live load of 2.0 kip/ft. The member is braced at end points only. The material is ASTM A992 ($F_y = 50$ ksi).

Validation
Ultimate load (for LRFD):
\[ w_u = 1.2(0.667) + 1.6(2.0) = 4.0 \text{ kip/ft} \]
\[ M_u = w_u L^2/8 = (4.0)(15)^2/8 = 112.5 \text{ kip ft} \]

Service level load (for ASD):
\[ w_a = 0.667 + 2.0 = 2.67 \text{ kip/ft} \]
\[ M_a = w_a L^2/8 = (2.67)(15)^2/8 = 75.1 \text{ kip ft} \]
Per the User Note in F6.2, the W12x58 has compact flanges in minor axis bending. Therefore, flange local buckling does not control. **Yielding**

\[ M_p = F_yZ_y \leq 1.6F_yS_y \]  
\[ M_p = 50 \times 32.5 = 1,625 \text{ in} \cdot \text{k} = 135.4 \text{ ft} \cdot \text{k} \]
\[ 1.6 \times 50 \times 21.4 = 1,712 \text{ in} \cdot \text{k} = 142.7 \text{ ft} \cdot \text{k} \]
\[ M_p = 135.4 \text{ ft} \cdot \text{k} \]

**LRFD**
\[ \phi_b M_n = 121.9 \text{ ft} \cdot \text{k} \]

**ASD**
\[ M_n/\Omega_b = 81.2 \text{ ft} \cdot \text{k} \]

### Verification Examples

#### V.09 Steel Design

| Vy | FY | Shear force along minor axis. |
| Vx | FZ | Shear force along major axis. |
| Tz | MX | Torsional moment. |
| My | MY | Bending moment about minor axis. |
| Mx | MZ | Bending moment about major axis. |

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.

E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

Related Links
• D1.A.5.3 Flexural Design Strength (on page 1086)

Details
Verify the bending capacity of an 8" x-strong pipe. The member is used as a 16 ft simple span. The member is braced only at end points. The material is ASTM A53 Grade B ($F_y = 35$ ksi).

Validation
Slenderness ratio
\[
\lambda = \frac{D}{t} = 18.5 \quad \text{(From Reference 1, Table 1-14)}
\]
\[
\lambda_p = 0.07E/F_y = 0.07 \times \frac{29,000}{35} = 58
\]
\[
\lambda < \lambda_p \text{ therefore, the section is compact (limit state of flange local buckling need not be checked).}
\]
\[
\frac{0.45E}{F_y} = \frac{0.45 \times 29,000}{35} = 373 > 18.5
\]
Therefore, section F8.1 (Round HSS) of Reference 1 applies:
\[
M_n = M_p = F_y Z = 35 \times 31.0 = 1,085 \text{ in-k = 90.4 ft-k}
\]
LRFD
\[
\phi_b M_n = 81.38 \text{ ft-k}
\]
ASD
\[
\frac{M_n}{\Omega_b} = 54.14 \text{ ft-k}
\]
Results

STAAD.PRO CODE CHECKING - AISC 360-16 LRFD (V1.2)
******************************************************************************
ALL UNITS ARE - KIP  FEET (UNLESS OTHERWISE Noted).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
========================
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

*** DESIGN MESSAGES ***:
=======================
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along.
E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.
   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 W Flex Memb F.1-1A

Verify the available flexural strength of a continuously braced wide-flange member per the AISC 360-16 code.

References
2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017, pg F-8, Example F.1-1B

Related Links
• D1.A.5.3 Flexural Design Strength (on page 1086)

Details
Verify the bending capacity of a W18x50. The member is used as a 35 ft simple span. The member is continuously braced. The material is ASTM A992 ($F_y = 50$ ksi).

Validation
Per the User Note in F2, the W18x35 has compact flanges in major axis bending. Therefore, flange local buckling does not control. Further, as the member is continuously braced, lateral-torsional buckling does not control.

Yielding

\[
M_n = M_p = F_y Z_x = 50 \times 101 = 5,050 \text{ in k} = 420.8 \text{ ft k}
\]

LRFD

\[
\phi_b M_n = 378.8 \text{ ft k}
\]

ASD

\[
M_n / Q_b = 252.0 \text{ ft k}
\]

Results

V. AISC 360-16 W Flexural Check LRFD

Verify the flexural yielding strength and lateral torsional buckling of an I section using the LRFD method per AISC 360-16.
References

Related Links

• *D1.A.5.3 Flexural Design Strength* (on page 1086)

Details

Verify the flexural yielding strength and lateral torsional buckling of an I section (W12X90) gr. ASTM A992 material, with a member length of 41'-8", and a concentrated moment of 35,000 in-kip applied at midspan. The member is unbraced along its length.

Validation

Flexural yielding about X axis

As the section is compact, nominal flexural yielding strength about X axis is:

\[
M_{nx} = f_y \times Z_{xx} = 65 \text{ ksi} \times 311 \text{ in}^3 = 20,215 \text{ in} \cdot \text{kip}
\]

\[
M_x = \phi_c \times M_{nx} = 0.9(20,215 \text{ in} \cdot \text{kip}) = 18,193.5 \text{ in} \cdot \text{kip}
\]

(F2-1, ref. 1)

Flexural yielding about Y axis

As this is the minor axis, nominal flexural yielding strength about Y axis is:

\[
M_{ny} = f_y \times Z_{yy} = 65 \text{ ksi} \times 143 \text{ in}^3 = 9,295 \text{ in} \cdot \text{kip}
\]

\[
M_y = \phi_c \times M_{ny} = 0.9(9,295 \text{ in} \cdot \text{kip}) = 8,365.5 \text{ in} \cdot \text{kip}
\]

(F6-1, ref. 1)

Lateral torsional buckling about X axis

\[
r_y = \sqrt{\frac{I_{yy}}{A_g}} = 3.243\text{in}^2
\]

limiting laterally unbraced length for the yielding limit state:

\[
L_p = 1.76 \times r_y \sqrt{\frac{E}{F_y}} = 120.56\text{in}
\]

(F2-5, ref. 1)

\[
r_{ts} = \sqrt{\frac{J_{yy} \times C_w}{S_{xx}}} = 3.769\text{in}
\]

(F2-7, ref. 1)

For an I section, C = 1 (per F2-28a in ref. 1). The limiting unbraced length for the inelastic lateral-torsional buckling limit state is:

\[
h_0 = d - t_f = 12.66 \text{ in}
\]

\[
L_r = 1.95 \times r_{ts} \frac{E}{F_y} \sqrt{\frac{J_c}{S_{xx} h_0}} \left( \frac{J_c}{S_{xx} h_0} \right)^2 + 6.76 \left( \frac{0.7F_y}{E} \right)^2 = 810.27\text{in}
\]

L_p < L_b = 500 \text{ in} < L_r

\[
C_b = \frac{12.5M_{max}^2}{2.5M_A + 4M_B + 3M_c} = \frac{12.5(20,000)}{2.5(20,000) + 3(10,000) + 4(20,000) + 3(10,000)} = 1.316
\]

Nominal LTB strength:

\[
M_p = f_y \times Z_{xx} = 65 \text{ ksi} \times 311 \text{ in}^3 = 20,215 \text{ in} \cdot \text{kip}
\]
\[ M_n = C_b \left[ M_p - \left( M_p - 0.7F_y S_x \left( \frac{L_b - L_p}{L_r - L_p} \right) \right) \right] \leq M_p \]

\[ M_n = 20,611.4 \text{ in·kip} > M_p \]

\[ \phi_M_{nx} = 0.9(20,215 \text{ in·kip}) = 18,193.5 \text{ in·kip} \]

STAAD.PRO CODE CHECKING - AISC 360-16 LRFD (V1.2)
ALL UNITS ARE - KIP INCH (UNLESS OTHERWISE Noted).
V.AISC 360-16 W Local Buckling F.3A

Verify the available flexural local buckling capacity of a wide-flange section that is continuously braced with major axis bending per the AISC 360-16 code.

References
2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017, pg F-22 – F-23, Example F.3A

Related Links
• D1.A.5.3 Flexural Design Strength (on page 1086)

Details
Verify the bending capacity of a W21x48. The member is used as a 40 ft simple span. The member is continuously braced. The material is ASTM A992 ($F_y = 50$ ksi).

Validation
Flange Slenderness

\[
\lambda = \frac{b_t}{2t_f} = 9.47 \text{ (from Table 1-1 of Reference 1)}
\]

\[
\lambda_p = 0.38 \sqrt{\frac{E}{F_y}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15
\]

\[
\lambda_r = 1.0 \sqrt{\frac{E}{F_y}} = 1.0 \sqrt{\frac{29,000}{50}} = 24.1
\]

\[
\lambda_p < \lambda < \lambda_r \text{, therefore, the flange is non-compact.}
\]

Flange Local Buckling

\[
M_p = F_y Z_x = 50 \times 107 = 5,350 \text{ in} \cdot \text{k} = 445.8 \text{ ft} \cdot \text{k}
\]

For non-compact sections:

\[
M_n = M_p - \left(M_p - 0.7F_y S_x \left(\frac{\lambda - \lambda_p}{\lambda_r - \lambda_p}\right)\right) \leq M_p \quad \text{[Eqn. F3.1]}
\]

\[
M_n = 5,350 - \left[5,350 - 0.7(50)(93.0) \left(\frac{9.47 - 9.15}{24.1 - 9.15}\right)\right] = 5,303 \text{ in} \cdot \text{k} = 441.9 \text{ ft} \cdot \text{k}
\]

Since the member is continuously braced, lateral torsional buckling does not control.

LRFD
Verification Examples

V.09 Steel Design

\[ \phi_b M_n = 397.7 \text{ ft} \cdot \text{k} \]

ASD

\[ M_n / \Omega_b = 264.6 \text{ ft} \cdot \text{k} \]

*******************************************************************************

STAAD.Pro  4681  User Manual
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being \(\text{about}\) the relevant axis (X/Y), while the results for shear are reported as being for shear forces \(\text{along}\) the axis.
   E.g : \(\text{M}_x\) indicates bending about the X axis, while \(\text{V}_x\) indicates shear along the X axis.

V.AISC 360-16 W LTB Test F.1-2B
Verify the available lateral-torsional buckling capacity of a wide-flange section which is braced at third points with major axis bending per the AISC 360-16 code.

References
2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017, pg F-10 – F-11, Example F. 1-2B

Related Links
• D1.A.5.3 Flexural Design Strength (on page 1086)
**Details**

Verify the bending capacity of a W18x50. The member is used as a 35 ft simple span subject to uniform loads. The member is braced at ends and at third points. The material is ASTM A992 ($F_y = 50$ ksi).

**Validation**

**Nonuniform Moment Modification**

From Table 3-1 of Reference 1:

$C_b = 1.01$ for center segment

$C_b = 1.45$ for end segments

By inspection, the center segment will govern.

$L_b = \frac{35}{5} = 11.7$ ft

The limiting lengths for lateral-torsional buckling are:

$\frac{E}{F_y} \sqrt{\frac{J_c}{S_x h_o}} + \sqrt{\left(\frac{J_c}{S_x h_o}\right)^2 + 6.76 \left(\frac{E}{0.7 F_y}\right)^2}$

where

$c = 1$ for a doubly symmetric I-shape (Eqn. F2-8a)

$L_r = 1.95\sqrt{\frac{E}{F_y} \sqrt{\frac{J_c}{S_x h_o}} + \sqrt{\left(\frac{J_c}{S_x h_o}\right)^2 + 6.76 \left(\frac{E}{0.7 F_y}\right)^2}}$

$M_p = F_y Z_x = 50 \times 101 = 5,050$ in·k

$M_n = C_b \left[ M_p - \left( M_p - 0.7 F_y S_x \left( \frac{L_b - L_p}{L_r - L_p} \right) \right) \right] \leq M_p$

$M_n = 1.01 \left[ 5,050 - \left( 5,050 - 0.7(50)(88.9) \right) \left( \frac{11.7 - 5.83}{16.9 - 5.83} \right) \right] = 4,062$ in·k = 338.5 ft·k

**LRFD**

$\phi_b M_n = 304.7$ ft·k

**ASD**

$M_n / \Omega_b = 202.7$ ft·k

**Results**

*** DESIGN MESSAGES ***:
=======================
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear...

</tbody>
</table>

### Design Messages:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.
   - E.g: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 W Member Selection F.4

Verify the selection of an optimized wide flange section for major axis bending per the AISC 360-16 code.

References

Select a wide flange section based on moment of inertia required to limit deflection. The member is used as a 30 ft simple span which carries a uniform dead load of 0.8 kip/ft and a uniform live load of 2 kip/ft. The member is continuously braced. The material is ASTM A992 ($F_y = 50 \text{ ksi}$).

**Validation**

Ultimate load (for LRFD):

$$w_u = 1.2(0.8) + 1.6(2.0) = 4.16 \text{ kip/ft}$$
$$M_u = w_uL^2/8 = (4.16)(30)^2/8 = 468 \text{ kip-ft}$$

Service level load (for ASD):

$$w_a = 0.8 + 2.0 = 2.8 \text{ kip/ft}$$
$$M_a = w_aL^2/8 = (2.8)(30)^2/8 = 315 \text{ kip-ft}$$

**Minimum Moment of Inertia**

Assume a live load deflection limit of $L/360 = 30 \times 12/360 = 1.0 \text{ in}$

$$\Delta_{\text{max}} = \frac{5wL^4}{384EI}$$
$$I_{\text{min}} = \frac{5wL^4}{384EI_{\text{max}}} = \frac{5(2.0)(30)^4(12)^3}{384(29,000)(1.0)} = 1,260 \text{ in}^4$$

Try a W24x55 ($I_x = 1,350 \text{ in}^4$)

The W24x55 is a compact section and the member is continuously braced.

$$M_n = M_p = F_yZ_x = 50 \times 134 = 6,700 \text{ in} \cdot \text{k}$$

**LRFD**

$$\phi_nM_n = 502.5 \text{ ft} \cdot \text{k} > 468 \text{ ft} \cdot \text{k} \quad \text{(OK)}$$

**ASD**

$$M_u/\Omega_b = 334.3 \text{ ft} \cdot \text{k} > 315 \text{ ft} \cdot \text{k} \quad \text{(OK)}$$

**Results**

*** DESIGN MESSAGES ***:

**************************************************
ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE NOTED).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations and axes labels as defined in the AISC 360-16 code. The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16 design results are reported in AISC 360-16 code axis convention.
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.

2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.

3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.

   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** ABBREVIATIONS ***:

***DESIGN MESSAGES***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along.
the X axis.

E.g: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.

2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.

3. Bending results are reported as being υabout the relevant axis (X/Y), while the results for shear are reported as being for shear forces υalong the axis.

E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

**WARNING** SOME MEMBER SIZES HAVE CHANGED SINCE LAST ANALYSIS. IN THE POST PROCESSOR, MEMBER QUERIES WILL USE THE LAST ANALYSIS FORCES WITH THE UPDATED MEMBER SIZES. TO CORRECT THIS INCONSISTENCY, PLEASE DO ONE MORE ANALYSIS. FROM THE UPPER MENU, PRESS RESULTS, UPDATE PROPERTIES, THEN FILE SAVE; THEN ANALYZE AGAIN WITHOUT THE GROUP OR SELECT COMMANDS.
******************************************************************************

V. AISC 360-16 WT Shape F.10

Verify the available flexural strength of a WT (“split tee”) member per the AISC 60-16 code.

References

Related Links
• D1.A.5.3 Flexural Design Strength (on page 1086)

Details
Verify the bending capacity of a WTSx6. The member is used as a 6.0 ft simple span. The member is continuously braced. The material is ASTM A992 (F_y = 50 ksi).

Validation
The member is continuously braced, so lateral-torsional buckling does not control.

Yielding
\[ M_n = F_y Z_x \leq 1.6 M_y \] [Eqn. F9-2]

where
\[ M_y = 50 \times 1.22 = 61 \text{ in} \cdot \text{k} \]
\[ M_n = 50 \times 2.20 = 110 \text{ in} \cdot \text{k} > 1.6(61.0) = 97.6 \text{ in} \cdot \text{k} \]

Flange Local Buckling
\[ \lambda = \frac{b}{2t_f} = 9.43 \text{ (from Table 1-8 of Reference 1)} \]

\[ \lambda_p = 0.38 \sqrt{\frac{E}{F_y}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15 \]

\[ \lambda_p = 1.0 \sqrt{\frac{E}{F_y}} = 1.0 \sqrt{\frac{29,000}{50}} = 24.1 \]

\[ \lambda_p < \lambda < \lambda_r, \text{ therefore, the flange is non-compact.} \]

For non-compact sections:

\[ M_n = M_p - \left( M_p - 0.7 F_y S_x \right) \left( \frac{\lambda - \lambda_p}{\lambda_r - \lambda_p} \right) \leq 1.6 M_y \]  

\[ M_n = 110 - \left[ 110 - 0.7(50)(3.20) \right] \frac{9.43 - 9.15}{24.1 - 9.15} = 110 \text{ in} \cdot \text{k} > 96.7 \text{ in} \cdot \text{k} \]

\[ M_n = 97.6 \text{ in} \cdot \text{k} = 8.13 \text{ ft} \cdot \text{k} \]

LRFD

\[ \phi_b M_n = 7.32 \text{ ft} \cdot \text{k} \]

ASD

\[ M_n / \Omega_b = 4.87 \text{ ft} \cdot \text{k} \]

*** DESIGN MESSAGES ***:

### 1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.

### 2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.

### 3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.

E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 Built Up Column E.2

Verify the available compressive strength of a built-up column with a slender web per the AISC 360-16 code.

References

Details
From reference 2:

Verify that a built-up, ASTM A572 Grade 50 column with PL1 in.×8 in. flanges and a PL4 in.×15 in. web... is sufficient to carry a dead load of 70 kips and live load of 210 kips in axial compression. The column’s unbraced length is 15 ft and the ends are pinned in both axes.

ASTM A572 Grade 50: \( F_y = 50 \text{ ksi} \)

Validation
Refer to reference.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis. E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 | Compression LRFD
Verify the flexural buckling capacity of an I section under compressive load using the LRFD method per the AISC 360-16 code.
Verify the Flexural Buckling strength of an I Section (W14x90) using the LRFD method

Steel Gr. ASTM A992, about X and Y axis with a member length of 30 ft with dead load 140 kips and Live Load 420 kips.

**Validation**

Strong axis unbraced length, $L_x = 360 \text{ in}$

Torsional axis unbraced length $L_y = 180 \text{ in}$

Ultimate load, $P_u = 1.2(180 \text{ kips}) + 1.6(420 \text{ kips}) = 840 \text{ kips}$

Calculation for major axis (X axis)

From Table C-A-7.1 of ref. 1, $K = 1.0$ for a pinned-pinned condition.

$$\frac{b_f}{2t_f} = 10.211 < 0.56\sqrt[2]{\frac{E}{F_y}} = 13.487,$$ thus the flange is non-slender.

Slenderness ratio about X axis $= \frac{KL_x}{r_x} = 58.632 < 4.71\sqrt[2]{\frac{E}{F_y}} = 113.432$

Calculate the elastic critical buckling stress: $F_{eX} = \frac{\pi^2E}{(KL_x/r_x)^2} = 83.259\text{ksi}$

Calculate the flexural buckling stress: $F_{crX} = 0.658\frac{F_y}{F_{eX}}F_y = 38.887\text{ksi}$

Compressive strength for flexural buckling along X: $P_{FBX} = \phi_cF_{crX}A_g = 947.462\text{kips}$

Ratio for flexural buckling strength = 0.906

Calculation for minor axis (Y axis)

$$h = d - 2t_f = 12.58 \text{ in}$$

$$\frac{h}{t_w} = 28.591 < 35.884,$$ thus the flange is non-slender.

Slenderness ratio about Y axis $= \frac{KL_y}{r_y} = 48.703 < 4.71\sqrt[2]{\frac{E}{F_y}} = 113.432$

Calculate the elastic critical buckling stress: $F_{eY} = \frac{\pi^2E}{(KL_y/r_y)^2} = 120.668\text{ksi}$

Calculate the flexural buckling stress: $F_{crY} = 0.658\frac{F_y}{F_{eY}}F_y = 42.039\text{ksi}$

Compressive strength for flexural buckling along Y: $P_{FBY} = \phi_cF_{crY}A_g = 1, 002.625\text{kips}$
Ratio for flexural buckling strength = 0.838

**Results**

******************************************************************************
ALL UNITS ARE - KIP  FEET (UNLESS OTHERWISE Noted).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
========================
The capacity results and intermediate results in the report follow the
notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC
360:16
design results are reported in AISC 360-16 code axis convention.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis. E.g: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted).

- Member : 1 Contd.
V.AISC 360-16 Pipe E.11

Verify the available compressive strength of a pipe section per the AISC 360-16 code.

References

Related Links
• D1.A.5.2 Axial Compression (on page 1086)

Details
From reference 2:

Select an ASTM A53 Grade B Pipe compression member with a length of 30 ft to support a dead load of 35 kips and live load of 105 kips in axial compression. The column is pin-connected at the ends in both axes and braced at the midpoint in the y-y direction.

ASTM A572 Grade 50: \( F_y = 35 \text{ ksi} \)

Validation
Refer to reference.

*** DESIGN MESSAGES ***:
==================================
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loaddcase
based on the code clause in AISC 360-16 will not be shown in the report.

3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis. E.g: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 Rect HSS E.9

Verify the available compressive strength of a rectangular HSS member per the AISC 360-16 code.

References

Related Links

- D1A.5.2 Axial Compression (on page 1086)

Details

From reference 2:

Select an ASTM A500 Grade C rectangular HSS compression member, with a length of 20 ft, to support a dead load of 85 kips and live load of 255 kips in axial compression. The base is fixed and the top is pinned.

ASTM A500 Grade C: $F_y = 50$ ksi

Validation

Refer to reference.

STAAD.PRO CODE CHECKING - AISC 360-16 LRFD (V1.2)
******************************************************************************
ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
****************************************************************************
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC
360:16 design results are reported in AISC 360-16 code axis convention.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

### Verification Examples

V.09 Steel Design

STAAD.Pro

User Manual
**DESIGN MESSAGES:**

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being \(\text{about}\) the relevant axis (X/Y), while the results for shear are reported as being for shear forces \(\text{along}\) the axis.
   
   E.g : \(M_x\) indicates bending about the X axis, while \(V_x\) indicates shear along the X axis.

**ABBREVIATIONS:**

V.AISC 360-16 W E.1B

Verify the compressive strength of a wide flange section per the AISC 360-16 code.

References

Related Links

- [D1.A.5.2 Axial Compression](on page 1086)

Details

From reference 2:

Verify a W14x90 is adequate to carry the loading... The column is pinned top and bottom in both axes and braced at the midpoint about the y-y axis and torsionally. The column is verified for ... ASTM A913 Grade 65 material.

ASTM A572 Grade 65: \( F_y = 65 \text{ ksi} \)

Validation

Refer to reference.

***DESIGN MESSAGES***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y),
while the results for shear are reported as being for shear forces along the axis. E.g.: $M_x$ indicates bending about the X axis, while $V_x$ indicates shear along the X axis.

V. AISC 360-16 Shear Strong Axis

Verify the shear strength of an I section loaded in the strong axis using the LRFD and ASD methods per AISC 360-16.

References

2. Design Examples, Version 15.0, American Institute of Steel Construction, 2017. pp G-3 - G-4, Example G.1A

Related Links

- D1.A.5.4 Design for Shear (on page 1087)

Details

From the reference:

The shear capacity values are evaluated from AISC Manual Table 2-4 and then calculated.

Validation

Area of the web used for shear is:

\[ A_w = d t_w = 23.7 \times 0.430 = 10.2 \text{ in}^2 \]

The nominal shear strength is:

\[ V_n = 0.6 F_y A_w C_{v1} = 0.6 (50)(10.2)(1.0) = 306 \text{ kips} \]

LRFD

The shear strength is:

\[ \phi V_n = 1.00(306) = 306 \text{ kips} \]

The ultimate shear demand is:

\[ V_u = 1.2 (48) + 1.6 (145) = 289.6 \text{ kips} \]
The allowable shear is:

\[ V_{n}/\Omega_{v} = 306 / 1.5 = 204 \text{ kips} \]

The shear demand is:

\[ V_{a} = 48 + 145 = 193 \text{ kips} \]

**DESIGN MESSAGES**:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis. E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 Shear Weak Axis

Verify the shear strength of an I section loaded in the weak axis using the LRFD and ASD methods per AISC 360-16.

References

Related Links
• D1.A.5.4 Design for Shear (on page 1087)

Details
From the reference:
Verify the available shear strength and adequacy of an ASTM A992 W21X48 beam with end shears of 20.0 kips from dead load and 60.0 kips from live load in the weak direction.

**Validation**

\( C_{v2} = 1.0 \) for all ASTM A6 W shapes with \( F_y \leq 70 \) ksi, per the User Note in section G6 of the AISC 360-16 specification.

The nominal shear strength is:

\[
V_n = 2 \times [0.6F_y b_t t_f C_{v2}] = 2 \times [0.6 (50)(8.14)(0.43)(1.0)] = 210.0 \text{ kips}
\]

**LRFD**

The shear strength is:

\[
\phi_V V_n = 0.90(210.0) = 189.0 \text{ kips}
\]

The ultimate shear demand is:

\[
V_u = 1.2 (20) + 1.6 (60) = 120 \text{ kips}
\]

**ASD**

The allowable shear is:

\[
V_{n/\Omega} = 306 / 1.67 = 125.8 \text{ kips}
\]

The shear demand is:

\[
V_a = 20 + 60 = 80 \text{ kips}
\]

**Results**

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
=============
The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:

The capacity results and intermediate results in the report follow the notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16
design results are reported in AISC 360-16 code axis convention.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 Tapered I Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered I section member per both the LRFD and ASD methods of the AISC 360-16 code.

Details
A 5' × 5' portal frame consists of W12x72 columns and a steel tapered member for the beam.
The following load cases are evaluated:

1. A uniformly distributed load of -3.5 k/ft along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. Lateral loads at the top of the right column of -50 kips in the global X direction and 45 kips in the global Z direction (out of plane).
4. A concreted load of -100 kips in the global Y direction and a concentrated torque of 9 in-kips at mid-span of the beam.
Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ Fy = 50 \text{ ksi} \]

**Validation**

**Design Forces**

By inspection, the left end of the beam (shallowest overall depth) governs under the symmetric loads present. The following design loads are used from the STAAD.Pro analysis are then used:

1. \[ Mz = 32.26 \text{ in}\cdot\text{kips}, Fy = 8.755 \text{ kips} \]
2. \[ Mz = 677.6 \text{ in}\cdot\text{kips}, My = 2.942 \text{ in}\cdot\text{kips}, Mx = 5.106 \text{ in}\cdot\text{kips}, Fy = 22.49 \text{ kips}, Fx = 0.098 \text{ kips}, Fz = 5.473 \text{ kips} \]
3. \[ Mz = 275.9 \text{ in}\cdot\text{kips}, Mx = 4.497 \text{ in}\cdot\text{kips}, Fy = 50.23 \text{ kips}, Fx = 5.473 \text{ kips} \]
4. \[ Mz = 654.5 \text{ in}\cdot\text{kips}, My = 5.298 \text{ in}\cdot\text{kips}, Mx = 9.192 \text{ in}\cdot\text{kips}, Fy = 22.50 \text{ kips}, Fx = 0.177 \text{ kips}, Fz = 24.35 \text{ kips} \]

**Section Properties**

The section at the left end \((D = 18 \text{ in.})\) has the following properties:

- Web height, \(d_w = 18 - 2\times0.84 = 16.32 \text{ in.}\)
- Area, \(A_g = (0.84)(9 + 7.5) + 16.32 (0.36) = 19.74 \text{ in}^2\)
- Shear area in local \(y\), \(A_y = 16.32(0.36) = 5.875 \text{ in}^2\)
- Shear area in local \(x\), \(A_x = 0.84(9 + 7.5) = 13.86 \text{ in}^2\)
- Dist to centroid \(y\), \(c = \frac{7.5(0.84)(0.84)}{19.74} + 3.6\left(16.32\frac{0.84}{19.74} - \frac{0.84}{2} + 9\left(0.84\frac{18 - 0.84}{19.74}\right)\right) = 9.548 \text{ in.}\)
- Moment of inertia about major axis,
  \[ I_{zz} = \frac{7.5(0.84)^3}{12} + 7.5(0.84)(9.548 - \frac{0.84}{2})^2 \]
- Moment of inertia about minor axis,
  \[ I_{yy} = \frac{0.84(9)^3}{12} + 16.32(0.36)^3 + \frac{0.84(7.5)^3}{12} = 80.62 \text{ in}^4\]

Elastic section modulus about major axis top flange fiber, \(S_{xx,top} = \frac{I_{zz}}{D - c} = \frac{1.146}{18 - 9.548} = 135.5 \text{ in}^3\)

Elastic section modulus about major axis bottom flange fiber, \(S_{xx,bottom} = \frac{I_{zz}}{c} = \frac{1.146}{9.548} = 120.0 \text{ in}^3\)

Elastic section modulus about minor axis, \(S_{yy} = \frac{I_{yy}}{b_f^2} = \frac{80.62}{9.74^2} = 17.92 \text{ in}^3\)

Radius of gyration about major axis, \(r_x = \sqrt{\frac{I_{zz}}{A_g}} = \sqrt{\frac{1.147}{19.74}} = 7.619 \text{ in}\)

Radius of gyration about minor axis, \(r_y = \sqrt{\frac{I_{yy}}{A_g}} = \sqrt{\frac{80.62}{19.74}} = 2.021 \text{ in}\)
Location of the plastic neutral axis, \( y_{PNA} = 0.84 + \frac{19.74 - 2(7.5)(0.84)}{2 \times 0.36} = 10.75 \) in.

Plastic section modulus about major axis,
\[
Z_{zt} = \frac{7.5(10.75)^2}{2} \cdot \frac{(7.5 - 0.36)(10.75 - 0.84)^2}{2} + \frac{9(18 - 10.75)^2}{2} \cdot \frac{(9 - 0.36)(18 - 0.84 - 10.75)^2}{2} = 141.8 \text{ in}^3
\]

Plastic section modulus about minor axis, \( Z_y = \frac{0.84(9)^2}{4} + \frac{16.32(0.36)^2}{4} + \frac{0.84(7.5)^2}{4} = 29.35 \text{ in}^3 \)

Torsional constant, \( J = \frac{9(0.84)^3}{3} + \frac{16.32(0.36)^3}{3} + \frac{7.5(0.84)^3}{3} = 3.514 \text{ in}^4 \)

Section Classification

Flange in compression
\[
\lambda = \frac{b}{t} = \frac{1/2 \times 7.5}{0.84} = 4.464
\]
\[
k_c = \frac{4}{\sqrt{\frac{d_w}{t_w}}} = \frac{4}{\sqrt{\frac{16.32}{0.36}}} = 0.594
\]
Per Table B4.1a, \( \lambda < \lambda_r = 0.64 \sqrt{\frac{k_c E}{F_y}} = 0.64 \sqrt{\frac{0.594(29,000)}{50}} = 11.88 \), therefore flanges are non-slender for compression.

Web in compression
\[
\lambda = \frac{d_w}{t_w} = \frac{16.32}{0.36} = 45.33
\]
Per Table B4.1a, Case 5, \( \lambda > \lambda_r = 1.49 \sqrt{\frac{E}{F_y}} = 1.49 \sqrt{\frac{29,000}{50}} = 35.88 \), therefore the web is slender for compression.

Flange in bending (use half the longer flange width as the outstanding width):
\[
\lambda = \frac{b_f}{t_f} = \frac{9}{2(0.84)} = 5.36
\]
Per Table 1.b, Case 11, \( \lambda < \lambda_p = 0.38 \sqrt{\frac{E}{F_y}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15 \), therefore flange is compact for bending.

Web in bending
\[
\lambda = \frac{d_w}{t_w} = \frac{16.32}{0.36} = 45.33
\]
Per Table 1.b, Case 15, \( \lambda < \lambda_p = 3.76 \sqrt{\frac{E}{F_y}} = 3.76 \sqrt{\frac{29,000}{50}} = 90.55 \), therefore web is compact for bending.

Compression Capacity

About X Axis:
\[ \frac{k_x L_x}{r_x} = \frac{1.0(60)}{7.619} = 7.875 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

\[ F_{ex} = \frac{n^2 E}{(k_x L_x)^2} = \frac{n^2 \times 29,000}{(7.875)^2} = 4.615 \text{ ksi} \]  

(Eq. E3-4)

\[ F_y \cdot \frac{F_{ex}}{F_{ex}} = \frac{50}{4.615} = 0.011 < 2.25 \]

(Eq. E3-2)

\[ F_{crx} = 0.658 \left( \frac{F_{ex}}{F_y} \right) = 0.658(0.011)50 = 49.77 \text{ ksi} \]

Since the web is slender, use the effective area. The effective width imperfection adjustment factors (Table E7.1):

\[ c_1 = 0.18 \]

\[ c_2 = 1.31 \]

\[ F_{el} = \left( c_2 \frac{\lambda_y}{\lambda} \right)^2 F_y = \left( 1.31 \frac{35.88}{45.33} \right)^2 = 53.76 \text{ ksi} \]

(Eq. E7-5)

Therefore, the effective depth of the web in compression for the effective area:

\[ d_e = d_w \left( 1 - c_1 \frac{F_{el}}{F_{crx}} \right) = 16.32 \left( 1 - 0.18 \frac{53.76}{49.77} \right) = 13.78 \text{ in.} \]

(Eq. E7-3)

The reduced area of the section then becomes:

\[ A_e = 19.75 \cdot (16.32 \cdot 13.78)0.36 = 18.84 \text{ in.}^2 \]

\[ P_{nx} = A_e \times F_{crx} = 18.84 \times 49.77 = 937.4 \text{ kips} \]

(Eq. E7-1)

About Y Axis:

\[ \frac{k_y L_y}{r_y} = \frac{1.0(60)}{2.021} = 29.69 < 4.71 \sqrt{\frac{E}{F_y}} = 113.4 \]

\[ F_{ey} = \frac{n^2 E}{(k_y L_y)^2} = \frac{n^2 \times 29,000}{(29.69)^2} = 324.7 \text{ ksi} \]

(Eq. E3-4)

\[ F_y \cdot \frac{F_{ey}}{F_{ey}} = \frac{50}{324.7} = 0.154 < 2.25 \]

(Eq. E3-2)

\[ F_{cry} = 0.658 \left( \frac{F_y}{F_{ey}} \right) F_y = 0.658(0.154)50 = 46.88 \text{ ksi} \]

Therefore, the effective depth of the web in compression for the effective area:

\[ d_e = d_w \left( 1 - c_1 \frac{F_{el}}{F_{crx}} \right) = 16.32 \left( 1 - 0.18 \frac{53.76}{46.88} \right) = 14.11 \text{ in.} \]

(Eq. E7-3)

The reduced area of the section then becomes:

\[ A_e = 19.75 \cdot (16.32 \cdot 14.11)0.36 = 18.93 \text{ in.}^2 \]
\[ P_{ny} = A_e \times F_{cry} = 18.93 \times 46.88 = 887.4 \text{ kips} \]  
(Eq. E7-1)

The Y axis governs; \( P_n = P_{ny} \). The axial capacity:

- The ultimate compression capacity (LRFD) = \( \phi_p P_n = 0.9 \times 887.4 = 798.3 \text{ kips} \)
- The allowable compression capacity (ASD) = \( P_n / \Omega_c = 887.4 / 1.67 = 531.4 \text{ kips} \)

Calculate Bending Capacity

Bending capacity in plastic yielding about Y axis:

\[ M_y = F_y \times Z_y = 50 \times 29.35 = 1,468 \text{ in} \cdot \text{kips} > 1.6F_y \times S_y = 1.6 (50) (17.92) = 1,434 \text{ in} \cdot \text{kips} \]

Use \( M_y = 1,434 \text{ in} \cdot \text{kips} \)

The bending capacity for flexural yielding about the Y axis:

- The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 1,434 = 1,290 \text{ in} \cdot \text{kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,434 / 1.67 = 858.4 \text{ in} \cdot \text{kips} \)

Bending capacity in plastic yielding about X axis:

**Note:** In the critical load case (LC4), the bending at the left end is reverse (i.e., "hogging"). Thus, the bottom flange is in compression, which has a lower elastic section modulus.

Calculate the bending strength reduction factor:

\[ R_{pg} = 1 - \frac{a_w}{1,200 + 300 a_w} \left( \frac{h_c}{t_w} - 5.7 \sqrt{\frac{E}{F_y}} \right) \leq 1.0 \]  
(Eq. F5.6)

where

- \( h_c = 2 \times (9.548 - 0.84) = 17.42 \text{ in.} \)
- \( a_w = \frac{h_c t_w}{b_f c t_f} = \frac{17.42 \times 0.36}{7.5 \times 0.84} = 0.995 \)

\[ R_{pg} = 1 - \frac{0.995}{1,200 + 300(0.995)} \left( \frac{17.42}{0.36} - 5.7 \sqrt{\frac{29,000}{50}} \right) = 1.01; \text{ use } = 1.0 \]

\[ M_n = R_{pg} \times F_y \times S_{yc} = 1.0 \times 50 \times 120 = 6,000 \text{ in} \cdot \text{kips} \]

The bending capacity for flexural yielding about the X axis:

- The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 6,000 = 5,400 \text{ in} \cdot \text{kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 5,000 / 1.67 = 3,593 \text{ in} \cdot \text{kips} \)

Lateral-torsional buckling about the X axis:

\[ L_p = 1.1 r_t \sqrt{\frac{E}{F_y}} \]  
(Eq. F4-7)

where

- \( r_t = \) the effective radius of gyration for lateral-torsional buckling. For I-shapes with rectangular compression flanges:

\[ = \frac{b_c}{\sqrt{12(1 + \frac{1}{6} a_w)}} \]
Thus, \( r_t = \frac{7.5}{\sqrt{12(1 + \frac{1}{6}0.995)}} = 2.005 \) and \( L_p = 1.1 \left( \frac{29,000}{50} \right) = 53.12 \) in. Therefore, lateral-torsional buckling must be checked.

\[
L_r = 1.95 r_t \frac{E}{F_L} \sqrt{\frac{J}{S_{xc} h_o}} + \sqrt{\left( \frac{J}{S_{xc} h_o} \right)^2 + 6.76 \left( \frac{F_L}{E} \right)}
\]  
(Eq. F4-8)

where

\[
F_L = 0.7 F_y = 0.7 (50) = 35 \text{ ksi}
\]

\[
h_o = \text{distance between flange centroids} = 18 - 0.84 = 17.16 \text{ in.}
\]

\[
L_r = 1.95 \left( \frac{29,000}{35} \right) \frac{3.514}{120 \times 17.16} + \sqrt{\left( \frac{3.514}{120 \times 17.16} \right)^2 + 6.76 \left( \frac{35}{29,000} \right)^2} = 235.4 \text{ in.}
\]

As \( L_r < L_b = 60 < L_p \), the nominal moment capacity is:

\[
M_n = C_b R_p c M_{yc} \left( \frac{L_r - L_p}{L_b - L_p} \right) \leq R_p c M_{yc}
\]  
(Eq. F4-2)

where

\[
C_b = 1.0
\]

\[
M_{yc} = F_y S_{xc} = 50 \times 120 = 6,000 \text{ ksi}
\]

\[
M_p = F_y Z_x = 50 \times 141.8 = 7,090 \text{ ksi} \leq 1.6 F_y S_x = 9,600 \text{ ksi}
\]

\[
M_n = 1.0 \left( 1.182(6, 000) - \left[ 1.182(6, 000) - 35(120) \right] \left( \frac{60 - 53.12}{235.4 - 53.12} \right) \right) = 6,983 \text{ ksi}
\]

The bending capacity for lateral-torsional buckling:

The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 6,983 = 6,285 \text{ in·kips} \)

The allowable bending capacity (ASD) = \( M_y / \Omega_b = 6,983 / 1.67 = 4,181 \text{ in·kips} \)

**Compression Flange Yielding**

\[
M_n = R_{pc} \times M_{yc}
\]  
(Eq. F4-1)

where

\[
I_{yc} = \text{moment of inertia of the compression flange about the Y axis}
\]

\[
I_{yc} = \frac{0.84(7.5)^2}{12} = 29.53 \text{ in}^4
\]

\[
M_{yc} = M_y \times S_{xc} = M_y \times S_{xx, top} = 50 \times 135.5 = 6,775 \text{ in·kips}
\]

\[
R_{pc} = \text{the web plastification factor, } = \frac{M_p}{M_{yc}} = \frac{7,090}{6,775} = 1.046 \text{ when}
\]

\[
I_{yc} / I_y = \frac{29.53}{80.62} = 0.366 > 0.23 \text{ and}
\]

\[
h_c / t_w = \frac{17.42}{0.36} = 48.38 < \lambda_{pw} = 90.55 \text{ (limiting slenderness for a compact web per Table 1b case 15)(Eq. F4-9a)}
\]

\[
M_n = 1.046 \times 6,775 = 7,087 \text{ in·kips}
\]

The bending capacity for compression flange yielding:

The ultimate bending capacity (LRFD) = \( \phi_b M_n = 0.9 \times 7,087 = 6,378 \text{ in·kips} \)

The allowable bending capacity (ASD) = \( M_n / \Omega_b = 7,087 / 1.67 = 4,244 \text{ in·kips} \)
Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 2:

\[ \frac{P_r}{P_c} = \frac{24.7}{798.3} = 0.031 < 0.2 \text{ (LRFD)} \]

\[ \frac{P_r}{P_c} = \frac{24.7}{531.4} = 0.046 < 0.2 \text{ (ASD)} \]

So use Eq. H1-1b for both methods: \( \frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{ex}} + \frac{M_{ry}}{M_{ey}} \right) \leq 1.0 \).

\[ \frac{0.031}{2} + \left( \frac{677.6}{6,378} + \frac{2.942}{1,321} \right) = 0.124 \text{ (LRFD)} \]

\[ \frac{0.046}{2} + \left( \frac{677.6}{4,244} + \frac{2.942}{878.7} \right) = 0.188 \text{ (ASD)} \]

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/
3. Bending results are reported as being \textit{about} the relevant axis (X/Y), while the results for shear are reported as being \textit{for} shear forces \textit{along} the axis.

E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

***NOTE: AISC 360-16 Design Statement for STAAD.Pro.***

The capacity results and intermediate results in the report follow the notations and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC 360:16 design results are reported in AISC 360-16 code axis convention.
SECTION FORCES AXIS MAPPING:

*** DESIGN MESSAGES ***:
1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 Tapered Tube Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered tube section member per both the LRFD and ASD methods of the AISC 360-16 code.

Details

A 5’ × 5’ portal frame consists of W12x72 columns and a steel tapered member for the beam.

The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concreted torque of 0.75 in-kips at mid-span of the beam.

Material Properties
E = 29,000 ksi  
Fy = 50 ksi  

Validation

Design Forces

By inspection, the right end of the beam (shallowest overall depth) governs under the symmetric loads present. The following design loads are used from the STAAD.Pro analysis are then used:

\[ M_z = 505.66 \text{ in}\cdot\text{kips} \]
\[ F_y = 67.2 \text{ kips} \]
\[ F_x = 10.23 \text{ kips} \]

Section Properties

The section at the right end (OD = 10 in.) has the following properties:

Inner diameter, ID = 9 in.
Area, \( A_g = \pi/4(OD^2 - ID^2) = 14.92 \text{ in}^2 \)
Form factor = \( 0.49 + 0.8(t/OD) = 0.53 \)
Shear area, \( A_y = 14.92(0.53) = 7.909 \text{ in}^2 \)
Moment of inertia, \( I = \frac{\pi}{64}(OD^4 - ID^4) = 168.8 \text{ in}^4 \)
Elastic section modulus, \( S = \frac{\pi}{32} \left( \frac{OD^4 - ID^4}{OD} \right) = 33.76 \text{ in}^3 \)
Radius of gyration, \( r = \sqrt{\frac{I}{A_g}} = \sqrt{\frac{168.8}{14.92}} = 3.363 \text{ in} \)
Plastic section modulus, \( Z = \frac{OD^3 - ID^3}{6} = 45.17 \text{ in}^3 \)
HSS Torsional constant, \( C = \frac{\pi}{2}(OD-t)^2 t = 70.88 \text{ in}^3 \)

Section Classification

Flange in compression

\[ \lambda = \frac{OD}{t} = \frac{10}{0.5} = 20 \]

Per Table B4.1a, Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} \) = 63.8, therefore flanges are non-slender for compression. The web is similarly non-slender for compression.

Flange in bending (use half the longer flange width as the outstanding width):

\[ \lambda = \frac{OD}{t} = \frac{10}{0.5} = 20 \]

Per Table B4.1b, Case 20, \( \lambda < \lambda_r = 0.07 \frac{E}{F_y} \) = 40.6, therefore flange is compact for bending.

Compression Capacity

\[ \frac{kL}{r} = \frac{1.0(60)}{3.363} = 17.84 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]
The axial capacity:

The ultimate compression capacity (LRFD) = ϕcPn = 0.9 × 729.0 = 656.1 kips
The allowable compression capacity (ASD) = Pn/Ωc = 729.0 / 1.67 = 436.5 kips

Shear Capacity

The distance from the maximum shear force (ends) to zero shear force (mid-span), Lv = L / 2 = 30 in.

The critical shear stress, Fcr, is the minimum of:

Fcr1 = \frac{1.60E}{\sqrt{Lv OD}} = 633.4 ksi
Fcr2 = \frac{0.78E}{OD} = 252.9 ksi
Fcr3 = 0.6Fy = 30 ksi
Fcr = 30 ksi

Nominal shear capacity:

Vn = Fcr A_s/2 = 223.8 kips

The shear capacity:

The ultimate shear capacity (LRFD) = φcVn = 0.9 × 223.8 = 201.5 kips
The allowable shear capacity (ASD) = Vn/Ωc = 223.8 / 1.67 = 134.0 kips

Calculate Bending Capacity

Bending capacity in plastic yielding:

M_p = Fy × Z = 50 × 45.17 = 2,259 in·kips < 1.6Fy × S = 1.6 (50) (33.76) = 2,701 in·kips

The bending capacity for flexural yielding:

The ultimate bending capacity (LRFD) = ϕbMy = 0.9 × 2,259 = 2,033 in·kips
The allowable bending capacity (ASD) = My/Ωb = 2,259 / 1.67 = 1,352 in·kips

Torsional Capacity

The critical stress, Fcr, is the larger of:
\[ F_{cr1} = \frac{1.23E}{\sqrt{\frac{L}{OD} \left( \frac{OD}{t} \right)^4}} = 344.3 \text{ ksi} \]

\[ F_{cr2} = \frac{1.23E}{\left( \frac{OD}{t} \right)^2} = 194.5 \text{ ksi} \]

But shall not exceed:

\[ F_{cr3} = 0.6F_y = 30 \text{ ksi} \]

\[ F_{cr} = 30 \text{ ksi} \]

Nominal torsional capacity:

\[ T_n = F_{cr}C = 2,126 \text{ in·kips} \]

The torsional capacity:

- The ultimate torsional capacity (LRFD) = \( \phi c T_n = 0.9 \times 2,126 = 1,914 \text{ kips} \)
- The allowable torsional capacity (ASD) = \( T_n/\Omega_c = 2,126 / 1.67 = 1,273 \text{ kips} \)

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:

\[ \frac{P_r}{P_c} = \frac{10.23}{656.1} = 0.016 < 0.2 \text{ (LRFD)} \]

\[ \frac{P_r}{P_c} = \frac{10.23}{436.5} = 0.023 < 0.2 \text{ (ASD)} \]

So use Eq. H1-1b for both methods:

\[ \frac{P_r^2}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0. \]

\[ 0.016^2 + \left( \frac{505.7}{2033} + \frac{0}{2033} \right) = 0.257 \text{ (LRFD)} \]

\[ 0.023^2 + \left( \frac{505.7}{1352} + \frac{0}{1352} \right) = 0.386 \text{ (ASD)} \]

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y), while the results for shear are reported as being for shear forces ◆along◆ the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

*** DESIGN MESSAGES ***:
=======================
1. Section classification reported is for the cross section and loadcase that
produced the worst case design ratio for flexure/compression Capacity
results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase
based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y),
while
the results for shear are reported as being for shear forces ◆along◆
the axis.
E.g : Mx indicates bending about the X axis, while Vx indicates shear along
the X axis.

## V. AISC 360-16 UPT Pipe Section

Verify the axial compression capacity, shear capacity, flexure capacity, torsional capacity, and interaction ratio of a user-provided pipe section member per both the LRFD and ASD methods of the AISC 360-16 code.

### Details

A 5' × 5' portal frame consists of W12x72 columns and a UPT pipe member for the beam. The pipe outer diameter, $D$, is 10" and the thickness, $t$, is 0.25".
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concentrated torque of 0.75 in·kips at mid-span of the beam.

Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ F_y = 50 \text{ ksi} \]

Validation

Design Forces
The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 599.6 \text{ in-kips}, F_y = 67.5 \text{ kips} \)

**Section Properties**

Inner diameter, \( d = 10 - 2\times0.25 = 9.5 \text{ in.} \)

Area, \( A_g = \frac{\pi}{4}(D^2 - d^2) = 7.66 \text{ in}^2 \)

Shear area, \( A_y = A_x = A_g / 2 = 3.83 \text{ in}^2 \)

Moment of inertia, \( I_x = I_y = \frac{\pi}{64}(D^4 - d^4) = 91.05 \text{ in}^4 \)

Elastic section modulus, \( S_{xx} = \frac{I_x}{D/2} = \frac{91.05}{10/2} = 18.21 \text{ in}^3 \)

Radius of gyration, \( r_x = \sqrt{\frac{I_{xx}}{A_g}} = \sqrt{\frac{91.05}{7.66}} = 3.448 \text{ in} \)

Plastic section modulus, \( Z_x = \frac{1}{6}(D^3 - d^3) = 23.77 \text{ in}^3 \)

HSS Torsional constant, \( C = \frac{n}{2}(D - t)^2t = 37.33 \text{ in}^3 \)

**Section Classification**

Flange in compression

\[ \lambda = \frac{D}{t} = \frac{10}{0.25} = 40 \]

Per Table 4.1a Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} = 0.11 \frac{29,000}{50} = 63.8 \), therefore flanges are non-slender for compression.

Web in compression

Per Table 4.1a, Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} = 0.11 \frac{29,000}{50} = 63.8 \), therefore the web is non-slender for compression.

Flexure classification:

Per Table 4.1b, Case 20, \( \lambda < \lambda_p = 0.07 \frac{E}{F_y} = 0.07 \frac{29,000}{50} = 40.6 \), therefore flange is compact for bending.

**Compression Capacity**

Effective slenderness ratio:

\[ \frac{k_x L_x}{r_x} = \frac{1.060}{3.448} = 0.30 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 47.1 \]

Elastic buckling stress:

\[ F_e = \frac{n^2E}{\left(\frac{k_x L_x}{r_x}\right)^2} = \frac{50^2 \times 29,000}{(17.40)^2} = 945 \text{ ksi} \] (Eq. E3-4)

\[ \frac{F_y}{F_e} = \frac{50}{945} = 0.053 < 2.25 \]
Critical buckling stress:

\[
F_{cr} = 0.658 \left( \frac{F_y}{F_e} \right) = 0.658 \left( \frac{0.053}{50} \right) = 48.91 \text{ ksi}
\]  
(Eq. E3-2)

Nominal buckling strength:

\[
P_n = A_g \times F_{cr} = 7.66 \times 48.91 = 374.5 \text{ kips}
\]  
(Eq. E3-1)

The axial capacity:

- The ultimate compression capacity (LRFD) = \( \phi_c P_n = 0.9 \times 374.5 = 337.0 \text{ kips} \)
- The allowable compression capacity (ASD) = \( P_n / \Omega_c = 374.5 / 1.67 = 224.3 \text{ kips} \)

Calculate Shear Capacity

Critical stress is the minimum of \( F_{cr1}, F_{cr2}, \) and \( F_{cr3} \):

\[
F_{cr1} = \frac{1.23E}{\sqrt{\frac{I}{D}}} \left( \frac{D}{t} \right)^{3/4} = 144.8 \text{ ksi}
\]

\[
F_{cr2} = \frac{0.78E}{\left( \frac{D}{t} \right)^{3/2}} = 89.4 \text{ ksi}
\]

\[
F_{cr3} = 0.6F_y \times A_c = 30 \times 3.83 = 114.9 \text{ kips}
\]

So, \( F_{cr} = 30 \text{ ksi} \).

The nominal shear strength:

\[
V_n = F_{cr} \times A_c = 30 \times 3.83 = 114.9 \text{ kips}
\]

The axial capacity:

- The ultimate shear capacity (LRFD) = \( \phi_v V_n = 0.9 \times 114.9 = 103.4 \text{ kips} \)
- The allowable shear capacity (ASD) = \( V_n / \Omega_v = 114.9 / 1.67 = 68.78 \text{ kips} \)

Calculate Bending Capacity

Bending capacity in plastic yielding (compact section):

\[
M_y = F_y \times Z_x = 50 \times 23.77 = 1,189 \text{ in} \cdot \text{kips}
\]  
(Eq F8-1)

The bending capacity for flexural yielding about the Y axis:

- The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 1,189 = 1,070 \text{ in} \cdot \text{kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,189 / 1.67 = 711.7 \text{ in} \cdot \text{kips} \)

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:

\[
\frac{P_r}{P_c} = \frac{11.75}{337.0} = 0.034 < 0.2 \text{ (LRFD)}
\]

\[
\frac{P_r}{P_c} = \frac{11.75}{224.3} = 0.052 < 0.2 \text{ (ASD)}
\]
So use Eq. H1-1b for both methods: \( \frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0 \).

\[
\frac{0.034}{2} + \left( \frac{599.6}{1,070} + \frac{0}{1,070} \right) = 0.578 \text{ (LRFD)}
\]

\[
\frac{0.052}{2} + \left( \frac{599.6}{711.7} + \frac{0}{711.7} \right) = 0.869 \text{ (ASD)}
\]

**Calculate Torsion Capacity**

Critical stress is the minimum of \( F_{cr1}, F_{cr2}, \) and \( F_{cr3} \). From shear calculations, \( F_{cr} = 30 \text{ ksi} \).

The nominal shear strength:

\[ T_n = F_{cr} \times C = 30 \times 37.33 = 1,120 \text{ in·kips} \]

The axial capacity:

- The ultimate torsional capacity (LRFD) = \( \phi_T T_n = 0.9 \times 1,120 = 1,008 \text{ in·kips} \)
- The allowable torsional capacity (ASD) = \( T_n / \Omega_T = 114.9 / 1.67 = 670.6 \text{ in·kips} \)

**STAAD.Pro Input**

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\AISC 360-16 UPT Pipe Section.STD` is typically installed with the program.

The following [D1.A.6 Design Parameters](on page 1093) are used:

- The welded pipe member is specified using STP 2
- Shear lag factor, $U$ for tension rupture capacity is specified by SLF 0.8

The remaining parameters all use their default values.

STAAD.PRO CODE CHECKING - AISC 360-16 LRFD (V1.2)
******************************************************
ALL UNITS ARE - KIP  INCH (UNLESS OTHERWISE Noted).
***NOTE : AISC 360-16 Design Statement for STAAD.Pro.
*** AXIS CONVENTION ***:
=====================================
The capacity results and intermediate results in the report follow the
notations
and axes labels as defined in the AISC 360-16 code.
The analysis results are reported in STAAD.Pro axis convention and the AISC
360:16
design results are reported in AISC 360-16 code axis convention.

Mx               MZ         Bending moment about major axis.

*** DESIGN MESSAGES ***:
=======================
1. Section classification reported is for the cross section and loadcase
   that
   produced the worst case design ratio for flexure/compression Capacity
   results.
2. Results for any Capacity/Check that is not relevant for a section/
   loadcase
   based on the code clause in AISC 360-16 will not be shown in the
   report.
3. Bending results are reported as being \about\ the relevant axis (X/Y),
   while
   the results for shear are reported as being for shear forces \along\
   the axis.
   E.g : Mx indicates bending about the X axis, while Vx indicates shear
   along
   the X axis.

Intermediate Results:

Axial Capacity : $P_c = 224.25$ kip Cl.H1.1

Moment Capacity : $M_{cx} = 711.68$ kip-in Cl.H1.1

Moment Capacity : $M_{cy} = 711.68$ kip-in Cl.H1.1

---
### V. AISC 360-16 UPT Square Hollow Section

Verify the axial compression capacity, shear capacity, flexure capacity, torsional capacity, and interaction ratio of a user-provided hollow square section member per both the LRFD and ASD methods of the AISC 360-16 code.

#### Details

A 5' × 5' portal frame consists of W12x72 columns and a UPT SHS member for the beam. The section outer depth, D, is 8" and the thickness, t, is 0.30".

---

### Verification Examples

The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concentrated torque of 0.75 in-kips at mid-span of the beam.

Material Properties

- $E = 29,000$ ksi
- $F_y = 50$ ksi

Validation

Design Forces
The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 599.6 \text{ in-kips}, F_y = 67.5 \text{ kips} \)

Section Properties

- Inner depth, \( d = 8 - 2 \times 0.30 = 7.40 \text{ in.} \)
- Area, \( A_g = D^2 - d^2 = 9.24 \text{ in}^2 \)
- Shear area, \( A_w = 2 \times D \times t_w = 4.80 \text{ in}^2 \)
- Moment of inertia, \( I = \frac{1}{12} (D^4 - d^4) = 91.45 \text{ in}^4 \)
- Elastic section modulus, \( S = \frac{I}{D/2} = \frac{91.45}{8/2} = 22.86 \text{ in}^3 \)
- Radius of gyration, \( r = \sqrt{\frac{I}{A_g}} = \sqrt{\frac{91.45}{9.24}} = 3.146 \text{ in} \)
- Plastic section modulus, \( Z = \frac{1}{E} (D^3 - d^3) = 26.69 \text{ in}^3 \)
- HSS Torsional constant, \( C = 2 \left( B - t_w \right) \left( D - t_w \right) t_w^3 = 35.47 \text{ in}^3 \)

Section Classification

The design thickness, \( t = 0.93 \times t_w = 0.279 \text{ in} \)

The design depth, \( d = D - 3t = 7.163 \text{ in} \)

Flange in compression

\[ \lambda = \frac{d}{t} = \frac{7.163}{0.279} = 25.67 \]

Per Table 4.1a Case 6, \( \lambda < \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{50}} = 33.72 \), therefore flanges are non-slender for compression. Similar for the web of the square section.

Flexure classification of flange:

Per Table 4.1b, Case 17, \( \lambda < \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{50}} = 26.97 \), therefore flange is compact for bending.

Flexure classification of web:

Per Table 4.1b, Case 19, \( \lambda < \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{50}} = 58.28 \), therefore web is compact for bending.

Compression Capacity

Effective slenderness ratio:

\[ \frac{k_x L_x}{r_x} = \frac{1.0(60)}{3.146} = 19.07 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

Elastic buckling stress:

\[ F_e = \frac{n^2 E}{\left( \frac{k_x L_x}{r_x} \right)^2} = \frac{n^2 \times 29,000}{(19.07)^2} = 787 \text{ ksi} \]  
  (Eq. E3-4)
F_y = \frac{50}{787} = 0.064 < 2.25

Critical buckling stress:
\[ F_{cr} = 0.658 \left( \frac{F_y}{F_e} \right) = 0.658 \left( 0.064 \right) 50 = 48.68 \text{ ksi} \]

Nominal buckling strength:
\[ P_n = A_g \times F_{cr} = 9.24 \times 48.68 = 449.9 \text{ kips} \] (Eq. E3-1)

The axial capacity:

The ultimate compression capacity (LRFD) = \( \phi P_n = 0.9 \times 449.9 = 404.9 \text{ kips} \)
The allowable compression capacity (ASD) = \( P_n / \Omega_c = 449.9 / 1.67 = 269.4 \text{ kips} \)

**Calculate Shear Capacity**

The nominal shear strength:
\[ V_n = 0.6 \times F_y \times A_w \times C_{v2} \] (Eq. G4-1)

where
\[ C_{v2} = 1.0 \] per Section G2.2 with \( h/t = 25.67 \) and \( K_v = 5 \).

\[ V_n = 0.6 \times 50 \times 4.80 \times 1.0 = 144 \text{ kips} \]

The shear capacity:

The ultimate shear capacity (LRFD) = \( \phi_v V_n = 0.9 \times 144 = 129.6 \text{ kips} \)
The allowable shear capacity (ASD) = \( V_n / \Omega_v = 144 / 1.67 = 86.23 \text{ kips} \)

**Calculate Bending Capacity**

Bending capacity in plastic yielding (compact section):
\[ M_p = F_y \times Z_x = 50 \times 26.69 = 1,335 \text{ in·kips} \] (Eq F7-1)

The bending capacity for flexural yielding about the Y axis:

The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 1,335 = 1,201 \text{ in·kips} \)
The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,335 / 1.67 = 799.2 \text{ in·kips} \)

**Torsional Capacity**
\[ \frac{h}{t} = 25.67 < 2.45 \sqrt{\frac{F_c}{F_y}} = 59.0 \]

\[ F_{cr} = 0.6F_y = 30 \text{ ksi} \]

Nominal torsional capacity:
\[ T_n = F_{cr} \times C = 1,064 \text{ ksi} \]

The torsional capacity:

The ultimate torsional capacity (LRFD) = \( \phi_T T_n = 0.9 \times 1,064 = 957.7 \text{ kips} \)
The allowable torsional capacity (ASD) = \( T_n / \Omega_T = 1,064 / 1.67 = 637.2 \text{ kips} \)

**Interaction Ratio for Bending and Compression**

Check the interaction ratio for Load Case 1:
\[
\frac{P_r}{P_c} = \frac{11.80}{404.9} = 0.029 < 0.2 \text{ (LRFD)}
\]

\[
\frac{P_r}{P_c} = \frac{11.80}{269.4} = 0.044 < 0.2 \text{ (ASD)}
\]

So use Eq. H1-1b for both methods: \[\frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0.\]

\[
\frac{0.029}{2} + \left( \frac{599.7}{1,201} + \frac{0}{1,201} \right) = 0.514 \text{ (LRFD)}
\]

\[
\frac{0.044}{2} + \left( \frac{599.7}{799.2} + \frac{0}{799.2} \right) = 0.765 \text{ (ASD)}
\]

**Results**

The file C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\AISC 360-16 UPT Square Hollow Section.STD is typically installed with the program.

The following [D1.A.6 Design Parameters](page 1093) are used:

- The welded SHS member is specified using STP 2
- Shear lag factor, $U$ for tension rupture capacity is specified by SLF 0.8

The remaining parameters all use their default values.

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis. E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V. AISC 360-16 C Tension ASD

Verify the tensile yield and tensile rupture strength of channel section with ASD method for AISC 360-16 code.

Details

The member is a C5x9 section. Steel grade is ASTM A992. Member is loaded with dead load of 15 kips and live load of 50 kips. The member is welded (i.e., no bolt holes) and the shear lag factor, \( U \), is calculated as 0.908.

Validation

Service load: \( P = DL + LL = 65 \) kips

Tensile Yielding

Nominal tensile yield strength:

\[
P_{nY} = F_y A_g = 50 \times 2.64 = 132 \text{ kip} \tag{Eqn. D2-1}
\]

\[
P_{nY/\Omega_{nY}} = 132 / 1.67 = 79.04 \text{ kip}
\]

Ratio for tensile yield = 65 / 79.04 = 0.822

Tensile Rupture

Net area, \( A_n = A_g = 2.64 \text{ in}^2 \)

Effective net area based on D3: \( A_e = A_n \times U = 2.397 \text{ in}^2 \)

Nominal tensile rupture strength:

\[
P_{nR} = F_u A_e = 65 \times 2.397 = 155.8 \text{ kip} \tag{Eqn. D2-2}
\]

\[
P_{nR/\Omega_{nR}} = 155.8 / 2.00 = 77.9 \text{ kip}
\]

Ratio for tensile yield = 65 / 77.9 = 0.834
## Results

*** DESIGN MESSAGES ***:
**************************
1. Section classification reported is for the cross section and loadcase that
produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase
based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while
the results for shear are reported as being for shear forces along the axis.
E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

V.AISC 360-16 C Tension LRFD

Verify the tensile yield and tensile rupture strength of channel section with LRFD method for AISC 360-16 code.

Details

The member is a C5x9 section. Steel grade is ASTM A992. Member is loaded with dead load of 15 kips and live load of 50 kips. The member is welded (i.e., no bolt holes) and the shear lag factor, \( U \), is calculated as 0.908.

Validation

Ultimate load: \( P_u = 1.2 \times DL + 1.6 \times LL = 98 \) kips

Tensile Yielding

Nominal tensile yield strength:

\[
P_{nY} = F_y A_g = 50 \times 2.64 = 132 \text{ kip}
\]

\[
\phi_{tY} P_{nY} = 0.9 \times 132 = 118.8 \text{ kip}
\]

Ratio for tensile yield = 98 / 118.8 = 0.825

Tensile Rupture

Net area, \( A_n = A_g = 2.64 \text{ in}^2 \)

Effective net area based on D3: \( A_e = A_n \times U = 2.397 \text{ in}^2 \)

Nominal tensile rupture strength:

\[
P_{nR} = F_u A_e = 65 \times 2.397 = 155.8 \text{ kip}
\]

\[
\phi_{tR} P_{nR} = 0.75 \times 155.8 = 116.9 \text{ kip}
\]

Ratio for tensile yield = 98 / 116.9 = 0.839

Results

46. PERFORM ANALYSIS
** ALL CASES BEING MADE ACTIVE BEFORE RE-ANALYSIS. **
Verification Examples
V.09 Steel Design

- *D1.A.5.1 Axial Tension* (on page 1085)

**V. AISC 360-16 I Tension LRFD**
To verify the tensile yield strength of an I section using the LRFD method from the AISC 360-16 code.

**Reference**

**Related Links**
- *D1.A.5.1 Axial Tension* (on page 1085)

**Details**
Verify the tensile yield and tensile rupture strength of an I section (W8X21) using the LRFD method. The material is A992 ($F_y = 50$ ksi, $F_u = 65$ ksi)
The area of the bolt holes is assumed to be zero. A known shear lag factor of 0.908 is directly specified.
The length of the member is 25 ft. It is loaded axial in tension with a dead load of 30 kips and a live load of 90 kips.

**Validation**
The factored axial load, $P_u = 1.2 \times 30 + 1.6 \times 90 = 180$ kips

**Tensile Yield Strength**
The tensile yield strength: $\phi_{ty}P_{nY} = \phi_{ty} \times F_y \times A_g = 0.9 \times 50 \times 6.16 = 277.2$ kips
Ratio for yield strength: 0.649

**Tensile Rupture Strength**
For this example, $A_n$ is assumed equal to $A_g$.
Effective area, $A_e = A_n \times U = 6.16 \times 0.908 = 5.593$ in$^2$
The tensile rupture strength = $\phi_{tr}P_{nR} = \phi_{tr} \times F_u \times A_e = 0.75 \times 65 \times 5.593 = 272.672$ kips
Ratio for rupture strength: 0.660

**Results**

*** DESIGN MESSAGES ***:
=====================================================================
1. Section classification reported is for the cross section and loadcase
that produced the worst case design ratio for flexure/compression Capacity
results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase
based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being ◆about◆ the relevant axis (X/Y),
while
the results for shear are reported as being for shear forces ◆along◆
the axis.
E.g : Mx indicates bending about the X axis, while Vx indicates shear
along the X axis.

53. FINISH

V.AISC 360-16 L Tension ASD

Verify the tensile yield and tensile rupture strength of an angle section with ASD method for AISC 360-16 code.
Details
The member is an L4x4x1/2 section. Steel grade is ASTM A36. The member is axially loaded with dead load of 20 kips and a live load of 60 kips. The member is connected using bolts in 3/4”Ø holes. The shear lag factor, \( U \), is calculated as 0.869.

Validation
Service load: \( P = DL + LL = 80 \) kips

Tensile Yielding
Nominal tensile yield strength:
\[
P_{nY} = F_y A_g = 36 \times 3.75 = 135 \text{ kip} \quad \text{[Eqn. D2-1]}
\]
\[
P_{nY}/\Omega_{tY} = 132 / 1.67 = 80.83 \text{ kip}
\]
Ratio for tensile yield = 80 / 80.83 = 0.99

Tensile Rupture
Bolt hole area = \( \pi(0.75/2)^2 \) = 0.44 in\(^2\)
Net area, \( A_n = A_g - A_{bolthole} = 3.75 - 0.44 = 3.31 \) in\(^2\)
Effective net area based on D3: \( A_e = A_n \times U = 2.875 \) in\(^2\)
Nominal tensile rupture strength:
\[
P_{nR} = F_u A_e = 58 \times 2.875 = 166.7 \text{ kip} \quad \text{[Eqn. D2-2]}
\]
\[
P_{nR}/\Omega_{tR} = 166.7 / 2.00 = 83.37 \text{ kip}
\]
Ratio for tensile yield = 80 / 83.4 = 0.96

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being \about\ the relevant axis (X/Y), while the results for shear are reported as being for shear forces \along\ the axis.
   
   E.g : Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

### V. AISC 360-16 L Tension LRFD

Verify the tensile yield and tensile rupture strength of an angle section with LRFD method for AISC 360-16 code.

#### Details

The member is an L4x4x1/2 section. Steel grade is ASTM A36. The member is axially loaded with dead load of 20 kips and a live load of 60 kips. The member is connected using bolts in 3/4" holes. The shear lag factor, $U$, is calculated as 0.869.

#### Validation

**Ultimate load:** $P_u = 1.2 \times DL + 1.6 \times LL = 120$ kips

**Tensile Yielding**

Nominal tensile yield strength:

$$P_{ny} = F_y A_g = 36 \times 3.75 = 135 \text{ kip}$$

[Eqn. D2-1]
\[ \phi_{tY} P_{nY} = 0.9 \times 135 = 121.5 \text{ kip} \]

Ratio for tensile yield = 120 / 121.5 = 0.988

**Tensile Rupture**

Bolt hole area = \( \pi (0.75/2)^2 \) = 0.44 in\(^2\)

Net area, \( A_n = A_g - A_{bolthole} \) = 3.75 - 0.44 = 3.31 in\(^2\)

Effective net area based on D3: \( A_e = A_n \times U = 2.875 \text{ in}^2 \)

Nominal tensile rupture strength:

\[ P_{nR} = F_u A_e = 58 \times 2.875 = 166.7 \text{ kip} \]

\[ \phi_{tR} P_{nR} = 0.75 \times 166.7 = 125.1 \text{ kip} \]

Ratio for tensile yield = 80 / 83.4 = 0.960

**Results**

V. AISC 360-16 - Torsion

Verify the torsional strength of an angle section using the LRFD method in the AISC 360-16 code. Use the simple method for calculating torsional shears (i.e., no full twist analysis). Perform torsion checks per AISC Design Guide 9.
Reference

2. Torsional Analysis of Structural Steel Members Design Guide 9, American Institute of Steel Construction

Related Links

- D1.A.5.6 Design for Torsion (on page 1089)

Details

The angle section is an L 3x3x1/2 angle of ASTM A992 material. The member is a 2 ft long cantilever with a total end torque of 3.0 in-kips.

Validation

Maximum torsional shear stress: \( \tau_f = \frac{T}{J} = 3.0 \times \frac{0.5}{0.234} = 6.41 \text{ ksi} \)

By observation, direct shear stress is zero (torsion loading only). Therefore, total torsional stress is \( \tau_f \).

Torsional shear resistance: \( \phi_T \times 0.6 \times F_y = 0.9 \times 0.6 \times 50 = 27 \text{ ksi} \)

Ratio: \( \frac{6.41 \text{ ksi}}{27 \text{ ksi}} = 0.237 \)

Results

*** DESIGN MESSAGES ***:

1. Section classification reported is for the cross section and loadcase that produced the worst case design ratio for flexure/compression Capacity results.
2. Results for any Capacity/Check that is not relevant for a section/loadcase based on the code clause in AISC 360-16 will not be shown in the report.
3. Bending results are reported as being about the relevant axis (X/Y), while the results for shear are reported as being for shear forces along the axis.
   E.g.: Mx indicates bending about the X axis, while Vx indicates shear along the X axis.

**V. AISC 360-10 W Flex Memb F.1-1**

Verify the major axis flexural strength of a wide flange section which is continuously braced per the LRFD and ASD methods of the AISC 360-10 code.
Verification Examples
V.09 Steel Design

References

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Details**

From reference (2):

Select an ASTM A992 W-shape beam with a simple span of 35 ft. Limit the member to a maximum nominal depth of 18 in. Limit the live load deflection to L/360. The nominal loads are a uniform dead load of 0.45 kip/ft and a uniform live load of 0.75 kip/ft. Assume the beam is continuously braced.

See example F.1-1A and F.1-1B in reference (2) for calculations.

V. AISC 360-10 W LTB Test F.1-2

Verify the lateral-torsional buckling flexural strength of a wide flange section that is braced at the third points per the LRFD and ASD methods of the AISC 360-10 code.

References

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Details**

From reference (2):

Verify the available flexural strength of the W18×50, ASTM A992 beam selected in Example F.1-1A with the beam braced at the ends and third points.

See example F.1-2A and F.1-2B in reference (2) for calculations.

V. AISC 360-10 W LTB Test F.1-3B

Reference

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf
Problem

From reference (2):

Verify the available flexural strength of the W18×50, ASTM A992 beam selected in Example F.1-1A with the beam braced at the ends and center point.

See example F.1-3B in reference (2) for calculations.

### CHECK FOR BENDING-LATERAL TORSIONAL BUCKLING
V. AISC 360-10 C Flex Mem F.2-1

Verify the major axis flexural strength of a compact channel section which is continuously braced per the LRFD and ASD methods for AISC 360-10 code.

References

Details

From reference (2):

Select an ASTM A36 channel to serve as a roof edge beam with a simple span of 25 ft. Limit the live load deflection to L/360. The nominal loads are a uniform dead load of 0.23 kip/ft and a uniform live load of 0.69 kip/ft. The beam is continuously braced.

Validation

Ultimate moment:

\[ w_u = 1.2(0.23 \text{ kip/ft}) + 1.6(0.69 \text{ kip/ft}) = 1.38 \text{ kip/ft} \]

\[ M_{u} = \frac{1.38(25)^2}{8} = 108 \text{ ft-k} \]

Service moment:
$w_a = 0.23 \text{ k/ft} + 0.69 \text{ k/ft} = 0.92 \text{ k/ft}$

$M_a = \frac{0.92(25)^2}{8} = 71.9 \text{ ft-k}$

Try a C15×33.9, which has a plastic section modulus, $Z_x = 50.8 \text{ in}^2$.

All ASTM A36 grade C-shapes are compact. The member is continuously braced, so therefore the yielding limit state governs.

$M_n = M_p = F_y \times Z_x = 36 \times 50.8 = 1,830 \text{ in-k} = 152 \text{ ft-k}$

The available flexural strength:

LRFD: $\phi_b M_n = 0.90(152) = 137 \text{ ft-k}$

ASD: $M_n / \Omega_b = \frac{152}{1.67} = 91.0 \text{ ft-k}$

### V. AISC 360-10 C LTB Test F.2-2

Verify the lateral flexural strength of a compact channel section braced at the fifth points per the LRFD and ASD methods of the AISC 360-10 code.

**Reference**

**Problem**

Check a C15x33.9 channel of ASTM A36 steel which serves as a roof edge beam. The simple span is 25 ft. The nominal loads on the member are a dead load 0.23 kip/ft and a uniform live load of 0.69 kip/ft. The beam is braced at fifth points and at ends.

**Validation**

Ultimate moment:
\[ w_u = 1.2(0.23 \text{ k/ft}) + 1.6(0.69 \text{ k/ft}) = 1.38 \text{ k/ft} \]

\[ M_u = \frac{1.38(25)^2}{8} = 108 \text{ ft-k} \]

Service moment:
\[ w_a = 0.23 \text{ k/ft} + 0.69 \text{ k/ft} = 0.92 \text{ k/ft} \]

\[ M_a = \frac{0.92(25)^2}{8} = 71.9 \text{ ft-k} \]

The unbraced length, \( > L_b = 5 \text{ ft} \).

Try a C15\times33.9, which has a plastic section modulus, \( Z_x = 50.8 \text{ in}^2 \).

The lateral-torsional buckling modification factor, \( C_b = 1.0 \) for the center span of this bracing & loading condition.

\[ L_p = 1.76r\sqrt[12]{\frac{E}{F_y}} = 1.76(0.901)\sqrt[12]{\frac{29,000}{36}(\frac{1}{12})} = 3.75\text{ft} \quad (F2-5) \]

\[ L_r = \pi r t s \sqrt[12]{\frac{E}{0.7F_y}} = \pi(1.13)\sqrt[12]{\frac{29,000}{0.7 \times 36}(\frac{1}{12})} = 10.0 \text{ ft} \quad (F2-6) \]

**Note:** This is the simplified, conservative calculation for \( L_r \) per the User Note used to verify that the section is in the plastic-elastic range. The reference uses the more exact calculation but the resulting flexural strength values are essentially equal.

\[ L_p < L_b \leq L_r \]

All ASTM A36 grade C-shapes are compact.

The nominal flexural strength for the flexural yielding limit state is:

\[ M_n = M_p = F_y \times Z_x = 36 \times 50.8 = 1,830 \text{ in-k} = 152 \text{ ft-k} \]

The nominal flexural strength for the lateral-torsional buckling limit state is:

\[ M_n = C_b \left[ M_p - (M_p - 0.7F_y S_x) \left( \frac{L_b - L_p}{L_r - L_p} \right) \right] = 1.0\left[ 1, 830 - (1, 830 - 0.7 \times 36 \times 42) \left( \frac{5 - 3.75}{10 - 3.75} \right) \right] \left( \frac{1}{12} \right) = 145 \text{ ft-k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(145) = 131 \text{ ft-k} \)

ASD: \( M_n / \Omega_b = \frac{131}{1.67} = 86.8 \text{ ft-k} \)

**CHECK FOR BENDING-LATERAL TORSIONAL BUCKLING**
### V. AISC 360-10 W Local Buckling F.3

Verify the leg local buckling flexural strength of a non-compact wide flange section per the LRFD and ASD methods of the AISC 360-10 code.

**References**

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

**Details**

From reference (2):

Select an ASTM A992 W-shape beam with a simple span of 40 ft. The nominal loads are a uniform dead load of 0.05 kip/ft and two equal 18 kip concentrated live loads acting at the third points of the beam. The beam is continuously braced.

See example F.3A and F.3B in reference (2) for calculations.

Select an ASTM A992 W-shape flexural member by the moment of inertia, to limit the live load deflection to 1 in. The span length is 30 ft. The loads are a uniform dead load of 0.80 kip/ft and a uniform live load of 2 kip/ft. The beam is continuously braced.

See example F.4 in reference (2) for calculations.

V. AISC 360-10 I Minor Axis Bending F.5

Verify the minor axis bending capacity of an I-shaped flexural member under minor axis bending per the AISC 360-10 code.

References

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Details

From reference (2):

Select an ASTM A992 W-shape beam loaded in its minor axis with a simple span of 15 ft. The loads are a total uniform dead load of 0.667 kip/ft and a uniform live load of 2 kip/ft. Limit the live load deflection to L/240. The beam is braced at the ends only.

See example F.5 in reference (2) for calculations.

V. AISC 360-10 HSST Compact Flange F.6

Verify the available flexural strength of a square HSS flexural member with compact flanges per the AISC 360-10 code.
**Verification Examples**

**V.09 Steel Design**

**References**

**Details**

From reference (2):

Select a square ASTM A500 Grade B HSS beam to span 7.5 ft. The loads are a uniform dead load of 0.145 kip/ft and a uniform live load of 0.435 kip/ft. Limit the live load deflection to L/240. The beam is continuously braced.

**Validation**

Ultimate moment:

\[ w_u = 1.2(0.145 \text{ kip/ft}) + 1.6(0.435 \text{ kip/ft}) = 0.87 \text{ kip/ft} \]
\[ M_u = \frac{0.87(7.5)^2}{8} = 6.12 \text{ ft} \cdot \text{k} \]

Service moment:

\[ w_a = 0.145 \text{ kip/ft} + 0.435 \text{ kip/ft} = 0.580 \text{ kip/ft} \]
\[ M_a = \frac{0.58(7.5)^2}{8} = 4.08 \text{ ft} \cdot \text{k} \]

Try a HSS 3 1/2×3 1/2×1/8, which has a plastic section modulus, \( Z_x = 1.93 \text{ in}^3 \).

The yield strength, \( F_y = 46 \text{ ksi} \)

Flange compactness: \( \lambda = b/t = 27.2 \)

Determine the compact flange ratio limit from Table B4.1b: \( \lambda_p = 1.12 \sqrt{\frac{F_y}{29,000}} = 1.12 \sqrt{\frac{46}{29,000}} = 28.1 > \lambda \) (Compact)

\[ M_n = M_p = F_y \times Z_x = 46 \times 1.93 = 88.8 \text{ in} \cdot \text{k} = 7.40 \text{ ft} \cdot \text{k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(7.40) = 6.66 \text{ ft} \cdot \text{k} \)

ASD: \( M_n / \Omega_b = 7.40 / 1.67 = 4.43 \text{ ft} \cdot \text{k} \)

**Results**

<table>
<thead>
<tr>
<th>Result Type</th>
<th>Reference</th>
<th>STAAD.Pro</th>
<th>Difference</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \phi_b M_n ) (ft·k) [LRFD]</td>
<td>6.66*</td>
<td>6.66</td>
<td>none</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>$M_n/\Omega_b$ (ft·k) [ASD]</td>
<td>4.43*</td>
<td>4.43</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

*The reference gives $\phi_b M_n = 6.67$ ft·k and $M_n/\Omega_b = 4.44$, respectively. The differences are due to either rounding differences.*

V. AISC 360-10 HSST NonCompact Flange F.7

Verify the available flexural strength of a square HSS flexural member with non-compact flanges per the AISC 360-10 code.

References

Details

From reference (2):

Select a rectangular ASTM A500 Grade B HSS beam with a span of 21 ft. The loads include a uniform dead load of 0.15 kip/ft and a uniform live load of 0.4 kip/ft. Limit the live load deflection to L/240. The beam is braced at the end points only.

Validation

Ultimate moment:

\[ w_u = 1.2(0.15 \text{ kip/ft}) + 1.6(0.4 \text{ kip/ft}) = 0.82 \text{ kip/ft} \]

\[ M_u = \frac{0.82(21)^2}{8} = 45.2 \text{ ft-k} \]

Service moment:

\[ w_a = 0.15 \text{ kip/ft} + 0.4 \text{ kip/ft} = 0.55 \text{ kip/ft} \]

\[ M_a = \frac{0.55(21)^2}{8} = 30.3 \text{ ft-k} \]

Try a HSS 10×6×3/16, which has a plastic section modulus, \( Z_x = 18.0 \text{ in}^3 \) and a section modulus, \( S_x = 14.9 \text{ in}^3 \).

Flange compactness: \( \lambda = \frac{b}{t} = 31.5 \)

Determine the compact and slender flange ratio limits from Table B4.1b:
\[ \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{46}} = 28.1 \]

\[ \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{46}} = 35.2 \]

Thus, the section has a non-compact flange.

Web compactness: \( \lambda = \frac{h}{t} = 54.5 \)

\[ \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{46}} = 60.8 > \lambda \]

Thus, the section has a compact web.

\[ M_p = F_y \times Z_x = 46 \times 18.0 = 828 \text{ in-k} = 69.0 \text{ ft\cdot k} \]

\[ M_n = M_p - (M_p - F_y S) \left( 3.57 \frac{b}{F_y} \cdot 4.0 \right) \]

\[ = 828 - (828 - 0.7 \times 46 \times 14.9) \left( 3.57 \times 31.5 \sqrt{\frac{46}{29,000}} \cdot 4.0 \right) = 760 \text{ in-k} = 63.3 \text{ ft\cdot k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(63.3) = 57.0 \text{ ft\cdot k} \)

ASD: \( M_n \bigg/ \Omega_b = \frac{63.3}{1.67} = 37.9 \text{ ft\cdot k} \)

V. AISC 360-10 HSST Slender Flange F.8

Verify the available flexural strength of a square HSS flexural member with slender flanges per the AISC 360-10 code.

References

Details
From reference (2):

Verify the strength of an ASTM A500 Grade B HSS8×8×x with a span of 21 ft. The loads are a dead load of 0.125 kip/ft and a live load of 0.375 kip/ft. Limit the live load deflection to L/240. The beam is continuously braced.

Validation
Ultimate moment:

\[ w_u = 1.2(0.125 \text{ k/ft}) + 1.6(0.375 \text{ k/ft}) = 0.75 \text{ k/ft} \]

\[ M_u = \frac{0.75(21)^2}{8} = 41.3 \text{ ft·k} \]

Service moment:

\[ w_a = 0.125 \text{ k/ft} + 0.375 \text{ k/ft} = 0.50 \text{ k/ft} \]

\[ M_a = \frac{0.5(21)^2}{8} = 27.6 \text{ ft·k} \]

Try a HSS 8×8×3/16, which has a plastic section modulus, \( Z_x = 15.7 \text{ in}^3 \) and a section modulus, \( S_x = 13.6 \text{ in}^3 \).

The yield strength, \( F_y = 46 \text{ ksi} \)

Flange compactness: \( \lambda = b/t = 43.0 \)

Determine the slender flange ratio limit from Table B4.1b:

\[ \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{46}} = 35.2 < \lambda \text{ (Slender)} \]

Web compactness: \( \lambda = h/t = 43.0 \)

\[ \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{46}} = 60.8 > \lambda \]

Thus, the section has a compact web.

\[ M_n = F_y \times S_e \]  \( \text{(F7-3)} \)

where

\[ S_e = \text{the effective section modulus determined with the effective compression flange taken as } b_e \]
The width of the compression flange between the corners (assumed to be 1.5t) is:

\[ b = 8 - 2 \times 1.5 \times t = 8 - 3(0.174) = 7.48 \text{ in} > 6.53 \text{ in} \]

Thus, the ineffective width of the compression flange is: \( b - b_e = 7.48 - 6.53 = 0.95 \text{ in} \)

Subtract this contribution of this ineffective flange area from the gross moment of inertia to approximate the effective moment of inertia:

\[ I_{\text{eff}} \approx 54.4 - 2 \left[ \frac{0.95(0.174)^3}{12} + 0.95(0.174)(3.91)^3 \right] = 49.3 \text{ in}^4 \]

\[ S_e = \frac{I_{\text{eff}}}{d/2} = \frac{49.3}{8.0/2} = 12.3 \text{ in}^3 \]

\[ M_n = 46 \times 12.3 = 566 \text{ in-k} = 47.2 \text{ ft-k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(47.2) = 42.5 \text{ ft-k} \)

ASD: \( M_n / \Omega_b = \frac{47.2}{1.67} = 28.3 \text{ ft-k} \)

**Verification Examples**

*STAAD.Pro* User Manual 5096
V. AISC 360-10 Pipe F.9
Verify the available flexural strength of a compact pipe member per the AISC 360-10 code.

References

Details
From reference (2):
Select an ASTM A53 Grade B Pipe shape with an 8-in. nominal depth and a simple span of 16 ft. The loads are a total uniform dead load of 0.32 kip/ft and a uniform live load of 0.96 kip/ft. There is no deflection limit for this beam. The beam is braced only at the ends.

Validation
Ultimate moment:
\[ w_u = 1.2(0.32 \text{ k/ft}) + 1.6(0.96 \text{ k/ft}) = 1.92 \text{ k/ft} \]
\[ M_u = \frac{1.92(16)^2}{8} = 61.4 \text{ ft} \cdot \text{k} \]

Service moment:
\[ w_a = 0.32 \text{ k/ft} + 0.96 \text{ k/ft} = 1.28 \text{ k/ft} \]
\[ M_a = \frac{1.28(16)^2}{8} = 41.0 \text{ ft} \cdot \text{k} \]

Try a pipe 8 x-strong, which has a plastic section modulus, \( Z_x = 31.0 \text{ in}^3 \).

The yield strength, \( F_y = 35 \text{ ksi} \)

Compactness ratio: \( \lambda = D/t = 18.5 \)

Determine the slender flange ratio limit from Table B4.1b:
\[ \lambda_p = \frac{0.07E}{F_y} = \frac{0.07(29,000)}{35} = 58.0 > \lambda \text{ (Compact)} \]

By observation, \( \lambda < \frac{0.45E}{F_y} \), so Section F8 applies.

\[ \lambda_p = 2.42\sqrt{\frac{E}{F_y}} = 2.42\sqrt{\frac{29,000}{46}} = 60.8 > \lambda \]

\[ M_n = M_p = F_y \times Z_x = 35 \times 31.0 = 1,090 \text{ in} \cdot \text{k} = 90.4 \text{ ft} \cdot \text{k} \] \hspace{1cm} (F8-1)

The available flexural strength:
\[ LRFD: \phi_b M_n = 0.90(90.4) = 81.4 \text{ ft} \cdot \text{k} \]
ASD: \( M_n / \Omega_b = \frac{90.4}{1.67} = 54.1 \text{ ft-k} \)

V. AISC 360-10 WT Shape F.10

Verify the available flexural strength of a WT section per the LRFD and ASD methods of the AISC 360-10 code.

References

Details

From reference (2):

Select an ASTM A992 WT beam with a 5-in. nominal depth and a simple span of 6 ft. The toe of the stem of the WT is in tension. The loads are a uniform dead load of 0.08 kip/ft and a uniform live load of 0.24 kip/ft. There is no deflection limit for this member. The beam is continuously braced.

Validation

Ultimate moment:

\[ w_u = 1.2(0.08 \text{ k/ft}) + 1.6(0.24 \text{ k/ft}) = 0.48 \text{ k/ft} \]

\[ M_u = \frac{0.48(0.5)^2}{8} = 2.16 \text{ ft-k} \]

Service moment:

\[ w_a = 0.08 \text{ k/ft} + 0.24 \text{ k/ft} = 0.32 \text{ k/ft} \]
Try a WT5×6, which has a plastic section modulus, \(Z_x = 2.20 \text{ in}^3\) and a section modulus, \(S_x = 1.22 \text{ in}^3\).

### Flexural Yielding

\[
M_n = M_p = F_y \times Z_x = 50 \times 2.20 = 110 \text{ in} \cdot \text{k} < 1.6F_yS_x = 1.6 \times 50 \times 1.22 = 97.6 \text{ in} \cdot \text{k} \quad (F9-2)
\]

Lateral-torsional buckling does not govern since the member is continuously braced.

### Flange compactness

\[
\lambda = \frac{b_f}{2t_f} = 9.43
\]

Determine the compact and slender flange ratio limits from Table B4.1b:

\[
\lambda_{pf} = 0.38\sqrt{\frac{E}{F_y}} = 0.38\sqrt{\frac{29,000}{46}} = 9.15
\]

\[
\lambda_{rf} = 1.0\sqrt{\frac{E}{F_y}} = 1.0\sqrt{\frac{29,000}{46}} = 24.1
\]

Thus, the section has a non-compact flange.

\[
M_n = \left[ M_p - (M_p - 0.7F_yS_{xc})\left(\frac{\lambda - \lambda_{pf}}{\lambda_{rf} - \lambda_{pf}}\right)\right] = 110 - (110 - 0.7 \times 50 \times 3.20)\left(\frac{9.43 - 9.15}{24.1 - 9.15}\right) = 110 \text{ in} \cdot \text{k} > 1.6
\]

So use \(M_n = 97.6 \text{ in} \cdot \text{k} = 8.13 \text{ ft} \cdot \text{k}\)

The available flexural strength:

**LRFD:** \(\phi_b M_n = 0.90(8.13) = 7.32 \text{ ft} \cdot \text{k}\)

**ASD:** \(M_n / \Omega_b = \frac{8.13}{1.67} = 4.87 \text{ ft} \cdot \text{k}\)

V. AISC 360-10 Angle F.11A

Verify the available flexural strength of a single angle member per the AISC 360-10 code.

References

Details

From reference (2):

Select an ASTM A36 single angle with a simple span of 6 ft. The vertical leg of the single angle is up and the toe is in compression. The vertical loads are a uniform dead load of 0.05 kip/ft and a uniform live load of 0.15 kip/ft. There are no horizontal loads. There is no deflection limit for this angle. The angle is braced at the end points only. Assume bending about the geometric x-x axis and that there is no lateral-torsional restraint.

Note: The angle section is given a beta angle as the geometrical axis and principal axis are different. In STAAD.Pro the calculation is done with reference with the principal axis, but in AISC 360-10 Code geometrical axis is used calculating the capacities of the section.

Validation

Ultimate moment:

\[ w_u = 1.2(0.05 \text{ k/ft}) + 1.6(0.15 \text{ k/ft}) = 0.30 \text{ k/ft} \]

\[ M_u = \frac{0.30(6)^2}{8} = 1.35 \text{ ft·k} \]
Service moment:

\[ w_a = 0.05 \text{ k/ft} + 0.15 \text{ k/ft} = 0.20 \text{ k/ft} \]

\[ M_a = \frac{0.2(6)^2}{8} = 0.90 \text{ ft-k} \]

Try an L4×4×1/4, which has a section modulus, \( S_x = 1.03 \text{ in}^3 \).

The yield strength, \( F_y = 36 \text{ ksi} \)

The nominal flexural strength for the flexural yielding limit state:

\[ M_n = 1.5M_y = 1.5F_yS_x = 1.5 \times 36 \times 1.03 = 55.6 \text{ in-k} \quad (F10-1) \]

The yield moment for a single angle bent about its geometric axis with no lateral-torsional restraint:

\[ M_y = 0.8F_yS_x = 0.8 \times 36 \times 1.03 = 29.7 \text{ in-k} \]

Determine \( M_e \):

\[ M_e = \frac{0.66E b^4 c_b}{L b^2} \left[ 1 + 0.78 \left( \frac{L b^2}{b^2} \right)^2 - 1 \right] \]

where

\[ C_b = 1.14 \text{ from Ref. 1, Table 3-1} \]

\[ M_e = \frac{0.66(29,000)(4.0)^4(1/4)1.14}{(6 \times 12)^2} \left[ 1 + 0.78 \left( \frac{6 	imes 12(1/4)}{(4.0)^2} \right)^2 - 1 \right] = 110 \text{ in-k} > M_y \]

\[ M_n = \left( 1.92 - 1.17 \frac{M_y}{M_e} \right) M_y \leq 1.5M_y \]

\[ M_n = \left( 1.92 - 1.17 \frac{29.7}{110} \right) 29.7 = 39.0 \text{ in-k} \leq 1.5(29.7) = 44.6 \text{ in-k} \]

Leg local buckling

Leg slenderness ratio: \( \lambda = \frac{b}{t} = \frac{4.0}{1/4} = 16.0 \)

Determine the compact and slender leg ratio limits from Table B4.1b:

\[ \lambda_p = 0.54 \sqrt{\frac{E}{F_y}} = 0.54 \sqrt{\frac{29,000}{36}} = 15.3 \]

\[ \lambda_r = 0.91 \sqrt{\frac{E}{F_y}} = 0.91 \sqrt{\frac{29,000}{36}} = 25.8 \]

\( \lambda_p < \lambda < \lambda_r \); thus, the leg is non-compact in flexure.

\[ M_n = F_yS_c \left[ 2.43 - 1.72 \left( \frac{b}{t} \right) \sqrt{\frac{F_y}{E}} \right] \quad (F10-3) \]

where

\[ S_c = 0.80S_x = 0.80 \times 1.03 = 0.824 \text{ in}^3 \]

\[ M_n = 36 \times 0.824 \left[ 2.43 - 1.72(16.0) \sqrt{\frac{36}{29,000}} \right] = 43.3 \text{ in-k} \]

The lateral-torsional buckling limit state governs.
\[ M_n = 43.3 \text{ in} \cdot k = 3.25 \text{ ft} \cdot k \]

The available flexural strength:

**LRFD:** \( \phi_b M_n = 0.90(3.25) = 2.93 \text{ ft} \cdot k \)

**ASD:** \( \frac{M_n}{\Omega_b} = \frac{3.25}{1.67} = 1.95 \text{ ft} \cdot k \)

Verification Examples

V. AISC 360-10 W E.1C

Verify the compressive strength of an unbraced wide-flange section column about the Y-Y axis per the LRFD and ASD methods of the AISC 360-10 code.

---

Details

From the reference example E.1C:

Calculate the available strength of a W14×132 column with unbraced lengths of 30 ft in both axes.

From the reference example E.1A:

... an ASTM A992 (Fy = 50 ksi) W-shape column to carry an axial dead load of 140 kips and live load of 420 kips. The column is 30 ft long and is pinned top and bottom in both axes.

See example E.1C in reference (2) for calculations.

Details

From the reference example E.1C

Calculate the available strength of a W14×90 with a strong axis unbraced length of 30.0 ft and weak axis and torsional unbraced lengths of 15.0 ft.

From the reference example E.1A:

... an ASTM A992 (Fy = 50 ksi) W-shape column to carry an axial dead load of 140 kips and live load of 420 kips. The column is 30 ft long and is pinned top and bottom in both axes.

See example E.1D in reference (2) for calculations.

#### CHECK FOR BENDING-LATERAL TORSIONAL BUCKLING

---

**STAAD.Pro** 5130 **User Manual**
### V. AISC 360-10 - E-2

**Reference**

**Related Links**

- [D1.A.5.2 Axial Compression](#) (on page 1086)

**Problem**

From the reference:

> Verify that a built-up, ASTM A572 Grade 50 column with PL 1 in. × 8 in. flanges and a PL 4 in. × 15 in. web is sufficient to carry a dead load of 70 kips and live load of 2.10 kips in axial compression. The column length is 15 ft and the ends are pinned in both axes.
Validation

Ultimate load:

\[ P_u = 1.2(70 \text{ kips}) + 1.6(210 \text{ kips}) = 420 \text{ kips} \]

Service load:

\[ P_a = 70 \text{ kips} + 210 \text{ kips} = 280 \text{ kips} \]

Section Properties

Built-up section properties (ignoring fillet welds):

\[ A = 2(8.0)(1.0) + 15.0(0.25) = 19.8 \text{ in}^2 \]

\[ I_x = \sum A d^2 + \sum b h^3 = 2 \left[ 8(8.0)^2 + \frac{8.0(1.0)^3}{12} \right] + \frac{0.25(15.0)^3}{12} = 1,100 \text{ in}^4 \]

\[ I_y = \frac{8.0^3}{12} + \frac{15.0 \times 0.25^3}{12} = 85.4 \text{ in}^4 \]

\[ r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{85.4}{19.8}} = 2.08 \text{ in} \]

Elastic Flexural Buckling Stress

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

\[ \frac{K L r_y}{r_y} = \frac{1.0(15.0)(2.08)}{2.08} = 86.5 \]

\[ F_e = \frac{n^2 E}{(K L / r_y)^2} = \frac{n^2(29,000)}{(86.5)^2} = 38.3 \text{ ksi} \]  

(Eq. E3-4)

Slenderness

Check for slender flanges and then determine the unstiffened element (flange) reduction factor.

\[ k_c = \frac{4}{\sqrt{h/t_w}} = \frac{4}{\sqrt{15.0/0.25}} = 0.516 \]  

(Table B4.1b note a)

\[ 0.35 < k_c < 0.76 \]

Flange slenderness:

\[ \lambda = \frac{b}{t} = \frac{4.0}{1.0} = 4.0 \]

The limiting flange slenderness ratio, \( \lambda_r \):

\[ \lambda_r = 0.64 \sqrt{\frac{k_c E}{F_y}} = 0.64 \sqrt{\frac{0.516(29,000)}{50}} = 11.1 > \lambda \]  

(Table B4.1a, case 2)

Thus, the flanges are not slender and there is no reduction (\( Q_s = 1.0 \)).

Check for slender web and then determine the stiffened element (web) reduction factor.

Web slenderness:

\[ \lambda = \frac{h}{t} = \frac{15.0}{0.25} = 60.0 \]
The limiting web slenderness ratio, $\lambda_r$:

$$\lambda_r = 1.49\sqrt{\frac{E}{F_y}} = 1.49\sqrt{\frac{29,000}{50}} = 35.9 < \lambda$$

(Table B4.1a, case 5)

Thus, the web is slender.

$$Q_a = \frac{A_e}{A_g}$$

(Eq. E7-16)

where

- $A_e = \text{the effective area based on the reduced effective width, } b_e$
- $b_e = 1.92t\sqrt{\frac{E}{F_y}}\left[1 - \frac{0.34}{(b/t)}\sqrt{\frac{E}{F_y}}\right] \leq b$ (Eq. E7-17)
- $f = F_{cr}$ calculated based on $Q = 1.0$
- $F_{cr} = Q\left(0.658\frac{QF_y}{F_e}\right)F_y = 1.0\left[0.658\frac{1.0(50)}{38.3}\right]50 = 29.0 \text{ ksi because}$

$$\frac{KL}{r} = 86.5 < 4.71\sqrt{\frac{E}{QF_y}} = 4.71\sqrt{\frac{29,000}{1.0(50)}} = 113$$

$$b_e = 1.92(0.25)\sqrt{\frac{29,000}{29.0}}\left[1 - \frac{0.34}{(15/0.25)}\sqrt{\frac{29,000}{29.0}}\right] = 12.5 \text{ in} < 15 \text{ in}$$

$$A_e = b_e t_w + 2b_f t_f = 12.5(0.25) + 2(8.0)(1.0) = 19.1 \text{ in}^2$$

$$Q_a = \frac{19.1}{19.8} = 0.965$$

$$Q = Q_s Q_a = 1.0 \times 0.965 = 0.965$$

$$\frac{KL}{r} = 86.5 < 4.71\sqrt{\frac{E}{QF_y}} = 4.71\sqrt{\frac{29,000}{0.965(50)}} = 115$$

$$F_{cr} = Q\left(0.658\frac{QF_y}{F_e}\right)F_y = 0.965\left[0.658\frac{0.965(50)}{38.3}\right]50 = 28.5 \text{ ksi}$$

Nominal Compressive Strength

$$P_n = F_{cr} A_g = 28.5(19.8) = 564 \text{ kips}$$

(Eq E7-1)

The available compressive strength:

LRFD: $\phi_c P_n = 0.90(564) = 508 \text{ kips}$

ASD: $P_n / \Omega_c = \frac{564}{1.67} = 338 \text{ kips}$

### CHECK FOR BENDING-LATERAL TORSIONAL BUCKLING
V. AISC 360-10 Built up I E.3

Verify the compressive strength of a built-up I section with slender flanges per the LRFD and ASD methods of the AISC 360-10 code.

References

Related Links

- [D1.A.5.2 Axial Compression](#) (on page 1086)

Details

From reference (2):

Determine if a built-up, ASTM A572 Grade 50 column with PL3/8 in. × 102 in. flanges and a PL1/4 in. × 74 in. web has sufficient available strength to carry a dead load of 40 kips and a live load of 120 kips in axial compression. The column's unbraced length is 15.0 ft in both axes and the ends are pinned.

Validation

Ultimate load:
\[ P_u = 1.2(40 \text{ kips}) + 1.6(120 \text{ kips}) = 240 \text{ kips} \]

Service load:
\[ P_a = 40 \text{ kips} + 120 \text{ kips} = 160 \text{ kips} \]

**Section Properties**

Built-up section properties (ignoring fillet welds):
\[ A_g = 2(10.5)(0.375) + 7.25(0.25) = 9.69 \text{ in}^2 \]
\[ I_x = \sum A d^2 + 2 \frac{bh^3}{12} = 2\left[10.5 \times 0.375(3.81)^2 + \frac{10.5(0.25)^3}{12}\right] + \frac{0.25(7.25)^3}{12} = 122 \text{ in}^4 \]
\[ I_y = 2\left(\frac{0.375 \times 10.5^3}{12}\right) + \frac{7.25 \times 0.25^3}{12} = 72.4 \text{ in}^4 \]
\[ r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{72.4}{9.69}} = 2.73 \text{ in} \]

From the User Note in Section E4 of Reference 1:
\[ C_w = \frac{I_y h_o^2}{4} = \frac{72.4(7.63)^2}{4} = 1,050 \text{ in}^6 \]

From Eq. 3.4 in Reference 3:
\[ J = \sum b t^3 = 2(10.5)(0.375)^3 + 7.25(0.25)^3 = 0.407 \text{ in}^4 \]

**Slenderness**

Check for slender web and then determine the stiffened element (web) reduction factor.

Web slenderness:
\[ \lambda = \frac{h}{t} = \frac{7.25}{0.25} = 29.0 \]

The limiting web slenderness ratio, \( \lambda_r \):
\[ \lambda_r = 1.49 \sqrt{\frac{E}{F_y}} = 1.49 \sqrt{\frac{29,000}{50,000}} = 35.9 > \lambda \]

Thus, the web is not slender and there is no reduction (i.e., \( Q_a 1.0 \))

Check for slender flanges and then determine the unstiffened element (flange) reduction factor.

\[ k_c = \frac{4}{\sqrt{h / t_w}} = \frac{4}{\sqrt{7.25 / 0.25}} = 0.743 \]

\[ 0.35 < k_c < 0.76, \text{ OK.} \]

Flange slenderness:
\[ \lambda = \frac{b}{t} = \frac{5.25}{0.375} = 14.0 \]

The limiting flange slenderness ratio, \( \lambda_r \):
\[ \lambda_r = 0.64 \sqrt{\frac{k_c E}{F_y}} = 0.64 \sqrt{\frac{0.743(29,000)}{50}} = 13.3 < \lambda \]
Thus, the flanges are slender.

\[
0.64 \sqrt{\frac{K_c E}{F_y}} = 13.3 < \frac{b_t}{r} = 14.0 < 1.17 \sqrt{\frac{K_c E}{F_y}} = 1.17 \sqrt{\frac{0.743(29,000)}{50}} = 24.3
\]

\[
Q_s = 1.415 - 0.65 \left( \frac{b_t}{r} \right) \sqrt{\frac{F_y}{K_c E}} = 1.415 - 0.65(14.0) \sqrt{\frac{50}{0.743(29,000)}} = 0.977
\]

\[
Q = Q_s Q \alpha = 0.977(1.0) = 0.977
\]  

(Eq. E7-8)

Elastic Flexural Buckling Stress

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

\[
\frac{K_y L}{r_y} = \frac{1.0(15.0)(12)}{2.73} = 65.9
\]

\[
F_e = \frac{n^2 E}{(KL/r)^2} = \frac{n^2 29,000}{(65.9)^2} = 65.9 \text{ ksi}
\]  

(Eq. E3-4)

Nominal Compressive Strength

\[
\frac{KL}{r} = 65.9 < 4.71 \sqrt{\frac{E}{Q F_y}} = 4.71 \sqrt{\frac{29,000}{0.977(50)}} = 115
\]

\[
F_{cr} = Q \left[ 0.658 \frac{Q F_y}{F_e} \right] F_y = 0.977 \left[ 0.658 \frac{0.977(50)}{65.9} \right] 50 = 35.8 \text{ ksi}
\]  

(Eq E7-2)

\[
P_n = F_{cr} A_g = 35.8(6.69) = 347 \text{ kips}
\]  

(Eq E7-1)

The available compressive strength:

LRFD: \( \phi_c P_n = 0.90(347) = 312 \text{ kips} \)

ASD: \( \frac{P_n}{\Omega_c} = \frac{347}{1.67} = 208 \text{ kips} \)

**V. AISC 360-10 Double L E.5**

*Reference*

*Note:* This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf)

*Related Links*
- *D1.A.5.2 Axial Compression* (on page 1086)

*Problem*

From the reference:

Verify the strength of a 2L 4×3-1/2×3/8 LLBB (3/8-in. separation) strut, ASTM A36, with a length of 8 ft and pinned ends carrying an axial dead load of 20 kips and live load of 60 kips.

Refer to the reference for calculations.
**Comparison**

---
V. AISC 360-10 Double L E.6

Verify the compressive strength of an unbraced wide-flange section column about the Y-Y axis per the LRFD and ASD methods of the AISC 360-10 code.

References

Related Links

- D1.A.5.2 Axial Compression (on page 1086)

Details

From the reference example E.1C:

Determine if a 2L5×3×1/4 LLBB (3/4-in. separation) strut, ASTM A36, with a length of 8 ft and pinned ends has sufficient available strength to support a dead load of 10 kips and live load of 30 kips in axial compression. Also, calculate the required number of pretensioned bolted or welded intermediate connectors.
Validation

Ultimate load:

\[ P_u = 1.2(10 \text{ kips}) + 1.6(30 \text{ kips}) = 60 \text{ kips} \]

Service load:

\[ P_a = 10 \text{ kips} + 30 \text{ kips} = 40 \text{ kips} \]

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

Slenderness

\[ \lambda = \frac{b}{t} = \frac{5.0}{0.25} = 20.0 \]

The limiting slenderness ratio, \( \lambda_r \):

\[ \lambda_r = 0.45 \sqrt{\frac{E}{F_y}} = 0.45 \sqrt{\frac{29,000}{36}} = 12.8 < \lambda \]  

(Table B4.1a, case 3)

Thus, the outstanding legs are slender.

Check for slender web and then determine the stiffened element (web) reduction factor.

\[ 0.45 \sqrt{\frac{E}{F_y}} = 12.8 < \frac{b}{t} = 20.0 < 0.91 \sqrt{\frac{E}{F_y}} = 0.91 \sqrt{\frac{29,000}{36}} = 25.8 \]  

(Eq. E7-11)

\[ Q_s = 1.34 - 0.76 \left( \frac{b}{t} \right) \frac{F_y}{E} = 1.34 - 0.76(20.0)\sqrt{\frac{36}{29,000}} = 0.804 \]

\[ Q = Q_s Q_a = 0.804(1.0) = 0.804 \]

\[ F_{cr} = Q(0.658 \frac{Q F_y}{F}) \]

where

\[ F_e = \left( \frac{F_{ey} + F_{ez}}{2H} \right) \left[ 1 - \sqrt{1 - \frac{4F_{ey} F_{ez} H}{(F_{ey} + F_{ez})^2}} \right] \] (Eq E4-5)

\[ K_i = 0.5 \text{ for angles back-to-back} \]

\[ r_i = r_x = 0.652 \text{ in}; \text{ the radius of gyration for a single angle} \]

\[ a = 32 \text{ in spacing between connectors (using the bolts at 1/3 points from Reference 2)} \]

\[ \left( \frac{K_y L}{r_y} \right)_m = \sqrt{\left( \frac{K L}{r} \right)^2 + \left( \frac{K_i a}{r_i} \right)^2} = \sqrt{\left( \frac{1.0 \times 96}{1.33} \right)^2 + \left( \frac{0.5 \times 32}{0.652} \right)^2} = 76.3 \text{ for} \]

\[ \frac{a}{r_i} = \frac{32 \text{ in}}{0.652 \text{ in}} = 49.1 > 40 \]

\[ F_{ey} = \frac{n^2 E}{K_y L} \frac{r_y}{m} = \frac{11,200(0.04328) \times 2 \text{ angles}}{3.88(2.59)^2} = 49.2 \text{ ksi} \]

\[ F_{ez} = \frac{GJ}{A \phi \theta^2} = \frac{377}{3.88(2.59)^2} = 37.7 \text{ ksi} \]

Thus,

\[ 26.8 \text{ ksi} \]

Nominal Compressive Strength
The available compressive strength:

LRFD: $\phi_c P_n = 0.90(71.4) = 64.3$ kips

ASD: $P_n / \Omega_c = \frac{71.4}{1.67} = 42.8$ kips

Note: STAAD.Pro does not perform design per Section E6 of the specification. It is assumed that sufficient intermediate connectors of an appropriate type are present. It is left to the engineer to verify the intermediate connector design.

STAAD. Pro Code Checking - (AISC-360-10-ASD) v1.4a

**All Units Are - KIP INCH (UNLESS OTHERWISE Noted)**
V. AISC 360-10 WT E.7

Verify the compressive strength of a WT section per the LRFD and ADS methods of the AISC 360-10 codes.

References

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Related Links

• D1.A.5.2 Axial Compression (on page 1086)

Details

From reference (2):

Select an ASTM A992 nonslender WT-shape compression member with a length of 20 ft to support a dead load of 20 kips and live load of 60 kips in axial compression. The ends are pinned.

See example E.7 in reference (2) for calculations.

V. AISC 360-10 Rect HSS E.9

Verify the compressive strength of an unbraced column with a rectangular HSS section per the LRFD and ASD methods of the AISC 360-10 code.

References

Related Links
• D1.A.5.2 Axial Compression (on page 1086)

Details
From reference (2):

Select an ASTM A500 Grade B rectangular HSS compression member, with a length of 20 ft, to support a dead load of 85 kips and live load of 255 kips in axial compression. The base is fixed and the top is pinned.

Validation
Ultimate load:

\[ P_u = 1.2(85 \text{ kips}) + 1.6(255 \text{ kips}) = 510 \text{ kips} \]

Service load:

\[ P_a = 85 \text{ kips} + 255 \text{ kips} = 340 \text{ kips} \]

Slenderness

Note: The corner radius is taken as 1.5× the design wall thickness per Section B4.1b of Reference 1.

\[ \lambda = \frac{h}{r} = \frac{12.0 - 3(0.349)}{0.349} = 31.4 \]

The limiting slenderness ratio, \( \lambda_r \):

\[ \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{46}} = 35.2 > \lambda \]  

(Table B4.1a, case 3)

Thus, the section does not contain slender elements.

Per Table C-A-7.1 in Reference 1, \( K = 0.8 \) for fixed-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

\[ \frac{K_{yL}}{r_y} = \frac{0.8(20)(12)}{4.91} = 47.9 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{46}} = 118 \]

\[ F_e = \frac{n^2E}{(K_{yL})^2} = \frac{n^2(29,000)}{(47.9)^2} = 125 \text{ ksi} \]  

(Eq. E3-4)
\[ F_{cr} = \left( 0.658 \frac{F_y}{F_e} \right) F_y = (0.658 \frac{46}{125}) 46 = 39.4 \text{ ksi} \]  
(Eq. E3-2)

Nominal Compressive Strength

\[ P_n = F_{cr} A_g = 39.4(14.6) = 575 \text{ kips} \]  
(Eq E7-1)

The available compressive strength:

LRFD: \(\phi P_n = 0.90(575) = 518 \text{ kips}\)

ASD: \(\frac{P_n}{\Omega_c} = \left(\frac{575}{1.67}\right) = 344 \text{ kips}\)

### Verification Examples

#### V. AISC 360-10 Pipe E.11

Verify the compressive strength of a pipe section braced at the midpoint in the Y-Y direction per the LRFD and ADS methods of the AISC 360-10 codes.

#### References

Select an ASTM A53 Grade B Pipe compression member with a length of 30 ft to support a dead load of 35 kips and live load of 105 kips in axial compression. The column is pin-connected at the ends in both axes and braced at the midpoint in the y-y direction.

Validation

Ultimate load:

\[ P_u = 1.2(35 \text{ kips}) + 1.6(105 \text{ kips}) = 210 \text{ kips} \]

Service load:

\[ P_a = 35 \text{ kips} + 105 \text{ kips} = 140 \text{ kips} \]

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns.

\[
\left( \frac{KL}{r} \right)_x = \frac{1.0 \times 30 \times 12}{3.68} = 97.8 \\
\left( \frac{KL}{r} \right)_y = \frac{1.0 \times 15 \times 12}{3.68} = 48.9 
\]

So buckling about the x-x axis governs. For 35 ksi, no pipe sections are slender per Table 4-6 in Reference 1.

\[
\left( \frac{KL}{r} \right)_{\text{max}} = 97.8 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{35}} = 136 
\]

The critical stress

\[
F_e = \frac{n^2 E}{(KL/r)^2} = \frac{n^2 29,000}{(97.8)^2} = 29.9 \text{ ksi} \quad \text{(Eq. E3-4)} 
\]

Nominal Compressive Strength

\[
F_{cr} = \left( 0.658 \frac{F_y}{F_e} \right) F_y = 0.804 \left[ 0.658 \frac{35}{29.9} \right] 35 = 21.4 \text{ ksi} \quad \text{(Eq E7-2)} 
\]

\[
P_n = F_{cr} A_g = 21.4(11.5) = 246 \text{ kips} \quad \text{(Eq E7-1)} 
\]

The available compressive strength:

LRFD: \( \phi_c P_n = 0.90(246) = 221 \text{ kips} \)

ASD: \( P_n / QC = \frac{246}{1.67} = 147 \text{ kips} \)

**V. AISC 360-10 Built Up I E 12**

Verify the compressive strength of a built-up I section with different flange widths per the LRFD and ADS methods of the AISC 360-10 codes.

**References**

**Related Links**

- [D1.A.5.2 Axial Compression](#) (on page 1086)

**Details**

From reference (2):

Compute the available strength of a built-up compression member with a length of 14 ft. The ends are pinned. The outside flange is PL3/4-in.×5-in.,
the inside flange is PL3/4-in.×8-in., and the web is PL3/8-in.×10 1/2-in.
Material is ASTM A572 Grade 50.

**Validation**

**Material Properties**

\[ F_y = 50 \text{ ksi} \]
\[ F_u = 65 \text{ ksi} \]

**Section Properties**

Built-up section properties (ignoring fillet welds):

\[ A_g = 8.0(0.75) + 10.5(0.375) + 5.0(0.75) = 13.7 \text{ in}^2 \]
\[ \bar{y} = \frac{\sum A_i y_i}{\sum A_i} = \frac{6.0(11.6) + 3.94(6.0) + 3.75(0.375)}{6.0 + 3.94 + 3.75} = 6.91 \text{ in} \]

where \( \bar{y} \) is measured from the bottom of the outside flange.

\[ I_x = 8.0(0.75)(4.72)^2 + \frac{8.0(0.75)^3}{12} + \frac{0.375(10.5)(0.910)^2 + 0.375(10.5)^3}{12} + \frac{5.0(0.75)(6.54)^2 + 5.0(0.75)^3}{12} = 334 \text{ in}^4 \]
\[ I_y = \frac{0.75 \times 8.0^3}{12} + \frac{10.5 \times 0.375^3}{12} + \frac{0.75 \times 5.0^3}{12} = 39.9 \text{ in}^4 \]
\[ r_x = \sqrt{\frac{I_x}{A}} = \sqrt{\frac{334}{13.7}} = 4.94 \text{ in} \]
\[ r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{39.9}{13.7}} = 1.71 \text{ in} \]

From Eq. 3.4 in Reference 3:

\[ J = \sum \frac{b_t^3}{3} = \frac{8.0(0.75)^3 + 10.5(0.375)^3 + 5.0(0.75)^3}{3} = 2.01 \text{ in}^4 \]

Distance between flange centroids:

\[ h_0 = 12.0 - \frac{0.75}{2} - \frac{0.75}{2} = 11.3 \text{ in} \]
\[ C_w = \frac{t_fh_o^2}{12} \left( \frac{b_1^3b_2^3}{b_1^3 + b_2^3} \right) = \frac{0.75(11.3)^2}{12} \left[ \frac{(8.0)^3(5.0)^3}{(8.0)^3 + (5.0)^3} \right] = 802 \text{ in}^6 \]

Due to symmetry about the \( y \)-axis, the shear center lies on the \( y \) axis (\( x_0 = 0 \)). The distance from the centroid to the shear center can be calculated by finding the shear center from outside flange plus one-half the outside flange and then subtracting the centroid distance from that same reference point.

\[ y_0 = (e + \frac{t_f}{2}) - \bar{y} = h_0 \left[ \frac{b_1^3}{b_1^3 + b_2^3} \right] + \frac{t_f}{2} - \bar{y} = 11.3 \left[ \frac{(8.0)^3(5.0)^3}{(8.0)^3 + (5.0)^3} \right] + \frac{0.75}{2} - 6.91 = 2.55 \text{ in} \]
\[ \bar{r}_0^2 = x_0^2 + y_0^2 + \frac{I_x + I_y}{A_g} = (2.55)^2 + \frac{344 + 39.9}{13.7} = 33.8 \text{ in}^2 \]
\[ H = 1 - \frac{x_0^2 + y_0^2}{r_0^2} = 1 - \frac{0 + (2.55)^2}{33.8} = 0.808 \]

Elastic Flexural Buckling Stress

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the \( y-y \) axis governs.

\[
\frac{K_y L}{r_y} = \frac{1.0(14.0)(12)}{1.71} = 98.2 \quad \text{(Eq. E4-8)}
\]

\[
F_{ey} = \frac{n^2 E}{(KL/r_y)^2} = \frac{n^2 29,000}{(98.2)^2} = 29.7 \text{ ksi} \quad \text{(Eq. E4-8)}
\]

\[
F_{ez} = \left[ \frac{n^2 E C_w}{(K_z L)^2} + GJ \right] \left( \frac{1}{A_f L} \right) = \left[ \frac{n^2 (29,000)(802)}{(1.0 \times 14.0 \times 12)^2} + 11,200(2.01) \right] \left( \frac{1}{13.7 \times 33.8} \right) = 66.2 \text{ ksi E4-9)}
\]

\[
F_e = \left( \frac{F_{ey} + F_{ez}}{2H} \right) \left[ 1 - \frac{1 - 4F_{ey} F_{ez} H}{(F_{ey} + F_{ez})^2} \right] = \left( \frac{29.7 + 66.2}{2 \times 0.808} \right) \left[ 1 - \frac{1 - 4(29.7)(66.2)(0.808)}{(29.7 + 66.2)^2} \right] = 26.4 \text{ ksi E4-5)}
\]

Nominal Compressive Strength

\[
F_y = \frac{50}{2.25} = 22.2 \text{ ksi < 26.4 ksi} \quad \text{(Eq E7-2)}
\]

\[
F_{cr} = (0.658 F_{y}/F_e) F_y = [0.658(50/26.4)]50 = 22.6 \text{ ksi} \quad \text{(Eq E7-1)}
\]

\[
P_n = F_{cr} A_g = 22.6(13.7) = 310 \text{ kips} \quad \text{(Eq E7-1)}
\]

The available compressive strength:

LRFD: \( \phi_c P_n = 0.90(310) = 279 \text{ kips} \)

ASD: \( P_n / \Omega_c = \frac{310}{1.67} = 186 \text{ kips} \)

**Reference**

**Note:** This reference is freely available for download from the AISC website at [https://www.aisc.org/globalassets/aisc/university-programs/teaching-aid/first-semester-design-examples.pdf](https://www.aisc.org/globalassets/aisc/university-programs/teaching-aid/first-semester-design-examples.pdf)

**Related Links**

- *D1.A.5.5 Design for Combined Forces* (on page 1089)

**Objective**

From the reference:

Using AISC Manual tables to determine the available compressive and flexural strengths, determine if an ASTM A992 W14×99 has sufficient available strength to support the axial forces and moments listed as follows, obtained from a second-order analysis that includes P-δ effects. The unbraced length is 14 ft and the member has pinned ends. KLx = KLy = Lb = 14.0 ft.
Refer to the reference for calculations.

**Note:** A static analysis is used in STAAD.Pro as the reference supplies only the resulting forces from an assumed P-δ analysis.

### STAAD SPACE

-- PAGE NO.
V. AISC 360-10 W Tens BM H3

Verify the interaction checks due to tension and bending moments in both axes of a W section per the LRFD and ASD methods of the AISC 360-10 code.

References

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Related Links

- D1.A.5.5 Design for Combined Forces (on page 1089)

Details

From reference (2):

Select an ASTM A992 W-shape with a 14-in. nominal depth to carry forces of 29.0 kips from dead load and 87.0 kips from live load in axial tension, as well as the following moments due to uniformly distributed loads:

- \( M_{xD} = 32.0 \text{ kip-ft} \)
- \( M_{xL} = 96.0 \text{ kip-ft} \)
- \( M_{yD} = 11.3 \text{ kip-ft} \)
- \( M_{yL} = 33.8 \text{ kip-ft} \)

The unbraced length is 30.0 ft and the ends are pinned. Assume the connections are made with no holes.

See example H.3 in reference (2) for calculations.

V. AISC 360-10 HSST Torsional Strength H.5A

Verify the torsional strength of a rectangular HSS section per the LRFD and ASD methods of the AISC 360-10 code.

References

Related Links
- D1.A.5.6 Design for Torsion (on page 1089)

Details
From reference (2):

```
Determine the available torsional strength of an ASTM A500 Grade B HSS6×4×1/4.
```

Validation

\( h/t > b/t \), so \( h/t \) governs.
\[
\frac{h}{T} = 22.8 < 2.45\sqrt{\frac{E}{F_y}} = 2.45\sqrt{\frac{29,000}{46}} = 61.5
\]

\[F_{cr} = 0.6F_y = 0.6(46) = 27.6 \text{ ksi} \quad \text{(Eq. H3-3)}\]

Nominal Torsional Strength

\[T_n = F_{cr}C = 27.6(10.1) = 279 \text{ in} \cdot \text{k} \quad \text{(Eq. G2-1)}\]

The available shear strength:

LRFD: \(\phi_T T_n = 0.90(279) = 251 \text{ in} \cdot \text{k}\)

ASD: \(\frac{T_n}{\Omega_T} = \frac{279}{1.67} = 167 \text{ in} \cdot \text{k}\)

### V. AISC 360-10 HSSP Torsional Strength H.5B

Verify the torsional strength of an round HSS section per the LRFD and ASD methods of the AISC 360-10 code.

#### References

**Related Links**
- D1.A.5.6 Design for Torsion (on page 1089)

**Details**
From reference (2):

Determine the available torsional strength of an ASTM A500 Grade B HSS 5.000×0.250 that is 14 ft long.

**Validation**

**Critical Stress**

\[
F_{cr} = \max \left( \frac{1.23E}{\left( \frac{D}{t} \right)^{5/4}} = \frac{1.23(29,000)}{\sqrt[4]{14 \times 12}} = 133 \text{ ksi} \right)
\]

\[
= \max \left( \frac{0.60E}{\left( \frac{D}{t} \right)^{3/2}} = \frac{0.60(29,000)}{(21.5)^{3/2}} = 175 \text{ ksi} \right)
\]

The maximum permitted value is \( F_{cr} \leq 0.6F_y = 0.6(42) = 25.2 \text{ ksi} \) (governs).

**Nominal Torsional Strength**

\[
T_n = F_{cr}C = 25.2(7.95) = 200 \text{ in} \cdot \text{k}
\]  
(Eq. G2-1)

The available shear strength:

LRFD: \( \phi_T T_n = 0.90(200) = 180 \text{ in} \cdot \text{k} \)

ASD: \( T_n / \Omega_T = \frac{200}{1.67} = 120 \text{ in} \cdot \text{k} \)

V. AISC 360-10 W Shape Strong Axis Shear G.1

Verify the available shear strength along the strong axis of a wide flange section per the LRFD and ASD methods of the AISC 360-10 code.

References

Verification Examples
V.09 Steel Design

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Details
From reference (2):

Determine the available shear strength and adequacy of a W24×62 ASTM A992 beam ... with end shears of 48 kips from dead load and 145 kips from live load.

See example G.1A and G.1B in reference (2) for calculations.

• D1.A.5.4 Design for Shear (on page 1087)

Details
From reference (2):

Verify the available shear strength and adequacy of a C15×33.9 ASTM A36 channel with end shears of 17.5 kips from dead load and 52.5 kips from live load.

See example G.2A and G.2B in reference (2) for calculations.

**Verification Examples**

**V. AISC 360-10 L Shear Capacity G.3**

Verify the available shear strength along the strong axis of a single angle section per the LRFD and ASD methods of the AISC 360-10 code.

**References**

**Related Links**

- *D1.A.5.4 Design for Shear* (on page 1087)

**Details**

From reference (2):
Determine the available shear strength and adequacy of a L5×3×1/4 (LLV) ASTM A36 with end shears of 3.50 kips from dead load and 10.5 kips from live load.

**Validation**

Ultimate load:

\[ V_u = 1.2(3.50 \text{ kips}) + 1.6(10.5 \text{ kips}) = 21.0 \text{ kips} \]

Service load:

\[ V_a = 3.50 \text{ kips} + 10.5 \text{ kips} = 14.0 \text{ kips} \]

Area of the web for shear:

\[ A_w = bt = 5.0(0.25) = 1.25 \text{ in}^2 \]

Section G4 of Reference 1 gives \( k_v = 1.2 \).

\[ \frac{h}{t_w} = \frac{b}{t} = \frac{5.0}{0.25} = 20 < 1.10 \sqrt{\frac{k_v F_y}{1.2(29,000)}} = 34.2 \]

Therefore, \( C_v = 1.0 \).

**Nominal Shear Strength**

\[ V_n = 0.6F_yA_wC_v = 0.6(36)(1.25)(1.0) = 27.0 \text{ kips} \]  
(Eq. G2-1)

The available shear strength:

LRFD: \( \phi_v V_n = 0.90(27.0) = 24.3 \text{ kips} \)

ASD: \( V_n / \Omega_v = \frac{27.0}{1.67} = 16.2 \text{ kips} \)

**Results**

V. AISC 360-10 HSST Shear Capacity G.4

Verify the available shear strength along the strong axis of a rectangular HSS section per the LRFD and ASD methods of the AISD 360-10 code.

References

Related Links
• D1.A.5.4 Design for Shear (on page 1087)

Details
From reference (2):

Determine the available shear strength and adequacy of an HSS6×4×3/8 ASTM A500 Grade B member with end shears of 11.0 kips from dead load and 33.0 kips from live load. The beam is oriented with the shear parallel to the 6 in. dimension.

Validation
Ultimate load:

\[ V_u = 1.2(11.0 \text{ kips}) + 1.6(33.0 \text{ kips}) = 66.0 \text{ kips} \]

Service load:

\[ V_a = 11.0 \text{ kips} + 33.0 \text{ kips} = 44.0 \text{ kips} \]

Area of the web for shear:

**Note:** The corner radius is taken as 1.5× the design wall thickness per Section B4.1b of Reference 1.

\[ h = H - 3t = 6.0 - 3 \times 0.349 = 4.95 \text{ in} \]
Section G5 of Reference 1 gives $k_v = 5$.

$$A_w = 2ht = 2(4.95)(0.349) = 3.46 \text{ in}^2$$

$$\frac{h}{t_w} = \frac{4.95}{0.349} = 14.2 < 1.10 \sqrt{\frac{k_v E}{F_y}} = 1.10 \sqrt{\frac{5(29,000)}{46}} = 61.8$$

Therefore, $C_v = 1.0$.

**Nominal Shear Strength**

$$V_n = 0.6F_y A_w C_v = 0.6(46)(3.46)(1.0) = 95.5 \text{ kips} \quad (\text{Eq. G2-1})$$

The available shear strength:

**LRFD**: $\phi V_n = 0.90(95.5) = 86.0 \text{ kips}$

**ASD**: $\frac{V_n}{Q_v} = \frac{95.5}{1.67} = 57.2 \text{ kips}$

STAAD.PRO CODE CHECKING - ( AISC-360-10-ASD) v1.4a

---

ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted)
V. AISC 360-10 HSSP Shear Capacity G.5

Verify the available shear strength along the strong axis of a round HSS section per the LRFD and ASD methods of the AISD 360-10 code.

References

Related Links

• D1.A.5.4 Design for Shear (on page 1087)

Details

From reference (2):

Verify the available shear strength and adequacy of a round HSS16.000×0.375 ASTM A500 Grade B member spanning 32 ft with end shears of 30.0 kips from dead load and 90.0 kips from live load.
Validation

Ultimate load:

\[ V_u = 1.2(30.0 \text{ kips}) + 1.6(90.0 \text{ kips}) = 180 \text{ kips} \]

Service load:

\[ V_a = 30.0 \text{ kips} + 90.0 \text{ kips} = 120 \text{ kips} \]

Shear Buckling Stress

\[ F_{cr} = \frac{1.60E}{\sqrt{\frac{L_v}{D}\frac{D}{t}}^{\frac{3}{4}}} = \frac{1.60(29,000)}{\sqrt{192^{\frac{3}{4}} 16.0^{\frac{3}{4}}}} = 112 \text{ ksi} \]

\[ F_{cr} = \frac{0.78E}{\sqrt{\frac{D}{t}}^{\frac{3}{2}}} = \frac{0.78(29,000)}{\sqrt{16.0^{\frac{3}{2}} 0.349}} = 72.9 \text{ ksi} \]

The maximum permitted value is \( F_{cr} \leq 0.6F_y = 0.6(42) = 25.2 \text{ ksi} \) (governs).

Nominal Shear Strength

\[ V_n = F_{cr} A_g / 2 = (25.2)(17.2) / 2 = 217 \text{ kips} \]  

(Eq. G2-1)

The available shear strength:

LRFD: \( \phi_v V_n = 0.90(217) = 195 \text{ kips} \)

ASD: \( V_n / \Omega_v = \frac{217}{1.67} = 130 \text{ kips} \)

Problem
From the reference:

Verify the available shear strength and adequacy of a W21×48 ASTM A992 beam with end shears of 20.0 kips from dead load and 60.0 kips from live load in the weak direction.

Refer to the reference for calculations.

**All units are - KIP, FEET (unless otherwise noted)**
Details

A 5' × 5' portal frame consists of W12x72 columns and a steel tapered member for the beam.

The following load cases are evaluated:

1. A uniformly distributed load of -3.5 k/ft along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. Lateral loads at the top of the right column of -50 kips in the global X direction and 45 kips in the global Z direction (out of plane).

4. A concreted load of -100 kips in the global Y direction and a concentrated torque of 9 in·kips at mid-span of the beam.

Material Properties

- \( E = 29,000 \) ksi
- \( F_y = 50 \) ksi

**Validation**

**Design Forces**

By inspection, the left end of the beam (shallowest overall depth) governs under the symmetric loads present. The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 32.26 \) in·kips, \( F_y = 8.755 \) kips
2. \( M_z = 677.6 \) in·kips, \( M_y = 2.942 \) in·kips, \( M_x = 5.106 \) in·kips, \( F_y = 22.49 \) kips, \( F_z = 0.098 \) kips, \( F_x = 24.70 \) kips
3. \( M_z = 275.9 \) in·kips, \( M_x = 4.497 \) in·kips, \( F_y = 50.23 \) kips, \( F_x = 5.473 \) kips
4. \( M_z = 654.5 \) in·kips, \( M_y = 5.298 \) in·kips, \( M_x = 9.192 \) in·kips, \( F_y = 22.50 \) kips, \( F_z = 0.177 \) kips, \( F_x = 24.35 \) kips

**Section Properties**

The section at the left end \((D = 18 \) in.) has the following properties:

- Web height, \( d_w = 18 - 2 \times 0.84 = 16.32 \) in.
- Area, \( A_g = (0.84)(9 + 7.5) + 16.32 \times 0.36 = 19.74 \) in

- Shear area in local y, \( A_y = 16.32 \times 0.36 = 5.875 \) in
- Shear area in local x, \( A_x = 0.84(9 + 7.5) = 13.86 \) in

- Dist to centroid y, \( c = \frac{7.5 \times 0.84 \times 0.84 + 0.36 \times 16.32 \times 0.84 + 9 \times (18 - 0.84)}{19.74} = 9.548 \) in.

- Moment of inertia about major axis, \( I_{zz} = \frac{7.5(0.84)^3}{12} + 7.5(0.84)(9.548 - 0.84)^2 \)

- Mean of inertia about minor axis, \( I_{yy} = \frac{80.62}{12} = 6.72 \) in

- Elastic section modulus about major axis top flange fiber, \( S_{xx,\text{top}} = \frac{I_{zz}}{D - c} = \frac{1,146}{18 - 9.548} = 135.5 \) in

- Elastic section modulus about major axis bottom flange fiber, \( S_{xx,\text{bottom}} = \frac{I_{zz}}{c} = \frac{1,146}{9.548} = 120.0 \) in

- Elastic section modulus about minor axis, \( S_{yy} = \frac{I_{yy}}{b_f l_f / 2} = \frac{80.62}{9 / 2} = 17.39 \) in
Radius of gyration about major axis, \( r_x = \sqrt{\frac{I_z}{A_g}} = \sqrt{\frac{1.137}{19.74}} = 7.619 \text{ in} \)

Radius of gyration about minor axis, \( r_y = \sqrt{\frac{I_y}{A_g}} = \sqrt{\frac{80.62}{19.74}} = 7.619 \text{ in} \)

Location of the plastic neutral axis, \( y_{PNA} = 0.84 + \frac{19.74 - 2(7.5)(0.84)}{2 \times 0.36} = 10.75 \text{ in.} \)

Plastic section modulus about major axis, \( Z_z = \frac{7.5(10.75)^2}{2} \left( \frac{7.5 \cdot 0.36}{2} (10.75 \cdot 0.84) \right)^2 + \frac{9(18 \cdot 10.75)^2}{2} \left( \frac{9 \cdot 0.36}{2} (18 \cdot 0.84 - 10.75)^2 \right)^2 = 141.8 \text{ in}^3 \)

Plastic section modulus about minor axis, \( Z_y = \frac{0.84(9)^2}{4} + \frac{16.32(0.36)^2}{4} + \frac{0.84(7.5)^2}{4} = 29.35 \text{ in}^3 \)

Torsional constant, \( J = \frac{9(0.84)^3 + 16.32(0.36)^3 + 7.5(0.84)^3}{3} = 3.514 \text{ in}^4 \)

**Section Classification**

Flange in compression

\[ \lambda = \frac{b}{t} = \frac{1/2 \times 7.5}{0.84} = 4.464 \]

\[ k_c = \frac{4}{\sqrt{\frac{d_w}{t_w}}} = \frac{4}{\sqrt{\frac{16.32}{0.36}}} = 0.594 \]

Per Table B4.1a, \( \lambda < \lambda_r = 0.64 \sqrt{\frac{k_c E}{F_y}} = 0.64 \sqrt{\frac{0.594(29,000)}{50}} = 11.88 \), therefore flanges are non-slender for compression.

Web in compression

\[ \lambda = \frac{d_w}{t_w} = \frac{16.32}{0.36} = 45.33 \]

Per Table B4.1a, Case 5, \( \lambda > \lambda_r = 1.49 \sqrt{\frac{E}{F_y}} = 1.49 \sqrt{\frac{29,000}{50}} = 35.88 \), therefore the web is slender for compression.

Flange in bending (use half the longer flange width as the outstanding width):

\[ \lambda = \frac{b_f}{t_f} = \frac{9}{2(0.84)} = 5.36 \]

Per Table B4.1b, Case 11, \( \lambda < \lambda_p = 0.38 \sqrt{\frac{E}{F_y}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15 \), therefore flange is compact for bending.

Web in bending

\[ \lambda = \frac{d_w}{t_w} = \frac{16.32}{0.36} = 45.33 \]

Per Table B4.1b, Case 15, \( \lambda < \lambda_p = 3.76 \sqrt{\frac{E}{F_y}} = 3.76 \sqrt{\frac{29,000}{50}} = 90.55 \), therefore web is compact for bending.
Compression Capacity

About X Axis:

\[ \frac{k_x L_x}{r_x} = \frac{1.0(60)}{7.619} = 7.875 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

\[ F_{ex} = \frac{n^2E}{(k_x L_x)^2} = \frac{n^2 \times 29,000}{(7.875)^2} = 4.615 \text{ ksi} \]  

(Eq. E3-4)

\[ F_{ex}^{\frac{F_y}{F_{ex}}} = \frac{50}{4.615} = 0.011 < 2.25 \]  

(Eq. E3-2)

\[ F_{crx} = 0.658 \frac{F_{ex}}{F_y} = 0.658^{(0.011)}50 = 49.77 \text{ ksi} \]

Since the web is slender, use the effective area. The effective width imperfection adjustment factors (Table E7.1):

\[ c_1 = 0.18 \]

\[ c_2 = 1.31 \]

\[ F_{el} = \left( \frac{c_2}{\lambda} \right)^2 F_y = \left( \frac{1.31}{35.88} \right)^2 = 53.76 \text{ ksi} \]  

(Eq. E7-5)

Therefore, the effective depth of the web in compression for the effective area:

\[ d_e = d_w \left( 1 - c_1 \frac{F_{el}}{F_{crx}} \right) \frac{F_{el}}{F_{crx}} = 16.32 \left( 1 - 0.18 \sqrt{\frac{53.76}{49.77}} \right) \frac{53.76}{49.77} = 13.78 \text{ in.} \]  

(Eq. E7-3)

The reduced area of the section then becomes:

\[ A_e = 19.75 \times (16.32 \times 13.78)0.36 = 18.84 \text{ in.}^2 \]

\[ P_{nx} = A_e \times F_{crx} = 18.84 \times 49.77 = 937.4 \text{ kips} \]  

(Eq. E7-1)

About Y Axis:

\[ \frac{k_y L_y}{r_y} = \frac{1.0(60)}{2.021} = 29.69 < 4.71 \sqrt{\frac{E}{F_y}} = 113.4 \]

\[ F_{ey} = \frac{n^2E}{(k_y L_y)^2} = \frac{n^2 \times 29,000}{(29.69)^2} = 324.7 \text{ ksi} \]  

(Eq. E3-4)

\[ F_{ey}^{\frac{F_y}{F_{ey}}} = \frac{50}{324.7} = 0.154 < 2.25 \]  

(Eq. E3-2)

\[ F_{cry} = 0.658 \frac{F_{ey}}{F_y} F_y = 0.658^{(0.154)}50 = 46.88 \text{ ksi} \]

Therefore, the effective depth of the web in compression for the effective area:

\[ d_e = d_w \left( 1 - c_1 \frac{F_{el}}{F_{crx}} \right) \frac{F_{el}}{F_{crx}} = 16.32 \left( 1 - 0.18 \sqrt{\frac{53.76}{46.88}} \right) \frac{53.76}{46.88} = 14.11 \text{ in.} \]  

(Eq. E7-3)

The reduced area of the section then becomes:
\[ A_e = 19.75 \times (16.32 \times 14.11) 0.36 = 18.93 \text{ in.}^2 \]

\[ P_{ny} = A_e \times F_{cy} = 18.93 \times 46.88 = 887.4 \text{ kips} \quad \text{(Eq. E7-1)} \]

The Y axis governs; \( P_n = P_{ny} \). The axial capacity:

- The ultimate compression capacity (LRFD) = \( \phi_c P_n = 0.9 \times 887.4 = 798.3 \text{ kips} \)
- The allowable compression capacity (ASD) = \( P_n / \Omega_c = 887.4 / 1.67 = 531.4 \text{ kips} \)

Calculate Bending Capacity

Bending capacity in plastic yielding about Y axis:

\[ M_y = F_y \times Z_y = 50 \times 29.35 = 1,468 \text{ in kips} > 1.6F_y \times S_y = 1.6 (50) (17.92) = 1,434 \text{ in kips} \]

Use \( M_y = 1,434 \text{ in kips} \)

The bending capacity for flexural yielding about the Y axis:

- The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 1,434 = 1,290 \text{ in kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,434 / 1.67 = 858.4 \text{ in kips} \)

Bending capacity in plastic yielding about X axis:

The section is capacity is determined as per F4 in the specification. The design moments for this are from Load Case 4 and occur at mid-span (d = 18.9 in.). The section properties at this location are:

\[ I_{zz} = 1,278 \text{ in}^4 \]
\[ I_{yy} = 80.63 \text{ in}^4 \]
\[ c = 10.01 \text{ in} \]
\[ h_c = 2 \times (10.01 - 0.84) = 18.35 \text{ in.} \]
\[ S_x = 143.8 \text{ in}^3 \]
\[ Z_x = 150.7 \text{ in}^3 \]

\[ M_{yc} = F_y \times S_{yc} = 50 \times 143.8 = 7,192 \text{ ksi} \]
\[ M_p = F_y \times Z_x = 50 \times 150.7 = 7,535 \text{ ksi} \leq 1.6 F_y \times S_x = 11,504 \text{ ksi} \]

The moment of inertia of the compression flange about the Y axis \( I_{yc} = \frac{0.84(7.5)}{72} = 29.53 \text{ in.}^4 \), and thus

\[ I_{yc} / I_y = \frac{29.53}{80.63} = 0.366 > 0.23, \quad \frac{h_c}{w} = \frac{18.35}{0.36} = 50.99 < \lambda_{pw} = 90.55 \] (limiting slenderness for a compact web per Table B4.1b case 15), so the web plastification factor, \( R_{pw} \), is determined as:

\[ R_{pw} = \frac{M_p}{M_{yc}} = \frac{7,535}{7,192} = 1.048 \quad \text{(F4-9a)} \]

Bending capacity in plastic yielding about Y axis:

\[ M_n = R_{pw} \times M_{yc} = 1.048 \times 7,192 = 7,535 \text{ in kips} \]

The bounding capacity for flexural yielding about the Y axis:

- The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 7,535 = 6,782 \text{ in kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 7,535 / 1.67 = 4,512 \text{ in kips} \)

Interaction Ratio for Bending and Compression
Check the interaction ratio for Load Case 3:

\[
\frac{P_r}{P_c} = \frac{5.473}{798.3} = 0.007 < 0.2 \text{ (LRFD)}
\]

\[
\frac{P_r}{P_c} = \frac{5.479}{531.4} = 0.010 < 0.2 \text{ (ASD)}
\]

So use Eq. H1-1b for both methods: \(\frac{P_r}{P_c} + \left(\frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}}\right) \leq 1.0\).

\[
\frac{0.007}{2} + \left(\frac{1.225}{6,783} + \frac{0}{1,290}\right) = 0.184 \text{ (LRFD)}
\]

\[
\frac{0.010}{2} + \left(\frac{1.225}{4,513} + \frac{0}{858}\right) = 0.277 \text{ (ASD)}
\]

### Verification Examples

STAAD.Pro 5265 User Manual
### V. AISC 360-10 Tapered Tube Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered tube section member per both the LRFD and ASD methods of the AISC 360-10 code.

**Details**

A 5' × 5' portal frame consists of W12x72 columns and a steel tapered member for the beam.
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concreted torque of 0.75 in-kips at mid-span of the beam.

Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ Fy = 50 \text{ ksi} \]

Validation

Design Forces

By inspection, the right end of the beam (shallowest overall depth) governs under the symmetric loads present. The following design loads are used from the STAAD.Pro analysis are then used:
\[ M_z = 505.66 \text{ in} \cdot \text{kips} \]
\[ F_y = 67.2 \text{ kips} \]
\[ F_x = 10.23 \text{ kips} \]

**Section Properties**

The section at the right end (\(OD = 10 \text{ in.}\)) has the following properties:

- Inner diameter, \(ID = 9 \text{ in.}\)
- Area, \(A_g = \frac{\pi}{4}(OD^2 - ID^2) = 14.92 \text{ in}^2\)
- Form factor, \(\lambda = 0.49 + 0.8 \left( \frac{t}{OD} \right) = 0.53\)
- Shear area, \(A_y = 14.92(0.53) = 7.909 \text{ in}^2\)
- Moment of inertia,
  \[ I = \frac{n}{64}(OD^4 - ID^4) = 168.8 \text{ in}^4\]
- Elastic section modulus, \(S = \frac{n}{32} \left( \frac{OD^3 - ID^3}{OD} \right) = 33.76 \text{ in}^3\)
- Radius of gyration, \(r = \sqrt{\frac{I}{A_g}} = \sqrt{\frac{168.8}{14.92}} = 3.363 \text{ in}\)
- Plastic section modulus, \(Z = \frac{OD^3 - ID^3}{6} = 45.17 \text{ in}^3\)
- HSS Torsional constant, \(C = \frac{n}{2}(OD - t)^2t = 70.88 \text{ in}^3\)

**Section Classification**

Flange in compression

\[ \lambda = \frac{OD}{t} = \frac{10}{0.5} = 20 \]

Per Table B4.1a, Case 9, \(\lambda < \lambda_r = 0.11 \frac{E}{F_y} = 63.8\), therefore flanges are non-slender for compression. The web is similarly non-slender for compression.

Flange in bending (use half the longer flange width as the outstanding width):

\[ \lambda = \frac{OD}{t} = \frac{10}{0.5} = 20 \]

Per Table B4.1b, Case 20, \(\lambda < \lambda_r = 0.07 \frac{E}{F_y} = 40.6\), therefore flange is compact for bending.

**Compression Capacity**

\[ \frac{kL}{r} = \frac{1.0(60)}{3.363} = 17.84 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

\[ F_e = \frac{n^2E}{(kL/r)^2} = \frac{n^2 \times 29,000}{(17.84)^2} = 899.4 \text{ ksi} \quad \text{(Eq. E3-4)} \]

\[ \frac{F_y}{F_e} = \frac{50}{899.4} = 0.056 < 2.25 \quad \text{(Eq. E3-2)} \]

\[ F_{crx} = 0.658 \left| \frac{F_y}{F_e} \right| = 0.658(0.056)50 = 48.85 \text{ ksi} \]
\[ P_n = A_g \times F_{cr} = 14.92 \times 48.85 = 729.0 \text{ kips} \]  
(Eq. E3-1)

The axial capacity:

The ultimate compression capacity (LRFD) = \[ \phi_c P_n = 0.9 \times 729.0 = 656.1 \text{ kips} \]

The allowable compression capacity (ASD) = \[ P_n / \Omega_c = 729.0 / 1.67 = 436.5 \text{ kips} \]

**Shear Capacity**

The distance from the maximum shear force (ends) to zero shear force (mid-span), \( L_v = L / 2 = 30 \text{ in.} \)

The critical shear stress, \( F_{cr} \), is the minimum of:

\[ F_{cr1} = \frac{1.60E}{\sqrt{\frac{L_v}{OD} \left( \frac{OD}{t} \right)^5}} = 633.4 \text{ ksi} \]

\[ F_{cr2} = \frac{0.78E}{\left( \frac{OD}{t} \right)^{3/2}} = 252.9 \text{ ksi} \]

\[ F_{cr3} = 0.6F_y = 30 \text{ ksi} \]

\[ F_{cr} = 30 \text{ ksi} \]

Nominal shear capacity:

\[ V_n = F_{cr} \frac{A_g}{2} = 223.8 \text{ kips} \]

The shear capacity:

The ultimate shear capacity (LRFD) = \[ \phi_c V_n = 0.9 \times 223.8 = 201.5 \text{ kips} \]

The allowable shear capacity (ASD) = \[ V_n / \Omega_c = 223.8 / 1.67 = 134.0 \text{ kips} \]

**Calculate Bending Capacity**

Bending capacity in plastic yielding:

\[ M_p = F_y \times Z = 50 \times 45.17 = 2,259 \text{ in} \times \text{kips} < 1.6F_y \times S = 1.6 (50) (33.76) = 2,701 \text{ in} \times \text{kips} \]

The bending capacity for flexural yielding:

The ultimate bending capacity (LRFD) = \[ \phi_b M_y = 0.9 \times 2,259 = 2,033 \text{ in} \times \text{kips} \]

The allowable bending capacity (ASD) = \[ M_y / \Omega_b = 2,259 / 1.67 = 1,352 \text{ in} \times \text{kips} \]

**Torsional Capacity**

The critical stress, \( F_{cr} \), is the larger of:

\[ F_{cr1} = \frac{1.23E}{\sqrt{\frac{L}{OD} \left( \frac{OD}{t} \right)^5}} = 344.3 \text{ ksi} \]

\[ F_{cr2} = \frac{1.23E}{\left( \frac{OD}{t} \right)^{3/2}} = 194.5 \text{ ksi} \]

But shall not exceed:
F_{cr3} = 0.6F_y = 30 ksi

F_{cr} = 30 ksi

Nominal torsional capacity:

T_n = F_{cr}C = 2,126 in kips

The torsional capacity:

The ultimate torsional capacity (LRFD) = \phi_c T_n = 0.9 \times 2,126 = 1,914 kips

The allowable torsional capacity (ASD) = T_n/\Omega_c = 2,126 / 1.67 = 1,273 kips

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:

\frac{P_r}{P_c} = \frac{10.23}{656.1} = 0.016 < 0.2 (LRFD)

\frac{P_r}{P_c} = \frac{10.23}{436.5} = 0.023 < 0.2 (ASD)

So use Eq. H1-1b for both methods:

\frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0.

\frac{0.016}{2} + \left( \frac{505.7}{2,033} + \frac{0}{2,033} \right) = 0.257 (LRFD)

\frac{0.023}{2} + \left( \frac{505.7}{1,352} + \frac{0}{1,352} \right) = 0.386 (ASD)

61. FINISH

*********** END OF THE STAAD.Pro RUN ***********

**** DATE= JAN 3,2022 TIME= 15: 9:23 ****
V. AISC 360-10 UPT Square Hollow Section

Verify the axial compression capacity, shear capacity, flexure capacity, torsional capacity, and interaction ratio of a user-provided hollow square section member per both the LRFD and ASD methods of the AISC 360-10 code.

Details

A 5' × 5' portal frame consists of W12x72 columns and a UPT SHS member for the beam. The section outer depth, \( D \), is 8" and the thickness, \( t \), is 0.30".
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concentrated torque of 0.75 in-kips at mid-span of the beam.

Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ F_y = 50 \text{ ksi} \]

**Validation**

**Design Forces**

The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 599.6 \text{ in-kips}, F_y = 67.5 \text{ kips} \)

**Section Properties**

- Inner depth, \( d = 8 - 2 \times 0.30 = 7.40 \text{ in.} \)
- Area, \( A_g = D^2 - d^2 = 9.24 \text{ in}^2 \)
- Shear area, \( A_w = 2D \times t_w = 4.80 \text{ in}^2 \)
- Moment of inertia, \( I = \frac{1}{12}(D^4 - d^4) = 91.45 \text{ in}^4 \)
- Elastic section modulus, \( S = \frac{I}{D/2} = \frac{91.45}{8/2} = 22.86 \text{ in}^3 \)
- Radius of gyration, \( r = \sqrt{\frac{I}{A_g}} = \sqrt{\frac{91.45}{9.24}} = 3.146 \text{ in} \)
- Plastic section modulus, \( Z = \frac{1}{6}(D^3 - d^3) = 26.69 \text{ in}^3 \)
- HSS Torsional constant, \( C = 2(B \times t_w)(D - t_w)t_w \times 4.5(4 \times \pi)t_w^3 = 35.47 \text{ in}^3 \)

**Section Classification**

- The design thickness, \( t = 0.93 \times t_w = 0.279 \text{ in.} \)
- The design depth, \( d = D - 3t = 7.163 \text{ in.} \)
Flange in compression
\[ \lambda = \frac{d}{T} = \frac{7.163}{0.279} = 25.67 \]
Per Table 4.1a Case 6, \( \lambda < \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{50}} = 33.72 \), therefore flanges are non-slender for compression. Similar for the web of the square section.

Flexure classification of flange:
Per Table 4.1b, Case 17, \( \lambda < \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{50}} = 26.97 \), therefore flange is compact for bending.

Flexure classification of web:
Per Table 4.1b, Case 19, \( \lambda < \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{50}} = 58.28 \), therefore web is compact for bending.

**Compression Capacity**

Effective slenderness ratio:
\[ \frac{k_x L_x}{r_x} = \frac{1.0(60)}{3.146} = 19.07 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

Elastic buckling stress:
\[ F_e = \frac{n^2 E}{(k_x L_x)^2} = \frac{n^2 \times 29,000}{(19.07)^2} = 787 \text{ ksi} \quad (\text{Eq. E3-4}) \]

Critical buckling stress:
\[ F_{cr} = 0.658 \left( \frac{F_y}{F_e} \right) F_y = 0.658 (0.064) 50 = 48.68 \text{ ksi} \quad (\text{Eq. E3-2}) \]

Nominal buckling strength:
\[ P_n = A_g \times F_{cr} = 9.24 \times 48.68 = 449.9 \text{ kips} \quad (\text{Eq. E3-1}) \]

The axial capacity:
- The ultimate compression capacity (LRFD) = \( \phi_c P_n = 0.9 \times 449.9 = 404.9 \text{ kips} \)
- The allowable compression capacity (ASD) = \( P_n / \Omega_c = 449.9 / 1.67 = 269.4 \text{ kips} \)

**Calculate Shear Capacity**
The nominal shear strength:
\[ V_n = 0.6 \times F_y \times A_w \times C_{v2} \quad (\text{Eq. G4-1}) \]

where
\[ C_{v2} = 1.0 \text{ per Section G2.2 with } h/t = 25.67 \text{ and } K_v = 5. \]
\[ V_n = 0.6 (50) (4.80) (1.0) = 144 \text{ kips} \]

The shear capacity:
- The ultimate shear capacity (LRFD) = \( \phi_v V_n = 0.9 \times 144 = 129.6 \text{ kips} \)
The allowable shear capacity (ASD) = $V_n/\Omega_v = 144 / 1.67 = 86.23$ kips

**Calculate Bending Capacity**

Bending capacity in plastic yielding (compact section):

$$M_p = F_y \times Z_x = 50 \times 26.69 = 1,335 \text{ in} \times \text{kips}$$

(Eq F7-1)

The bending capacity for flexural yielding about the Y axis:

The ultimate bending capacity (LRFD) = $\phi_b M_y = 0.9 \times 1,335 = 1,201 \text{ in} \times \text{kips}$

The allowable bending capacity (ASD) = $M_y/\Omega_b = 1,335 / 1.67 = 799.2 \text{ in} \times \text{kips}$

**Torsional Capacity**

$$\frac{h}{\tau} = 25.67 < 2.45 \sqrt{\frac{F_c}{F_y}} = 59.0$$

$F_{cr} = 0.6F_y = 30 \text{ ksi}$

Nominal torsional capacity:

$$T_n = F_{cr} \times C = 1,064 \text{ ksi}$$

The torsional capacity:

The ultimate torsional capacity (LRFD) = $\phi_T T_n = 0.9 \times 1,064 = 957.7 \text{ kips}$

The allowable torsional capacity (ASD) = $T_n/\Omega_T = 1,064 / 1.67 = 637.2 \text{ kips}$

**Interaction Ratio for Bending and Compression**

Check the interaction ratio for Load Case 1:

$$\frac{P_r}{P_c} = \frac{11.80}{404.9} = 0.029 < 0.2 \text{ (LRFD)}$$

$$\frac{P_r}{P_c} = \frac{11.80}{269.4} = 0.044 < 0.2 \text{ (ASD)}$$

So use Eq. H1-1b for both methods:

$$\frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0.$$

$$\frac{0.029}{2} + \left( \frac{599.7}{1,201} + \frac{0}{1,201} \right) = 0.514 \text{ (LRFD)}$$

$$\frac{0.044}{2} + \left( \frac{599.7}{799.2} + \frac{0}{799.2} \right) = 0.765 \text{ (ASD)}$$

**Results**

### STAAD.Pro Input

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\AISC 360-10 UPT Square Hollow Section.STD` is typically installed with the program.

The following [D1.A.6 Design Parameters](on page 1093) are used:

- The welded SHS member is specified using STP 2
- Shear lag factor, $U$ for tension rupture capacity is specified by SLF 0.8

The remaining parameters all use their default values.

STAAD.PRO CODE CHECKING - (AISC-360-10-ASD) v1.4a
V. AISC 360-10 UPT Pipe Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered I section member per both the LRFD and ASD methods of the AISC 360-10 code.

Details

A 5' × 5' portal frame consists of W12x72 columns and a UPT pipe member for the beam. The pipe outer diameter, \( D \), is 10" and the thickness, \( t \), is 0.25".
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concentrated torque of 0.75 in·kips at mid-span of the beam.

Material Properties

E = 29,000 ksi
Fy = 50 ksi

Validation

Design Forces
The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 599.6 \text{ in·kips} \), \( F_y = 67.5 \text{ kips} \)

**Section Properties**

- Inner diameter, \( d = 10 - 2 \times 0.25 = 9.5 \text{ in.} \)
- Area, \( A_g = \frac{\pi}{4} (D^2 - d^2) = 7.66 \text{ in}^2 \)
- Shear area, \( A_y = A_x = A_g / 2 = 3.83 \text{ in}^2 \)
- Moment of inertia, \( I_x = I_y = \frac{\pi}{64} (D^4 - d^4) = 91.05 \text{ in}^4 \)
- Elastic section modulus, \( S_{xx} = \frac{I_x}{D/2} = \frac{91.05}{10/2} = 18.21 \text{ in}^3 \)
- Radius of gyration, \( r_x = \sqrt{\frac{I_{xx}}{A_g}} = \sqrt{\frac{91.05}{7.66}} = 3.448 \text{ in} \)
- Plastic section modulus, \( Z_x = \frac{1}{6} (D^3 - d^3) = 23.77 \text{ in}^3 \)
- HSS Torsional constant, \( C = \frac{n}{2} (D - t)^2 t = 37.33 \text{ in}^3 \)

**Section Classification**

- Flange in compression:
  \[ \lambda = \frac{D}{t} = \frac{10}{0.25} = 40 \]
  Per Table 4.1a Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} = 0.11 \frac{29,000}{50} = 63.8 \), therefore flanges are non-slender for compression.

- Web in compression:
  Per Table 4.1a, Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} = 0.11 \frac{29,000}{50} = 63.8 \), therefore the web is non-slender for compression.

- Flexure classification:
  Per Table 4.1b, Case 20, \( \lambda < \lambda_p = 0.07 \frac{E}{F_y} = 0.07 \frac{29,000}{50} = 40.6 \), therefore flange is compact for bending.

**Compression Capacity**

- Effective slenderness ratio:
  \[ \frac{k_x L_x}{r_x} = \frac{1.060}{3.448} = 0.30 \]
  \[ \frac{k_x L_x}{r_x} = 17.40 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

- Elastic buckling stress:
  \[ F_e = \frac{n^2 E}{(k_x L_x/r_x)^2} = \frac{n^2 \times 29,000}{(17.40)^2} = 945 \text{ ksi} \]
  \[ \frac{F_y}{F_e} = \frac{50}{945} = 0.053 < 2.25 \]
Critical buckling stress:

\[ F_{cr} = 0.658 F_y \cdot F_e \cdot F_y = 0.658(0.053)^{50} = 48.91 \text{ ksi} \]  

(Eq. E3-2)

Nominal buckling strength:

\[ P_n = A_g \times F_{cr} = 7.66 \times 48.91 = 374.5 \text{ kips} \]  

(Eq. E3-1)

The axial capacity:

The ultimate compression capacity (LRFD) = \( \phi_c P_n = 0.9 \times 374.5 = 337.0 \text{ kips} \)

The allowable compression capacity (ASD) = \( P_n / \Omega_c = 374.5 / 1.67 = 224.3 \text{ kips} \)

Calculate Shear Capacity

Critical stress is the minimum of \( F_{cr1}, F_{cr2}, \) and \( F_{cr3} \):

\[ F_{cr1} = \frac{1.23E}{\sqrt{\frac{L}{D} \left( \frac{D}{t} \right)^{\frac{3}{4}}}} = 144.8 \text{ ksi} \]

\[ F_{cr2} = \frac{0.78E}{\left( \frac{D}{t} \right)^{\frac{3}{2}}} = 89.4 \text{ ksi} \]

\[ F_{cr3} = 0.6F_y = 30 \text{ ksi} \]

So, \( F_{cr} = 30 \text{ ksi} \).

The nominal shear strength:

\[ V_n = F_{cr} \times A_x = 30 \times 3.83 = 114.9 \text{ kips} \]

The axial capacity:

The ultimate shear capacity (LRFD) = \( \phi_v V_n = 0.9 \times 114.9 = 103.4 \text{ kips} \)

The allowable shear capacity (ASD) = \( V_n / \Omega_v = 114.9 / 1.67 = 68.78 \text{ kips} \)

Calculate Bending Capacity

Bending capacity in plastic yielding (compact section):

\[ M_y = F_y \times Z_x = 50 \times 23.77 = 1,189 \text{ in} \cdot \text{kips} \]  

(Eq F8-1)

The bending capacity for flexural yielding about the Y axis:

The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 1,189 = 1,070 \text{ in} \cdot \text{kips} \)

The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,189 / 1.67 = 711.7 \text{ in} \cdot \text{kips} \)

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:

\[ \frac{P_r}{P_c} = \frac{11.75}{337.0} = 0.034 < 0.2 \text{ (LRFD)} \]

\[ \frac{P_r}{P_c} = \frac{11.75}{224.3} = 0.052 < 0.2 \text{ (ASD)} \]
So use Eq. H1-1b for both methods: \[ \frac{P_r}{P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0. \]

\[
\frac{0.034}{2} + \left( \frac{599.6}{1,070} + \frac{0}{1,070} \right) = 0.578 \text{ (LRFD)}
\]

\[
\frac{0.052}{2} + \left( \frac{599.6}{711.7} + \frac{0}{711.7} \right) = 0.869 \text{ (ASD)}
\]

**Calculate Torsion Capacity**

Critical stress is the minimum of \( F_{cr1}, F_{cr2}, \) and \( F_{cr3} \). From shear calculations, \( F_{cr} = 30 \text{ ksi} \).

The nominal shear strength:

\[ T_n = F_{cr} \times C = 30 \times 37.33 = 1,120 \text{ in·kips} \]

The axial capacity:

The ultimate torsional capacity (LRFD) = \( \phi_T T_n = 0.9 \times 1,120 = 1,008 \text{ in·kips} \)

The allowable torsional capacity (ASD) = \( T_n / \Omega_T = 114.9 / 1.67 = 670.6 \text{ in·kips} \)

The following [D1A.6 Design Parameters](on page 1093) are used:

- The welded pipe member is specified using STP 2
- Shear lag factor, $U$ for tension rupture capacity is specified by SLF 0.8

The remaining parameters all use their default values.

### V. AISC 360-10 C WEAK AXIS SHEAR G.7

Verify the available shear strength along the weak axis of a singly symmetric section per the LRFD and ASD methods of the AISC 360-10 code.

**References**

**Related Links**

- *D1.A.5.4 Design for Shear* (on page 1087)
Details

From reference (2):

Verify the available shear strength and adequacy of a C9×20 ASTM A36 channel with end shears of 5.00 kips from dead load and 15.0 kips from live load in the weak direction.

Validation

Ultimate load:

\[ V_u = 1.2(5.0 \text{ kips}) + 1.6(15.0 \text{ kips}) = 30.0 \text{ kips} \]

Service load:

\[ V_a = 5.0 \text{ kips} + 15.0 \text{ kips} = 20.0 \text{ kips} \]

Area of the flanges for shear:

\[ A_w = 2b_tf = 2(2.65)(0.413) = 2.19 \text{ in}^2 \]

Section G2.1 of Reference 1 gives \( k_v = 1.2 \).

\[ \frac{b_f}{t_f} = \frac{2.65}{0.413} = 6.42 < 1.10 \sqrt{\frac{k_v E}{F_y}} = 1.10 \sqrt{\frac{1.2(29,000)}{36}} = 34.2 \]

Therefore, \( C_v = 1.0 \).

Nominal Shear Strength

\[ V_n = 0.6F_y A_w C_v = 0.6(36)(2.19)(1.0) = 47.3 \text{ kips} \quad \text{(Eq. G2-1)} \]

The available shear strength:

LRFD: \( \phi_v V_n = 0.90(47.3) = 42.6 \text{ kips} \)

ASD: \( V_n / \Omega_v = \frac{47.3}{1.67} = 28.3 \text{ kips} \)

V. AISC 360-10 W D.1
Verify the tensile strength a wide flange section per the LRFD and ASD methods of the AISD 360-10 code.

References

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Related Links
• D1.A.5.1 Axial Tension (on page 1085)

Details
From reference (2):
Select an 8-in. W-shape, ASTM A992, to carry a dead load of 30 kips and a live load of 90 kips in tension. The member is 25 ft long. Verify the member strength by both LRFD and ASD with the bolted end connection shown [in the reference]. Verify that the member satisfies the recommended slenderness limit. Assume that connection limit states do not govern.

See example D.1 in reference (2) for calculations.

• D1.A.5.1 Axial Tension (on page 1085)

Problem

From the reference:

Verify, by both ASD and LRFD, the tensile strength of an L4×4×1/2, ASTM A36 [...]. The member carries a dead load of 20 kips and a live load of 60 kips in tension. Calculate at what length this tension member would cease to satisfy the recommended slenderness limit. Assume that connection limit states do not govern.

Refer to the reference for calculations.

Comparison

Table 744: Comparison of results

<table>
<thead>
<tr>
<th>Result Type</th>
<th>Reference</th>
<th>STAAD.Pro</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tensile yielding $\phi_t P_n$ (kips) [LRFD]</td>
<td>122</td>
<td>122</td>
<td>none</td>
</tr>
<tr>
<td>Tensile rupture $\phi_t P_n$ (kips) [LRFD]</td>
<td>125</td>
<td>125</td>
<td>none</td>
</tr>
<tr>
<td>Tensile yielding $P_{n}/\Omega_t$ (kips) [ASD]</td>
<td>80.8</td>
<td>80.8</td>
<td>none</td>
</tr>
<tr>
<td>Result Type</td>
<td>Reference</td>
<td>STAAD.Pro</td>
<td>Difference</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------</td>
<td>-----------</td>
<td>------------</td>
</tr>
<tr>
<td>Tensile rupture $P_n/\Omega_s$ (kips) [ASD]</td>
<td>83.5</td>
<td>83.4</td>
<td>negligible</td>
</tr>
<tr>
<td>$L$ at which $\lambda = 300$ (ft)</td>
<td>19.4</td>
<td>19.4</td>
<td>none</td>
</tr>
</tbody>
</table>

To calculate the length at which the member would exceed the slenderness limit of 300: 

$$\frac{(6 \text{ in})}{(7.732)\times300} = 232.8 \text{ in} = 19.4 \text{ ft}$$

**STAAD Input**

The file `C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\AISC 360-10 - D-2.STD` is typically installed with the program.

**Tip:** You can copy and paste this content directly into a `.std` file to run in STAAD.Pro.

V. AISC 360-10 WT D.3

Verify the tensile strength a WT section per the LRFD and ASD methods of the AISD 360-10 code.

References

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Related Links

- D1.A.5.1 Axial Tension (on page 1085)

Details

From reference (2):

A WT6×20, ASTM A992 member has a length of 30 ft and carries a dead load of 40 kips and a live load of 120 kips in tension. The end connection is fillet welded on each side for 16 in. Verify the member tensile strength by both LRFD and ASD. Assume that the gusset plate and the weld are satisfactory.

See example D.3 in reference (2) for calculations.

STAAD SPACE -- PAGE NO.
V. AISC 360-10 HSST D.4

Verify the tensile strength of a rectangular HSS section per the LRFD and ASD methods of the AISC 360-10 code.

References

Related Links
• D1A.5.1 Axial Tension (on page 1085)

Details
From reference (2):

Verify the tensile strength of an HSS6x4x3/8, ASTM A500 Grade B, with a length of 30 ft. The member is carrying a dead load of 35 kips and a live load of 105 kips in tension. The end connection is a fillet welded 1/2-in.-thick single concentric gusset plate with a weld length of 16 in. Assume that the gusset plate and weld are satisfactory.

Validation

Ultimate load:

\[ P_u = 1.2(35 \text{ kips}) + 1.6(105 \text{ kips}) = 210 \text{ kips} \]

Service load:

\[ P_a = 35 \text{ kips} + 105 = 140 \text{ kips} \]

Tensile Yielding

LRFD: \[ \phi_t P_n = \phi_t A_g F_y = 0.9(6.18)(46) = 256 \text{ kips} \]

ASD: \[ P_n \left/ \frac{A_g F_y}{Q_c} \right. = \frac{(6.18)(46)}{1.67} = 170 \text{ kips} \]

Tensile Rupture
Determine the shear lag factor for the effective area:

\[ A_e = A_n U \]  (Eq. D3-1)

where

\[ A_n = \text{the net area; in this case allows for a } 1/16\text{-in gap in fit-up between the HSS and the gusset plate,} \]

\[ \bar{x} = B^2 + 2BH \quad \text{and} \quad U = \frac{(4.0)^2 + 2(4.0)(6.0)}{4(4.0 + 6.0)} = 1.60 \text{ in} \]

\[ A_e = 5.79(0.90) = 5.21 \text{ in}^2 \]

Nominal Tensile Rupture Strength

\[ P_n = F_u A_e = 58(5.21) = 302 \text{ kips} \]  (Eq D2-2)

The available tensile strength:

LRFD: \[ \phi_t P_n = 0.75(302) = 227 \text{ kips} \]

ASD: \[ \frac{P_n}{\Omega_t} = \frac{302}{2.00} = 151 \text{ kips} \]

Slenderness

\[ \frac{L}{r} = \frac{30 \times 12}{1.55} = 232 \]

Details

From reference (2):

Verify the tensile strength of an HSS6×0.500, ASTM A500 Grade B, with a length of 30 ft. The member carries a dead load of 40 kips and a live load of 120 kips in tension. Assume the end connection is a fillet welded 1/2-in.- thick single concentric gusset plate with a weld length of 16 in. Assume that the gusset plate and weld are satisfactory.

See example D.5 in reference (2) for calculations.

V. AISC 360-10 2L D.6

Verify the tensile strength a double angle section per the LRFD and ASD methods of the AISD 360-10 code.

References

Note: This reference is freely available for download from the AISC website at https://www.aisc.org/globalassets/aisc/university-programs/teaching-aids/first-semester-design-examples.pdf

Related Links

• D1.A.5.1 Axial Tension (on page 1085)

Details

From reference (2):

A 2L4×4×1/2 (3/8-in. separation), ASTM A36, has one line of (8) 3/4-in.-diameter bolts in standard holes and is 25 ft in length. The double angle is carrying a dead load of 40 kips and a live load of 120 kips in tension. Verify the member tensile strength. Assume that the gusset plate and bolts are satisfactory.

See example D.6 in reference (2) for calculations.

Results

V. AISC 360-05 Bending

To verify the flexural member strength in strong-axis bending of an I section for both LRFD and ASD methods per the AISC 360-05 code.

References

Related Links

• D1A.5.3 Flexural Design Strength (on page 1086)

Details

Verify the Flexural Member Strength in Strong-Axis Bending by both LRFD and ASD method with ASTM A992 W18X50 beam with a simple span of 35 feet. The nominal loads are a uniform dead load of 0.45 kip/ft and a uniform live load of 0.75 kip/ft. Assuming the beam is continuously braced.

Validation

ASTM A992: \( F_y = 50 \text{ ksi}, F_u = 65 \text{ ksi} \)

Calculate the required flexural strength:

LRFD

\[
\begin{align*}
    w_u &= 1.2 \times (0.450 \text{ kip/ft}) + 1.6 \times (0.750 \text{ kip/ft}) = 1.74 \text{ kip/ft} \\
    M_u &= \frac{1.74 \text{ kip/ft} \times (35.0 \text{ ft})^2}{8} = 266 \text{ kip-ft}
\end{align*}
\]

ASD

\[
    w_a = 0.450 \text{ kip/ft} + 0.750 \text{ kip/ft} = 1.20 \text{ kip/ft}
\]
\[ M_a = \frac{1.20 \text{kip}/\text{ft} \cdot (35.0 \text{ft}^2)}{8} = 184 \text{kip} \cdot \text{ft} \]

Per the User Note in section F-2 of ref 2 (p.16.1-47), the W18X50 section is compact. Since the beam is continuously braced and compact, only the yielding limit state applies.

**Tip:** Per Table 3-2 of ref. 2 (p.3-17), the W18X50 is *not* the most efficient shape for this individual beam. This example follows that given in ref 1. STAAD.Pro will select a lighter beam if the member selection command is used.

**LRFD**
\[ \phi_b M_n = \phi_b M_{px} = 0.9 \times (101 \text{ in}^3 \times 50 \text{ ksi})(1 \text{ ft} /12 \text{ in}) = 379 \text{ ft kip} > 266 \text{ ft kip} \]

**ASD**
\[ M_n / \Omega_b = M_{px} / \Omega_b = (101 \text{ in}^3 \times 50 \text{ ksi})(1 \text{ ft} /12 \text{ in}) / 1.67 = 252 \text{ ft kip} > 180 \text{ ft kip} \]

## V. AISC 360-05 Compression

Verify the axial compression capacity for a the y-y axis of an I section for both the LRFD and ASD methods per the AISC 360-05 code.

### References

1. Design Examples, Version 13.0, American Institute of Steel Construction, 2005, page E-4. Example E.1a

### Related Links

- D1.A.5.2 Axial Compression (on page 1086)

### Details

The column is 30 ft long, pinned top and bottom in both axis.

The section is an ASTM A992 (Fy = 50 ksi) W-shape column to carry an axial dead load of 140 kips and live load of 420 kips. The column is 30 feet long.

### Validation

Calculate the required strength.
LRFD:

\[ P_u = 1.2(140 \text{ kips}) + 1.6(420 \text{ kips}) = 840 \text{ kips} \]

ASD:

\[ P_a = 140 \text{ kips} + 420 \text{ kips} = 560 \text{ kips} \]

For a pinned-pinned condition, \( K = 1.0 \) (Table C-C2.2 of ref. 2). Because the unbraced length is equal about both \( x-x \) and \( y-y \) directions, \( y-y \) axis buckling governs.

Use Table 4-1 in ref 2 and select a W14x132 (\( K_{Ly} = 30 \text{ ft} \)). From this table:

\[ \phi_c P_n = 892 \text{ kips} > 840 \text{ kips} \]

\[ P_n/\Omega_c = 594 \text{ kips} > 560 \text{ kips} \]

**Results**

**V. AISC 360-05 Tension**

Verify the tensile yield strength and tensile rupture strength of an I section using both the LRFD and ASD methods per the AISC 360-05 code.

**Reference**

**Related Links**

- *D1A.5.1 Axial Tension* (on page 1085)

**Details**

Verify the member Tensile Yield strength and Tensile Rupture Strength by both LRFD and ASD with the bolted end connection of a I Section (W8X21) using the LRFD and ASD method

Steel Gr. ASTM A992.
The connection consists of 2 rows of 4-3/4"Ø bolts in each flange (16 bolts total) in standard holes. The holes are spaced evenly at 3" on center, with a 1-1/4" edge to center at the end of the flange in line with the tensile force.

Validation

ASTM A992: \( F_y = 50 \text{ ksi}, F_u = 65 \text{ ksi} \)

Assume a W8X21 section:

\[
\begin{align*}
A_g &= 6.16 \text{ in}^2 \\
b_f &= 5.27 \text{ in} \\
t_f &= 0.400 \text{ in} \\
d &= 8.28 \text{ in} \\
r_y &= 1.26 \text{ in} \\
y &= 0.831 \text{ in} \quad \text{(for a WT4X10.5)}
\end{align*}
\]

Calculate the required tensile strength.

LRFD

\[
P_u = 1.2(30 \text{ kips}) + 1.6(90 \text{ kips}) = 180 \text{ kips}
\]

ASD

\[
P_a = 30 \text{ kips} + 90 \text{ kips} = 120 \text{ kips}
\]

Check the tensile yield strength limit state using tabulated values per Table 5-1 in ref. 2:

\[
\phi_t P_n = 277 \text{ kips} > 180 \text{ kips}
\]

\[
P_n/\Omega_t = 184 \text{ kips} > 120 \text{ kips}
\]

Check the available tensile rupture strength at the end connection. The tabulated values are for \( A_e/A_g \geq 0.75 \). Verify this assumption is applicable.

Calculate U as the larger of the values from Table D3.1 case 2 or case 7 (ref. 2).

Case 2 - Check as two WT shapes:

\[
U = 1 - x/l = 1 - 0.831 \text{ in} / 9.0 \text{ in} = 0.908
\]

where

\[
\begin{align*}
l &= \text{length of the bolted connection} = 3 \times 3.0 \text{ in} = 9.0 \text{ in} \\
x &= \text{distance from the flange face to the plastic neutral axis. This is taken from Table 1-8 of ref. 2.}
\end{align*}
\]

Case 7

\[
b_f = 5.27 \text{ in} < 2/3d = 2/3(8.28 \text{ in}) = 5.52 \text{ in}; U = 0.85
\]

Use \( U = 0.908 \)

Calculate the net area at the bolted connection:

\[
A_n = A_g - 4(O_h + 1/16 \text{ in})t_f = 6.16 \text{ in}^2 - 4 \times (13/16 \text{ in} + 1/16 \text{ in})(0.400 \text{ in}) = 4.76 \text{ in}^2
\]

Calculate the effective area:

\[
A_e = A_n U = 4.76 \text{ in}^2 \times 0.908 = 4.32 \text{ in}^2
\]

\[
A_e/A_g = 4.32 \text{ in}^2 / 6.16 \text{ in}^2 = 0.701 < 0.75
\]
Therefore, the tabulated values for rupture do not apply. Calculate the rupture strength:

\[ P_n = F_u A_e = 65 \text{ ksi (4.32 in}^2) = 281 \text{ kips} \]

**LRFD**

\[ \phi_t P_n = 0.75(281 \text{ kips}) = 211 \text{ kips} > 180 \text{ kips} \]

**ASD**

\[ P_n/\Omega_t = 281 \text{ kips}/2.00 = 141 \text{ kips} > 120 \text{ kips} \]

---

### STAAD.Pro 5365 User Manual
A 2L4×4×2 (3/8-in. separation), ASTM A36, has one line of (8) ¾-in. diameter bolts in standard holes and is 25 ft in length. The double angle is carrying a dead load of 40 kips and a live load of 120 kips in tension. Verify the strength by both LRFD and ASD.

Validation
Refer to reference.

- User Manual
## Verification Examples

### V. AISC 360-05 Angle Section D-2

### References

Details

From reference (2):

Verify, by both ASD and LRFD, the strength of an L4×4×½, ASTM A36, with one line of (4) ¾ in. diameter bolts in standard holes. The member carries a dead load of 20 kips and a live load of 60 kips in tension. Calculate at what length this tension member would cease to satisfy the recommended slenderness limit.

Validation

Refer to reference.

### V. AISC 360-05 Built Up I E 12

#### References

#### Details

From reference (2):

Compute the available strength of a built-up compression member with a length of 14 ft. The ends are pinned. The outside flange is PL3/4×5, the inside flange is PL3/4×8, and the web is PL3/8×10½. Material is ASTM A572 Grade 50.

#### Validation

**Material Properties**

- $F_y = 50$ ksi
- $F_u = 65$ ksi

**Section Properties**

Built-up section properties (ignoring fillet welds):

\[
A_g = 8.0(0.75) + 10.5(0.375) + 5.0(0.75) = 13.7 \text{ in}^2
\]

\[
\bar{y} = \frac{\Sigma A_i y_i}{\Sigma A_i} = \frac{6.0(11.6) + 3.94(6.0) + 3.75(0.375)}{6.0 + 3.94 + 3.75} = 6.91 \text{ in}
\]

where $\bar{y}$ is measured from the bottom of the outside flange.

\[
I_x = \left[8.0(0.75)(4.72)^2 + \frac{8.0(0.75)^3}{12}\right] + \left[0.375(10.5)(0.910)^2 + \frac{0.375(10.5)^3}{12}\right] + \left[5.0(0.75)(6.54)^2 + \frac{5.0(0.75)^3}{12}\right] = \text{in}^4
\]

\[
I_y = \frac{0.75 \times 8.0^3}{12} + \frac{10.5 \times 0.375^3}{12} + \frac{0.75 \times 5.0^3}{12} = 39.9 \text{ in}^4
\]
Distance between flange centroids:

\[ h_0 = 12.0 - \frac{0.75}{2} - \frac{0.75}{2} = 11.3 \text{ in} \]

Due to symmetry about the y-axis, the shear center lies on the y-axis \((x_0 = 0)\). The distance from the centroid to the shear center can be calculated by finding the shear center from outside flange plus one-half the outside flange and then subtracting the centroid distance from that same reference point.

\[ \bar{y} = 0 + (2.55)^2 + \frac{344 + 39.9}{13.7} = 33.8 \text{ in}^2 \]

\[ R_0^2 = x_0^2 + y_0^2 + \frac{I_x + I_y}{A_g} = 1 - 0 + (2.55)^2 = 0.808 \]

Elastic Flexural Buckling Stress

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

\[ \frac{K_yL}{r_y} = \frac{1.0(14.0)(12)}{1.71} = 98.2 \]

\[ F_{ey} = \frac{n^2E}{KL \left( \frac{r_y^2}{2} \right)} = \frac{n^2(29,000)}{(98.2)^2} = 29.7 \text{ ksi} \] (Eq. E4-8)

\[ F_{ez} = \left[ \frac{n^2Ew}{(K_zL)^2} + GJ \left( \frac{1}{A_g} \right) \right] \left[ 1 - \frac{1}{11,200(2.01)} \right] \left( \frac{1}{13.7 \times 33.8} \right) = 66.2 \text{ ksi} \] (Eq. E4-9)

\[ F_e = \left( \frac{F_{ey} + F_{ez}}{2H} \right) \left[ 1 - \sqrt{1 - \frac{4F_{ey}F_{ez}H}{(F_{ey} + F_{ez})^2}} \right] = \left( \frac{29.7 + 66.2}{2 \times 0.808} \right) \left[ 1 - \sqrt{1 - \frac{4(29.7)(66.2)0.808}{(29.7 + 66.2)^2}} \right] = 26.4 \text{ ksi} \] (Eq. E4-5)

Nominal Compressive Strength

\[ \frac{F_y}{2.25} = \frac{50}{2.25} = 22.2 \text{ ksi} < 26.4 \text{ ksi} \]

\[ F_{cr} = \left( 0.658 \frac{F_y}{F_e} \right) F_y = \left[ 0.658 \frac{50}{(26.4)} \right] 50 = 22.6 \text{ ksi} \] (Eq E7-2)
\[ P_n = F_{cr} A_g = 22.6(13.7) = 310 \text{ kips} \]  
(Eq E7-1)

The available compressive strength:

LRFD: \( \phi c P_n = 0.90(310) = 279 \text{ kips} \)

ASD: \( P_n / \Omega_c = \frac{310}{1.67} = 186 \text{ kips} \)

V. AISC 360-05 Built up I E.2

References

Details
From reference (2):

Verify that a built-up, ASTM A572 grade 50, column with PL1 in. × 8 in. flanges and a PL1/4 in. × 15 in. web is sufficient to carry a dead load of 70 kips and live load of 210 kips in axial compression. The column length is 15 ft and the ends are pinned in both axes.

Validation
Ultimate load:

\[ P_u = 1.2(70 \text{ kips}) + 1.6(210 \text{ kips}) = 420 \text{ kips} \]

Service load:

\[ P_a = 70 \text{ kips} + 210 \text{ kips} = 280 \text{ kips} \]

Section Properties
Built-up section properties (ignoring fillet welds):

\[
A = 2(8.0)(1.0) + 15.0(0.25) = 19.8 \text{ in}^2
\]

\[
I_x = \Sigma A d^2 + \Sigma b h^3 12 = 2\left[8(8.0)^2 + \frac{8.0(1.0)^3}{12}\right] + \frac{0.25(15.0)^3}{12} = 1, 100 \text{ in}^4
\]

\[
I_y = 2\left(\frac{1.0 \times 8.0^3}{12}\right) + \frac{15.0 \times 0.25^3}{12} = 85.4 \text{ in}^4
\]

\[
r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{85.4}{19.8}} = 2.08 \text{ in}
\]

Elastic Flexural Buckling Stress
Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

\[
\frac{KL}{r_y} = \frac{1.0(15.0)(12)}{2.08} = 86.5
\]

\[
F_e = \frac{n^2 E}{(KL/r_y)^2} = \frac{n^2 29,000}{(86.5)^2} = 38.3 \text{ ksi} \quad \text{(Eq. E3-4)}
\]

Slenderness
Check for slender flanges and then determine the unstiffened element (flange) reduction factor.

\[
k_c = \frac{4}{\sqrt{h/t_w}} = \frac{4}{\sqrt{15.0/0.25}} = 0.516 \quad \text{(Table B4.1b note a)}
\]
0.35 < k < 0.76

Flange slenderness:

\[
\lambda = \frac{b}{t} = \frac{4.0}{1.0} = 4.0
\]

The limiting flange slenderness ratio, \(\lambda_r\):

\[
\lambda_r = 0.64 \sqrt{\frac{k}{c}} \frac{E}{F_y} = 0.64 \sqrt{\frac{0.516(29,000)}{50}} = 11.1 > \lambda
\]

(Table B4.1a, case 2)

Thus, the flanges are not slender and there is no reduction \((Q_s = 1.0)\).

Check for slender web and then determine the stiffened element (web) reduction factor.

Web slenderness:

\[
\lambda = \frac{h}{t} = \frac{15.0}{0.25} = 60.0
\]

The limiting web slenderness ratio, \(\lambda_r\):

\[
\lambda_r = 1.49 \sqrt{\frac{E}{F_y}} = 1.49 \sqrt{\frac{29,000}{50}} = 35.9 < \lambda
\]

(Table B4.1a, case 5)

Thus, the web is slender.

\[
Q_a = \frac{A_e}{A_g}
\]

(Eq. E7-16)

where

\[
A_e = \text{the effective area based on the reduced effective width, } b_e
\]

\[
b_e = 1.92t\sqrt{\frac{E}{F}} \left[ 1 - \frac{0.34}{(b/t)} \sqrt{\frac{E}{F}} \right] \leq b \quad \text{(Eq. E7-17)}
\]

\[
f = F_{cr} \text{ calculated based on } Q = 1.0
\]

\[
F_{cr} = Q(0.658 \frac{Q}{F_e}) F_y = 1.0 \left[ 0.658 \frac{1.0(50)}{(38.3)} \right] 50 = 29.0 \text{ ksi because}
\]

\[
\frac{KL}{r} = 86.5 < 4.71 \sqrt{\frac{E}{QF_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113
\]

\[
b_e = 1.92(0.25) \sqrt{\frac{29,000}{29.0} \left[ 1 - \frac{0.34}{(15/0.25)} \sqrt{\frac{29,000}{29.0}} \right]} = 12.5 < 15 \text{ in}
\]

\[
A_e = b_e t_w + 2b_{t} f = 12.5(0.25) + 2(8.0)(1.0) = 19.1 \text{ in}^2
\]

\[
Q_a = \frac{19.1}{19.8} = 0.965
\]

\[
Q = Q_s Q_a = 1.0 \times 0.965 = 0.965
\]

\[
\frac{KL}{r} = 86.5 < 4.71 \sqrt{\frac{E}{QF_y}} = 4.71 \sqrt{\frac{29,000}{0.965(50)}} = 113
\]

\[
F_{cr} = Q(0.658 \frac{Q}{F_e}) F_y = 0.965 \left[ 0.658 \frac{0.965(50)}{(38.3)} \right] 50 = 28.5 \text{ ksi}
\]

Nominal Compressive Strength

\[
P_n = F_{cr} A_g = 28.5(19.8) = 564 \text{ kips}
\]

(Eq E7-1)

The available compressive strength:
LRFD: $\phi_c P_n = 0.90(564) = 508 \text{ kips}$

ASD: $P_n / Q_c = \frac{564}{1.67} = 338 \text{ kips}$

### V. AISC 360-05 Built up I E.3

#### References

#### Details

From reference (2):

Determine if a built-up, ASTM A572 grade 50 column with PL3/8 in.×102 in. flanges and a PL1/4 in.×7 1/4 in. web has sufficient available strength to carry a dead load of 40 kips and a live load of 120 kips in axial compression. The column unbraced length is 15 ft in both axes and the ends are pinned.

#### Validation

Ultimate load:
\[ P_u = 1.2(40 \text{ kips}) + 1.6(120 \text{ kips}) = 240 \text{ kips} \]

Service load:
\[ P_a = 40 \text{ kips} + 120 \text{ kips} = 160 \text{ kips} \]

Section Properties

Built-up section properties (ignoring fillet welds):
\[ A_g = 2(10.5)(0.375) + 7.25(0.25) = 9.69 \text{ in}^2 \]
\[ I_x = \sum A d^2 + \frac{1}{2} h b^3 = 2\left[10.5 \times 0.375(3.81)^2 + \frac{10.5(0.25)^3}{12}\right] + \frac{0.25(7.25)^3}{12} = 122 \text{ in}^4 \]
\[ I_y = 2\left(\frac{0.375 \times 10.5^3}{12}\right) + \frac{7.25 \times 0.25^3}{12} = 72.4 \text{ in}^4 \]
\[ r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{72.4}{9.69}} = 2.73 \text{ in} \]

From the User Note in Section E4 of Reference 1:
\[ C_w = \frac{I_y h}{4} = \frac{72.4(7.63)^2}{4} = 1,050 \text{ in}^6 \]

From Eq. 3.4 in Reference 3:
\[ J = \sum \frac{b t^3}{3} = \frac{2(10.5)(0.375)^3 + 7.25(0.25)^3}{3} = 0.407 \text{ in}^4 \]

Slenderness

Check for slender web and then determine the stiffened element (web) reduction factor.

Web slenderness:
\[ \lambda = \frac{h}{t} = \frac{7.25}{0.25} = 29.0 \]

The limiting web slenderness ratio, \( \lambda_r \):
\[ \lambda_r = 1.49 \sqrt{\frac{E}{F_y}} = 1.49 \sqrt{\frac{29,000}{50}} = 35.9 > \lambda \]

Thus, the web is not slender and there is no reduction (i.e., \( Q_a 1.0 \))

Check for slender flanges and then determine the unstiffened element (flange) reduction factor.

\[ k_c = \frac{4}{\sqrt{h/t_w}} = \frac{4}{\sqrt{7.25/0.25}} = 0.743 \]

\( 0.35 < k_c < 0.76, OK. \)

Flange slenderness:
\[ \lambda = \frac{b}{t} = \frac{5.25}{0.375} = 14.0 \]

The limiting flange slenderness ratio, \( \lambda_r \):
\[ \lambda_r = 0.64 \sqrt{\frac{k_c E}{F_y}} = 0.64 \sqrt{\frac{0.743(29,000)}{50}} = 13.3 < \lambda \]
Thus, the flanges are slender.
\[
0.64 \sqrt{\frac{K_E}{F_y}} = 13.3 < \frac{b}{T} = 14.0 < 1.17 \sqrt{\frac{K_E}{F_y}} = 1.17 \sqrt{\frac{0.743(29, 000)}{50}} = 24.3
\]
\[
Q_s = 1.415 - 0.65\left(\frac{b}{T}\right)\sqrt{\frac{F_y}{K_E}} = 1.415 - 0.65(14.0)\sqrt{\frac{50}{0.743(29, 000)}} = 0.977
\]
\[
Q = Q_s Q_n = 0.977(1.0) = 0.977
\]

Elastic Flexural Buckling Stress

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.
\[
\frac{K_y L}{r_y} = \frac{1.0(15.0)(12)}{2.73} = 65.9
\]
\[
F_e = \frac{n^2 E}{(KL/r)^2} = \frac{n^2 29, 000}{(65.9)^2} = 65.9 \text{ ksi}
\]

Nominal Compressive Strength

\[
\frac{K L}{r} = 65.9 < 4.71 \sqrt{\frac{E}{Q F_y}} = 4.71 \sqrt{\frac{29, 000}{0.977(50)}} = 115
\]
\[
F_{cr} = Q\left(0.658 \frac{Q F_y}{F_e}\right) F_y = 0.977\left[0.658\frac{0.977(50)}{65.9}\right]50 = 35.8 \text{ ksi}
\]
\[
P_n = F_{cr} A_g = 35.8(6.69) = 347 \text{ kips}
\]

The available compressive strength:

LRFD: \( \phi_c P_n = 0.90(347) = 312 \text{ kips} \)

ASD: \( P_n / Q_c = \frac{347}{1.67} = 208 \text{ kips} \)

References

Details
From reference (2):

Select an ASTM A36 channel to serve as a roof edge beam with a simple span of 25 ft. Limit the live load deflection to L/360. The nominal loads are a uniform dead load of 0.23 kip/ft and a uniform live load of 0.69 kip/ft. The beam is continuously braced.

Validation
Ultimate moment:

\[ w_u = 1.2(0.23 \text{ k/ft}) + 1.6(0.69 \text{ k/ft}) = 1.38 \text{ k/ft} \]

\[ M_u = \frac{1.38(25)^2}{8} = 108 \text{ ft-k} \]

Service moment:
\[ w_a = 0.23 \text{ k/ft} + 0.69 \text{ k/ft} = 0.92 \text{ k/ft} \]

\[ M_a = \frac{0.92(25)^2}{8} = 71.9 \text{ ft-k} \]

Try a C15×33.9, which has a plastic section modulus, \( Z_x = 50.8 \text{ in}^3 \).

All ASTM A36 grade C-shapes are compact. The member is continuously braced, so therefore the yielding limit state governs.

\[ M_n = M_p = F_y \times Z_x = 36 \times 50.8 = 1,830 \text{ in-k} = 152 \text{ ft-k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(152) = 137 \text{ ft-k} \)

ASD: \( M_n / \Omega_b = \frac{152}{1.67} = 91.0 \text{ ft-k} \)

**Check for Bending-Yielding**
V. AISC 360-05 C LTB Test F.2-2

References

Details
From reference (2):

Check the C15×33.9 beam selected in V. AISC 360-05 C Flex Mem F.2-1 (on page 5401), assuming it is braced at the ends and the fifth points rather than continuously braced.

Validation
Ultimate moment:

\[ w_u = 1.2(0.23 \text{ k/ft}) + 1.6(0.69 \text{ k/ft}) = 1.38 \text{ k/ft} \]
\[ M_u = \frac{1.38(25)^2}{8} = 108 \text{ ft-k} \]

Service moment:
\[ w_a = 0.23 \text{ k/ft} + 0.69 \text{ k/ft} = 0.92 \text{ k/ft} \]
\[ M_a = \frac{0.92(25)^2}{8} = 71.9 \text{ ft-k} \]

The unbraced length, \( L_b = 5 \text{ ft} \).
Try a C15×33.9, which has a plastic section modulus, \( Z_x = 50.8 \text{ in}^3 \).
The lateral-torsional buckling modification factor, \( C_b = 1.0 \) for the center span of this bracing & loading condition.

\[ \begin{align*}
L_p &= 1.76r_y\sqrt{\frac{E}{F_y}} = 1.76(0.901)\sqrt{\frac{29,000}{36}(\frac{1}{12})} = 3.75 \text{ ft} \\
L_r &= \pi r t_s E^{0.7} = \pi (1.13)\sqrt{\frac{29,000}{0.7 \times 36}(\frac{1}{12})} = 10.0 \text{ ft}
\end{align*} \]  

\((F2-5)\) \((F2-6)\)

**Note:** This is the simplified, conservative calculation for \( L_r \) per the User Note used to verify that the section is in the plastic-elastic range. The reference uses the more exact calculation but the resulting flexural strength values are essentially equal.

\[ L_p < L_b \leq L_r \]

All ASTM A36 grade C-shapes are compact.

The nominal flexural strength for the flexural yielding limit state is:
\[ M_n = M_p = F_y \times Z_x = 36 \times 50.8 = 1,830 \text{ in-k} = 152 \text{ ft-k} \]

The nominal flexural strength for the lateral-torsional buckling limit state is:
\[ M_n = C_b \left[ M_p - (M_p - 0.7F_yS_x) \left( \frac{L_b - L_p}{L_r - L_p} \right) \right] \]
\[ = 1.0 \left[ 1, 830 - (1, 830 - 0.7 \times 36 \times 42)(\frac{5 - 3.75}{10 - 3.75}) \left( \frac{1}{12} \right) \right] = 145 \text{ ft-k} \]

The available flexural strength:
LRFD: \( \phi \omega M_n = 0.90(145) = 131 \text{ ft-k} \)
ASD: \( M_n / \Omega_b \leq 131 \left| 1.67 \right| = 86.8 \text{ ft-k} \)

V. AISC 360-05 C Strong Axis Shear G.2

References

Details
From reference (2):

Verify the shear strength of a C15×33.9 channel with end shears of 17.5 kips from dead load and 52.5 kips from live load.

Validation
Refer to reference.

Details

From reference (2):

Verify the strength of a C9×20 ASTM A36 channel with end shears of 5 kips from dead load and 15 kips from live load in the weak direction.

Validation

Ultimate load:

\[ V_u = 1.2(5.0 \text{kips}) + 1.6(15.0 \text{kips}) = 30.0 \text{kips} \]

Service load:

\[ V_a = 5.0 \text{kips} + 15.0 \text{kips} = 20.0 \text{kips} \]

Area of the flanges for shear:

\[ A_w = 2b_tf = 2(2.65)(0.413) = 2.19 \text{in}^2 \]

Section G2.1 of Reference 1 gives \( k_v = 1.2 \).

Therefore, \( C_v = 1.0 \).

Nominal Shear Strength

\[ V_n = 0.6F_yA_wC_v = 0.6(36)(2.19)(1.0) = 47.3 \text{kips} \]  
(Eq. G2-1)

The available shear strength:

LRFD: \( \phi_v V_n = 0.90(47.3) = 42.6 \text{kips} \)

ASD: \( V_n / \Omega_v = \left| \frac{47.3}{1.67} \right| = 28.3 \text{kips} \)

V. AISC 360-05 Double L E.5

References

Details

From reference (2):

Verify the strength of a 2L4×3 1/2×3/8 LLBB (3/4-in. separation) strut with a length of 8 ft and pinned ends carrying an axial dead load of 20 kips and live load of 60 kips. Also, calculate the required number of fully tightened or welded intermediate connectors required.

Validation

Refer to reference.

References

Details
From reference (2):

Determine if a 2L5×3×1/4 LLBB (3/4-in. separation) strut with a length of 8 ft and pinned ends has sufficient available strength to support a dead load of 10 kips and live load of 30 kips in axial compression. Also, calculate the required number of fully tightened or welded intermediate connectors.

Validation
Ultimate load:

\[ P_u = 1.2(10 \text{ kips}) + 1.6(30 \text{ kips}) = 60 \text{ kips} \]

Service load:

\[ P_a = 10 \text{ kips} + 30 \text{ kips} = 40 \text{ kips} \]

Per Table C-A-7.1 in Reference 1, \( K = 1.0 \) for pinned-pinned columns. Since the unbraced length is the same both directions, by inspection the y-y axis governs.

Slenderness

\[ \lambda = \frac{b}{t} = \frac{5.0}{0.25} = 20.0 \]

The limiting slenderness ratio, \( \lambda_r \):

\[ \lambda_r = 0.45 \sqrt{\frac{E}{F_y}} = 0.45 \sqrt{\frac{29,000}{36}} = 12.8 < \lambda \] (Table B4.1a, case 3)

Thus, the outstanding legs are slender.

Check for slender web and then determine the stiffened element (web) reduction factor.

\[ 0.45 \sqrt{\frac{E}{F_y}} = 12.8 < \frac{b}{t} = 20.0 < 0.91 \sqrt{\frac{E}{F_y}} = 0.91 \sqrt{\frac{29,000}{36}} = 25.8 \] (Eq. E7-11)

\[ Q_s = 1.34 - 0.76 \left( \frac{b}{t} \right) \sqrt{\frac{F_y}{E}} = 1.34 - 0.76(20.0) \sqrt{\frac{36}{29,000}} = 0.804 \]

\[ Q = Q_a Q_a = 0.804(1.0) = 0.804 \]

\[ F_{cr} = Q \left( 0.658 \frac{Q F_y}{F_y} \right) F_y \]

where
\[
F_e = \left( \frac{F_{ey} + F_{ez}}{2H} \right) \left[ 1 - \sqrt{1 - \frac{4F_{ey}F_{ez}H}{(F_{ey} + F_{ez})^2}} \right] \quad (\text{Eq E4-5})
\]

\[
K_i = 0.5 \text{ for angles back-to-back}
\]

\[
r_i = r_z = 0.652 \text{ in}; \text{ the radius of gyration for a single angle}
\]

\[
a = 32 \text{ in spacing between connectors (using the bolts at 1/3 points from Reference 2)}
\]

\[
\left( \frac{K_y L}{r_y m} \right) = \frac{\sqrt{\left( \frac{K L}{r} \right)^2 + \left( \frac{K a}{r_i} \right)^2}}{m} = \frac{\sqrt{1.0 \times 96^2 + (0.5 \times 32 \times 0.652)^2}}{76.3} = 76.3 \text{ for}
\]

\[
a = \frac{32 \text{ in}}{0.652 \text{ in}} = 49.1 > 40
\]

\[
F_{cy} = \frac{\pi^2 E}{6 \left( \frac{K_y L}{r_y m} \right)^2} = \frac{\pi^2 (29,000)}{(76.3)^2} = 49.2 \text{ ksi}
\]

\[
F_{ez} = \frac{G J}{A_g \bar{r}_0^2} = \frac{11,200 \times 0.04328 \times 2 \text{ angles}}{3.88 (2.59)^2} = 37.7 \text{ ksi}
\]

Thus, \( \frac{49.2 + 37.7}{2 \times 0.657} \left[ 1 - \sqrt{1 - \frac{4(49.2)(37.7)(0.657)}{(49.2 + 37.7)^2}} \right] = 26.8 \text{ ksi} \)

**Nominal Compressive Strength**

\[
\frac{Q F_y}{225} = \frac{0.804(36)}{225} = 12.9 \text{ ksi} < 26.8 \text{ ksi}
\]

\[
F_{cr} = Q \left( 0.658 \frac{Q F_y}{F_y} \right) F_y = 0.804 \left[ 0.658 \frac{0.804(36)}{26.8} \right] 36 = 18.4 \text{ ksi} \quad (\text{Eq E7-2})
\]

\[
P_n = F_{cr} A_g = 18.4(3.88) = 71.4 \text{ kips} \quad (\text{Eq E7-1})
\]

The available compressive strength:

LRFD: \( \phi_c P_n = 0.90(71.4) = 64.3 \text{ kips} \)

ASD: \( P_n / \Omega_c = \frac{71.4}{1.67} = 42.8 \text{ kips} \)

V. AISC 360-05 F.1-3 LTB I Section

References

Details
From reference (2):

Verify the strength of the W18×50 beam selected in Example F.1-1a if the beam is braced at the ends and center point rather than continuously braced.

From Example F1-1a (also found in Reference (1)):

Select an ASTM A992 W-shape beam with a simple span of 35 feet. Limit the member to a maximum nominal depth of 18 in. Limit the live load deflection to L/360. The nominal loads are a uniform dead load of 0.45 kip/ft and a uniform live load of 0.75 kip/ft.

Validation
Refer to reference.

References

Details
From reference (2):

An HSS6.000×0.500, ASTM A500 grade B, has a length of 30 ft. The member carries a dead load of 40 kips and a live load of 120 kips in tension. Assume the end connection is a fillet welded 1/2 in. thick single concentric gusset plate that has a length of 16 in. Verify the strength by both LRFD and ASD.

Validation
Refer to reference.

Intermediate Fcr | Tn
V. AISC 360-05 HSSP Shear Capacity G.5

References

Details
From reference (2):

Verify the shear strength of a round HSS16.000×0.375 ASTM A500 grade B member spanning 32 feet with end shears of 30 kips from dead load and 90 kips from live load.

Validation
Ultimate load:

\[ V_u = 1.2(30.0 \text{ kips}) + 1.6(90.0 \text{ kips}) = 180 \text{ kips} \]

Service load:

\[ V_a = 30.0 \text{ kips} + 90.0 \text{ kips} = 120 \text{ kips} \]
The maximum permitted value is $F_{cr} \leq 0.6F_y = 0.6(42) = 25.2\text{ ksi}$ (governs).

Nominal Shear Strength

$$V_n = F_{cr}A_g/2 = (25.2)(17.2)/2 = 217\text{ kips}$$  \hspace{1cm} \text{(Eq. G2-1)}

The available shear strength:

LRFD: $\phi_v V_n = 0.90(217) = 195\text{ kips}$

ASD: $V_n/\Omega_v = 217/1.67 = 130\text{ kips}$

ALL UNITS ARE - KIP  INCH (UNLESS OTHERWISE Noted)

---
V. AISC 360-05 HSSP Torsional Strength H.5B

References

Details
From reference (2):

Determine the available torsional strength of an ASTM A500 Gr. B HSS5.000×0.250 that is 14 ft long.

Validation
Critical Stress
The maximum permitted value is \( F_{cr} \leq 0.6 F_y = 0.6(42) = 25.2 \text{ ksi} \) (governs).

**Nominal Torsional Strength**

\[
T_n = F_{cr} C = 25.2(7.95) = 200 \text{ in} \cdot \text{k}
\]  

(Eq. G2-1)

The available shear strength:

LRFD: \( \phi_T T_n = 0.90(200) = 180 \text{ in} \cdot \text{k} \)

ASD: \( T_n / \Omega_T = \frac{200}{1.67} = 120 \text{ in} \cdot \text{k} \)

### V. AISC 360-05 HSST Compact Flange F.6

#### References

#### Details

From reference (2):

```
Select a square ASTM A500 Gr. B HSS beam to span 7.5 feet. The nominal loads are a uniform dead load of 0.145 kip/ft and a uniform live load of 0.435 kip/ft. Limit the live load deflection to L/240. Assume the beam is continuously braced.
```

#### Validation

Ultimate moment:

\[
w_u = 1.2(0.145 \text{ k/ft}) + 1.6(0.435 \text{ k/ft}) = 0.87 \text{ k/ft}
\]

\[
M_u = \frac{0.87(7.5)^2}{8} = 6.12 \text{ ft·k}
\]
Service moment:

\[ w_a = 0.145 \text{ k/ft} + 0.435 \text{ k/ft} = 0.580 \text{ k/ft} \]

\[ M_a = \frac{0.58(7.5)^2}{8} = 4.08 \text{ ft·k} \]

Calculate the minimum required moment of inertia:

\[ \Delta_{\text{max}} = \frac{L}{240} = \frac{7.50(12)}{240} = 0.375 \text{ in.} \]

\[ I_{\text{req}} = \frac{5wL^4}{384E \Delta_{\text{max}}} = \frac{5(0.435)(7.5)^4 (12)^3}{384(29,000)(0.375)} = 2.85 \text{ in.}^4 \]  
(Ref. 1, Table 3-23, Diagram 1)

Try a HSS 3×3×1/4, which has a plastic section modulus, \( I_x = 3.02 \text{ in}^4, Z_x = 2.48 \text{ in}^3 \).

The yield strength, \( F_y = 46 \text{ ksi} \)

Flange compactness: \( \lambda = b/t = 9.88 \)

Determine the compact flange ratio limit from Table B4.1b: \( \lambda_p = 1.12 \sqrt{\frac{F_y}{F_y}} = 1.12 \sqrt{\frac{29,000}{46}} = 28.1 > \lambda \)  
(Compact)

\[ M_n = M_p = F_y \times Z_x = 46 \times 2.48 = 114.1 \text{ in·k} = 9.51 \text{ ft·k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(9.51) = 8.56 \text{ ft·k} \)

ASD: \( M_n / \Omega_b = 9.51 / 1.67 = 5.69 \text{ ft·k} \)

V. AISC 360-05 HSST D.4

References
**Details**

From reference (2):

Verify, by LRFD and ASD, the strength of an HSS6×4×3/8, ASTM A500 grade B, with a length of 30 ft. The member is carrying a dead load of 35 kips and a live load of 105 kips in tension. Assume the end connection is fillet welded to a 1/2 in. thick single concentric gusset plate and has a length of 16 in.

**Validation**

Ultimate load:

\[ P_u = 1.2(35 \text{ kips}) + 1.6(105 \text{ kips}) = 210 \text{ kips} \]

Service load:

\[ P_a = 35 \text{ kips} + 105 = 140 \text{ kips} \]

**Tensile Yielding**

LRFD: \( \phi_t P_n = \phi_t A_n F_y = 0.9(6.18)(46) = 256 \text{ kips} \)

ASD: \( P_n/Q_c = \frac{A_n F_y}{2} = \frac{6.18(46)}{1.67} = 170 \text{ kips} \)

**Tensile Rupture**

Determine the shear lag factor for the effective area:

\[ A_e = A_n U \quad \text{(Eq. D3-1)} \]

where

\[ A_n = \text{the net area; in this case allows for a 1/16-in gap in fit-up between the HSS and the gusset plate,} \]

\[ = A_n - 2(t_p + 1/16) t = 6.18 - 2(0.5 + 1/16)0.349 = 5.79 \text{ in}^2 \]

\[ \bar{x} = \frac{B^2 + 2BH}{4(B + H)} = \frac{(4.0)^2 + 2(4.0)(6.0)}{4(4.0 + 6.0)} = 1.60 \text{ in} \]

\[ U = 1 - \frac{\bar{x}}{t} = 1 - \frac{1.60}{16.0} = 0.90 \]

\[ A_e = 5.79(0.90) = 5.21 \text{ in}^2 \]

**Nominal Tensile Rupture Strength**

\[ P_n = F_u A_e = 58(5.21) = 302 \text{ kips} \quad \text{(Eq D2-2)} \]

The available tensile strength:

LRFD: \( \phi_t P_n = 0.75(302) = 227 \text{ kips} \)

ASD: \( P_n/Q_t = \left| \frac{302}{2.00} \right| = 151 \text{ kips} \)

**Slenderness**

\[ \frac{L}{r} = \frac{30 \times 12}{1.55} = 232 \]

Intermediate Fcr Tn
### V. AISC 360-05 HSST NonCompact Flange F.7

**References**

**Details**

From reference (2):

Select a rectangular ASTM A500 Gr. B HSS beam with a span of 21 ft. The nominal loads include a uniform dead load of 0.15 kip/ft and a uniform live load of 0.40 kip/ft. Limit the live load deflection to L/240. Assume the beam is braced at the end points only.

**Validation**

Ultimate moment:

\[
w_u = 1.2(0.15 \text{ k/ft}) + 1.6(0.4 \text{ k/ft}) = 0.82 \text{ k/ft}
\]

\[
M_u = \frac{0.82(21)^2}{8} = 45.2 \text{ ft-k}
\]
\( w_a = 0.15 \text{k/ft} + 0.4 \text{k/ft} = 0.55 \text{k/ft} \)

\( M_a = \frac{0.55(21)^2}{8} = 30.3 \text{ ft-k} \)

Try a HSS 10\( \times \)6\( \times \)3/16, which has a plastic section modulus, \( Z_x = 18.0 \text{ in}^3 \) and a section modulus, \( S_x = 14.9 \text{ in}^3 \).

Flange compactness: \( \lambda = b/t = 31.5 \)

Determine the compact and slender flange ratio limits from Table B4.1b:

\( \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{46}} = 28.1 \)

\( \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{46}} = 35.2 \)

Thus, the section has a non-compact flange.

Web compactness: \( \lambda = h/t = 54.5 \)

\( \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{46}} = 60.8 > \lambda \)

Thus, the section has a compact web.

\( M_p = F_y \times Z_x = 46 \times 18.0 = 828 \text{ in-k} = 69.0 \text{ ft-k} \)

\( M_n = M_p - (M_p - F_y S) \left( 3.57 \frac{b}{t} \frac{F_y}{E} \cdot 4.0 \right) \)

\smaller{(F7-2)}

\[ = 828 - (828 - 0.7 \times 46 \times 14.9) \left( 3.57 \times 31.5 \sqrt{\frac{46}{29,000}} \cdot 4.0 \right) = 760 \text{ in-k} = 63.3 \text{ ft-k} \]

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(63.3) = 57.0 \text{ ft-k} \)

ASD: \( M_n / \Omega_b = \frac{63.3}{1.67} = 37.9 \text{ ft-k} \)

**Verification Examples**

**V.09 Steel Design**

**STAAD.Pro 5484 User Manual**
V. AISC 360-05 HSST Shear Capacity G.4

References

Details
From reference (2):

Verify the shear strength of a HSS6×4×3/8 ASTM A500 grade B member with end shears of 11 kips from dead load and 33 kips from live load. The beam is oriented with the shear parallel to the 6 in. dimension.

Validation

Ultimate load:

\[ V_u = 1.2(11.0 \text{ kips}) + 1.6(33.0 \text{ kips}) = 66.0 \text{ kips} \]

Service load:

\[ V_a = 11.0 \text{ kips} + 33.0 \text{ kips} = 44.0 \text{ kips} \]

Area of the web for shear:

**Note:** The corner radius is taken as 1.5× the design wall thickness per Section B4.1b of Reference 1.

\[
h = H - 3t = 6.0 - 3\times 0.349 = 4.95 \text{ in}
\]

Section G5 of Reference 1 gives \( k_v = 5 \).

\[
A_w = 2ht = 2(4.95)(0.349) = 3.46 \text{ in}^2
\]

\[
\frac{h}{t_w} = \frac{4.95}{0.349} = 14.2 < 1.10\sqrt{\frac{k_v E}{F_y}} = 1.10\sqrt{\frac{529,000}{46}} = 61.8
\]

Therefore, \( C_v = 1.0 \).

Nominal Shear Strength

\[
V_n = 0.6F_y A_w C_v = 0.6(46)(3.46)(1.0) = 95.5 \text{ kips}
\]  \hspace{1cm} (Eq. G2-1)

The available shear strength:

LRFD: \( \phi_v V_n = 0.90(95.5) = 86.0 \text{ kips} \)

ASD: \[ V_n / Q_v = \frac{95.5}{1.67} = 57.2 \text{ kips} \]

V. AISC 360-05 HSST Slender Flange F.8

References

Details
From reference (2):

Verify the strength of an ASTM A500 Gr. B HSS8×8×xx with a span of 21 ft. The nominal loads are a dead load of 0.125 kip/ft and a live load of 0.375 kip/ft. Limit the live load deflection to L 240.

Validation
Ultimate moment:

\[ w_u = 1.2(0.125 \text{ kip/ft}) + 1.6(0.375 \text{ kip/ft}) = 0.75 \text{ kip/ft} \]

\[ M_u = \frac{0.75(21)^2}{8} = 41.3 \text{ ft k} \]

Service moment:

\[ w_a = 0.125 \text{ kip/ft} + 0.375 \text{ kip/ft} = 0.50 \text{ kip/ft} \]

\[ M_a = \frac{0.5(21)^2}{8} = 27.6 \text{ ft k} \]

Try a HSS 8×8×3/16, which has a plastic section modulus, \( Z_x = 15.7 \text{ in}^3 \) and a section modulus, \( S_x = 13.6 \text{ in}^3 \). The yield strength, \( F_y = 46 \text{ ksi} \)

Flange compactness: \( \lambda = b/t = 43.0 \)

Determine the slender flange ratio limit from Table B4.1b: \( \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{46}} = 35.2 < \lambda \) (Slender)

Web compactness: \( \lambda = h/t = 43.0 \)

\[ \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{46}} = 60.8 > \lambda \]

Thus, the section has a compact web.
\[ M_n = F_y \times S_e \]  
\text{(F7-3)}

where

\[ S_e = \text{the effective section modulus determined with the effective compression flange taken as } b_e \]

\[ b_e = 1.93t_f \sqrt{\frac{E}{F_y}} \left[ 1 - 0.38 \left( \frac{E}{F_y} \right) \right] = 1.93 \times 0.174 \sqrt{\frac{29,000}{46}} \left[ 1 - 0.38 \left( \frac{29,000}{46} \right) \right] = 6.53 \text{ in} \]

The width of the compression flange between the corners (assumed to be 1.5t) is:

\[ b = 8 - 2 \times 1.5 \times t = 8 - 3(0.174) = 7.48 \text{ in} > 6.53 \text{ in} \]

Thus, the ineffective width of the compression flange is:

\[ b - b_e = 7.48 - 6.53 = 0.95 \text{ in} \]

Subtract this contribution of this ineffective flange area from the gross moment of inertia to approximate the effective moment of inertia:

\[ I_{\text{eff}} \approx 54.4 - 2 \left( 0.95(0.174) \right)^3 + 0.95(0.174)(3.91)^3 = 49.3 \text{ in}^4 \]

\[ S_e = \frac{I_{\text{eff}}}{d/2} = \frac{49.3}{8.0/2} = 12.3 \text{ in}^3 \]

\[ M_n = 46 \times 12.3 = 566 \text{ in-k} = 47.2 \text{ ft-k} \]

The available flexural strength:

\[ \text{LRFD: } \phi_b M_n = 0.90(47.2) = 42.5 \text{ ft-k} \]

\[ \text{ASD: } M_n / \Omega_b = \frac{47.2}{1.67} = 28.3 \text{ ft-k} \]

STAAD.PRO CODE CHECKING - (AISC-360-05-ASD) v3.3a

ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE NOTED)
V. AISC 360-05 HSST Torsional Strength H.5A

References

Details
From reference (2):

Determine the available torsional strength of an ASTM A500 Gr. B HSS6×4×1/4.

Validation

\[ h/t > b/t \text{, so } h/t \text{ governs.} \]

\[ \frac{h}{t} = 22.8 < 2.45 \sqrt{\frac{E}{F_y}} = 2.45 \sqrt{\frac{29,000}{46}} = 61.5 \]

\[ F_{cr} = 0.6F_y = 0.6(46) = 27.6 \text{ ksi} \quad \text{(Eq. H3-3)} \]

Nominal Torsional Strength

\[ T_n = F_{cr}C = 27.6(10.1) = 279 \text{ in} \cdot \text{k} \quad \text{(Eq. G2-1)} \]

The available shear strength:

LRFD: \( \phi_T T_n = 0.90(279) = 251 \text{ in} \cdot \text{k} \)

ASD: \( T_n / \Omega_T = \frac{279}{1.67} = 167 \text{ in} \cdot \text{k} \)

V. AISC 360-05 I Minor Axis Bending F.5

References

Details

From reference (2):

Select an ASTM A992 W-shape beam loaded in its minor axis with a simple span of 15 ft. The nominal loads are a total uniform dead load of 0.667 kip/ft and a uniform live load of 2 kip/ft. Limit the live load deflection to L/240. Assume the beam is braced at the ends only.

Validation

Refer to reference.

V. AISC 360-05 L Shear Capacity G.3

**References**

**Details**

From reference (2):
Verify the shear strength of a 5×3×1/4 (LLV) ASTM A36 angle with end shears of 3.5 kips from dead load and 10.5 kips from live load.

Validation

Ultimate load:

\[ V_u = 1.2(3.50 \text{ kips}) + 1.6(10.5 \text{ kips}) = 21.0 \text{ kips} \]

Service load:

\[ V_a = 3.50 \text{ kips} + 10.5 \text{ kips} = 14.0 \text{ kips} \]

Area of the web for shear:

\[ A_w = bt = 5.0(0.25) = 1.25 \text{ in}^2 \]

Section G4 of Reference 1 gives \( k_v = 1.2 \).

Therefore, \( C_v = 1.0 \).

Nominal Shear Strength

\[ V_n = 0.6F_yA_wC_v = 0.6(36)(1.25)(1.0) = 27.0 \text{ kips} \]

(Eq. G2-1)

The available shear strength:

LRFD: \( \phi_V V_n = 0.90(27.0) = 24.3 \text{ kips} \)

ASD: \( V_n / \Omega_V = \frac{27.0}{1.67} = 16.2 \text{ kips} \)

All units are - KIP INCH (Unless otherwise noted)

---

STAAD Space
Verification Examples
V.09 Steel Design

V. AISC 360-05 Pipe F.9

References

Details
From reference (2):

Select an ASTM A53 grade B Pipe shape with a simple span of 16 ft. The nominal loads are a total uniform dead load of 0.32 kip/ft and a uniform live load of 0.96 kip/ft. Assume there is no deflection limit for this beam. The beam is braced only at the ends.

Validation
Ultimate moment:

\[ w_u = 1.2(0.32 \text{ k/ft}) + 1.6(0.96 \text{ k/ft}) = 1.92 \text{ k/ft} \]

\[ M_u = \frac{1.92(16)^2}{8} = 61.4 \text{ ft·k} \]

Service moment:

\[ w_a = 0.32 \text{ k/ft} + 0.96 \text{ k/ft} = 1.28 \text{ k/ft} \]

\[ M_a = \frac{1.28(16)^2}{8} = 41.0 \text{ ft·k} \]

Try a pipe 8 x-strong, which has a plastic section modulus, \( Z_x = 31.0 \text{ in}^3 \).

The yield strength, \( F_y = 35 \text{ ksi} \)

Compactness ratio: \( \lambda = D/t = 18.5 \)

Determine the slender flange ratio limit from Table B4.1b: \( \lambda_p = \frac{0.07E}{F_y} = \frac{0.07(29,000)}{35} = 58.0 > \lambda \) (Compact)

By observation, \( \lambda < \frac{0.45E}{F_y} \), so Section F8 applies.

\[ \lambda_p = 2.42\sqrt{\frac{E}{F_y}} = 2.42\sqrt{\frac{29,000}{46}} = 60.8 > \lambda \]

\[ M_n = M_p = F_y \times Z_x = 35 \times 31.0 = 1,090 \text{ in·k} = 90.4 \text{ ft·k} \]

(F8-1)

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(90.4) = 81.4 \text{ ft·k} \)

ASD: \( M_n / \Omega_b = \frac{90.4}{1.67} = 54.1 \text{ ft·k} \)

V. AISC 360-05 Rect HSS E.9

References

Details

From reference (2):

Select a rectangular HSS compression member, with a length of 20 ft, to support a dead load of 85 kips and live load of 255 kips in axial compression. The base is fixed and the top is pinned.

Validation

Refer to reference.

**STAAD Space -- Page No.**
V. AISC 360-05 Tapered Tube Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered tube section member per both the LRFD and ASD methods of the AISC 360-05 code.

Details

A 5' × 5' portal frame consists of W12x72 columns and a steel tapered member for the beam.
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concreted torque of 0.75 in-kips at mid-span of the beam.

Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ F_y = 50 \text{ ksi} \]

Validation

Design Forces

By inspection, the right end of the beam (shallowest overall depth) governs under the symmetric loads present. The following design loads are used from the STAAD.Pro analysis are then used:

\[ M_z = 505.66 \text{ in·kips} \]
\[ F_y = 67.2 \text{ kips} \]
\[ F_x = 10.23 \text{ kips} \]

Section Properties

The section at the right end (OD = 10 in.) has the following properties:

Inner diameter, ID = 9 in.
Area, \[ A_y = \frac{\pi}{4}(OD^2 - ID^2) = 14.92 \text{ in}^2 \]
Form factor = \( 0.49 + 0.8 \left( \frac{t}{OD} \right) = 0.53 \)
Shear area, \[ A_y = 14.92(0.53) = 7.909 \text{ in}^2 \]
Moment of inertia,
\[ I = \frac{\pi}{64}(OD^4 - ID^4) = 168.8 \text{ in}^4 \]
Elastic section modulus, \[ S = \frac{\pi}{32} \frac{(OD^4 - ID^4)}{OD} = 33.76 \text{ in}^3 \]
Radius of gyration, \[ r = \sqrt{\frac{I}{A_y}} = \sqrt{\frac{168.8}{14.92}} = 3.363 \text{ in} \]
Plastic section modulus, \[ Z = \frac{OD^3 - ID^3}{6} = 45.17 \text{ in}^3 \]
HSS Torsional constant, $C = \frac{\pi}{2} (OD - t)^2 t = 70.88 \text{ in}^3$

**Section Classification**

Flange in compression

$$\lambda = \frac{OD}{t} = \frac{10}{0.5} = 20$$

Per Table B4.1-15a, $\lambda < \lambda_c = 0.11 \frac{E}{F_y} = 63.8$, therefore flanges are non-slender for compression. The web is similarly non-slender for compression.

Flange in bending (use half the longer flange width as the outstanding width):

$$\lambda = \frac{OD}{t} = \frac{10}{0.5} = 20$$

Per Table B4.1-15b, $\lambda < \lambda_c = 0.07 \frac{E}{F_y} = 40.6$, therefore flange is compact for bending.

**Compression Capacity**

$$\frac{hL}{r} = \frac{1.0(60)}{3.363} = 17.84 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4$$

$$F_e = \frac{n^2 E}{(\frac{hL}{r})^2} = \frac{n^2 \times 29,000}{(17.84)^2} = 899.4 \text{ ksi} \quad \text{(Eq. E3-4)}$$

$$\frac{F_y}{F_e} = \frac{50}{899.4} = 0.056 < 2.25$$

$$F_{crx} = 0.658 \left( \frac{F_y}{F_e} \right) = 0.658(0.056)50 = 48.85 \text{ ksi} \quad \text{(Eq. E3-2)}$$

$$P_n = \Delta g \times F_{crx} = 14.92 \times 48.85 = 729.0 \text{ kips} \quad \text{(Eq. E3-1)}$$

The axial capacity:

- The ultimate compression capacity (LRFD) = $\phi_n P_n = 0.9 \times 729.0 = 656.1 \text{ kips}$
- The allowable compression capacity (ASD) = $P_n/\Omega_c = 729.0 / 1.67 = 436.5 \text{ kips}$

**Shear Capacity**

The distance from the maximum shear force (ends) to zero shear force (mid-span), $L_v = L / 2 = 30 \text{ in}$.

The critical shear stress, $F_{cr}$, is the minimum of:

$$F_{cr1} = \frac{1.60E}{\sqrt{\frac{L_v}{OD} \frac{OD}{t} \frac{1}{4}}} = 633.4 \text{ ksi}$$

$$F_{cr2} = \frac{0.78E}{\frac{1}{3} \frac{OD}{t} ^{\frac{1}{2}}} = 252.9 \text{ ksi}$$

$$F_{cr3} = 0.6F_y = 30 \text{ ksi}$$

$F_{cr} = 30 \text{ ksi}$
Nominal shear capacity:

\[ V_n = F_{cr} A_g \sqrt{2} = 223.8 \text{ kips} \]

The shear capacity:

The ultimate shear capacity (LRFD) = \( \phi_c V_n = 0.9 \times 223.8 = 201.5 \text{ kips} \)

The allowable shear capacity (ASD) = \( V_n / \Omega_c = 223.8 / 1.67 = 134.0 \text{ kips} \)

Calculate Bending Capacity

Bending capacity in plastic yielding:

\[ M_p = F_y \times Z = 50 \times 45.17 = 2,259 \text{ in} \cdot \text{kips} \]

The bending capacity for flexural yielding:

The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 2,259 = 2,033 \text{ in} \cdot \text{kips} \)

The allowable bending capacity (ASD) = \( M_y / \Omega_b = 2,259 / 1.67 = 1,352 \text{ in} \cdot \text{kips} \)

Torsional Capacity

The critical stress, \( F_{cr} \), is the larger of:

\[ F_{cr1} = \frac{1.23E}{\sqrt{OD}} \left( \frac{OD}{t} \right)^{\frac{5}{4}} = 344.3 \text{ ksi} \]

\[ F_{cr2} = \frac{1.23E}{\left( \frac{OD}{t} \right)^{\frac{3}{2}}} = 194.5 \text{ ksi} \]

But shall not exceed:

\[ F_{cr3} = 0.6F_y = 30 \text{ ksi} \]

\( F_{cr} = 30 \text{ ksi} \)

Nominal torsional capacity:

\[ T_n = F_{cr} C = 2,126 \text{ in} \cdot \text{kips} \]

The torsional capacity:

The ultimate torsional capacity (LRFD) = \( \phi_c T_n = 0.9 \times 2,126 = 1,914 \text{ kips} \)

The allowable torsional capacity (ASD) = \( T_n / \Omega_c = 2,126 / 1.67 = 1,273 \text{ kips} \)

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:

\[ \frac{P_r}{P_c} = \frac{10.23}{656.1} = 0.016 < 0.2 \text{ (LRFD)} \]

\[ \frac{P_r}{P_c} = \frac{10.23}{436.5} = 0.023 < 0.2 \text{ (ASD)} \]

So use Eq. H1-1b for both methods: \( \frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{ex}} + \frac{M_{ry}}{M_{ey}} \right) \leq 1.0 \).
\[
\frac{0.016}{2} + \left( \frac{505.7}{2,033} + \frac{0}{2,033} \right) = 0.257 \text{ (LRFD)}
\]
\[
\frac{0.023}{2} + \left( \frac{505.7}{1,352} + \frac{0}{1,352} \right) = 0.386 \text{ (ASD)}
\]

V. AISC 360-05 Tapered I Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered I section member per both the LRFD and ASD methods of the AISC 360-05 code.

Details

A 5' × 5' portal frame consists of W12x72 columns and a steel tapered member for the beam.
The following load cases are evaluated:

1. A uniformly distributed load of -3.5 k/ft along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. Lateral loads at the top of the right column of -50 kips in the global X direction and 45 kips in the global Z direction (out of plane).
4. A concreted load of -100 kips in the global Y direction and a concentrated torque of 9 in-kips at mid-span of the beam.
Material Properties

E = 29,000 ksi
Fy = 50 ksi

Validation

Design Forces

By inspection, the left end of the beam (shallowest overall depth) governs under the symmetric loads present. The following design loads are used from the STAAD.Pro analysis are then used:

1. Mz = 32.26 in·kips, Fy = 8.755 kips
2. Mz = 677.6 in·kips, My = 2.942 in·kips, Mx = 5.106 in·kips, Fy = 22.49 kips, Fz = 0.098 kips, Fx = 24.70 kips
3. Mz = 275.9 in·kips, Mx = 4.497 in·kips, Fy = 50.23 kips, Fx = 5.473 kips
4. Mz = 654.5 in·kips, My = 5.298 in·kips, Mx = 9.192 in·kips, Fy = 22.50 kips, Fz = 0.177 kips, Fx = 24.35 kips

Section Properties

The section at the left end (D = 18 in.) has the following properties:

Web height, dw = 18 - 2×0.84 = 16.32 in.
Area, Ag = (0.84)(9 + 7.5) + 16.32 (0.36) = 19.74 in²
Shear area in local y, Ay = 16.32(0.36) = 5.875 in²
Shear area in local x, Ax = 0.84(9 + 7.5) = 13.86 in²
Dist to centroid y, c = \( \frac{7.5(0.84)\left(\frac{0.84}{2}\right) + 0.36(16.32)\left(\frac{0.84 + 16.32}{2}\right) + 9(0.84)\left(18 - \frac{0.84}{2}\right)}{19.74} \) = 9.548 in.
Moment of inertia about major axis,
\[ I_{zz} = \frac{7.5(0.84)^3}{12} + 7.5(0.84)\left(9.548 - \frac{0.84}{2}\right)^2 \]
\[ I_{zz} = \frac{0.36(16.32)^3}{12} + 0.36(16.32)\left(9.548 - \frac{16.32}{2} - \frac{0.84}{2}\right)^2 \]
\[ + \frac{9(0.84)^3}{12} + 9(0.84)\left(18 - \frac{0.84}{2} - 9.548\right)^2 \]
\[ I_{zz} = 1, 147 \text{ in}^4 \]
Moment of inertia about minor axis,
\[ I_{yy} = \frac{0.84(9)^3}{12} + \frac{16.32(0.36)^3}{12} + \frac{0.84(7.5)^3}{12} = 80.62 \text{ in}^4 \]
Elastic section modulus about major axis top flange fiber, S_{xx,top} = \( \frac{I_{zz}}{D - c} = \frac{1, 146}{18 - 9.548} = 135.5 \text{ in}^3 \)
Elastic section modulus about major axis bottom flange fiber, S_{xx,bottom} = \( \frac{I_{zz}}{c} = \frac{1, 146}{9.548} = 120.0 \text{ in}^3 \)
Elastic section modulus about minor axis, S_{yy} = \( \frac{I_{yy}}{b f_1 / 2} = \frac{80.62}{9 / 2} = 17.92 \text{ in}^3 \)
Radius of gyration about major axis, r_x = \( \sqrt{\frac{I_{zz}}{Ag}} = \sqrt{\frac{1, 147}{19.74}} = 7.619 \text{ in} \)
Radius of gyration about minor axis, r_y = \( \sqrt{\frac{I_{yy}}{Ag}} = \sqrt{\frac{80.62}{19.74}} = 2.021 \text{ in} \)
Location of the plastic neutral axis, \( y_{PNA} = 0.84 + \frac{19.74 - 2(7.5)(0.84)}{2 \times 0.36} = 10.75 \text{ in.} \)

Plastic section modulus about major axis,
\[
Z_{zt} = \frac{7.5(10.75)^2}{2} \left( \frac{7.5 \cdot 0.36}{2} \right) \left( 10.75 \cdot 0.84 \right)^2 + \frac{9(18 - 10.75)^2}{2} \left( \frac{9 \cdot 0.36}{2} \right) \left( 10.75 - 0.36 \right)^2 = 141.8 \text{ in}^3
\]

Plastic section modulus about minor axis, \( Z_y = \frac{0.84(9)^2}{4} + \frac{16.32(0.36)^2}{4} + \frac{0.84(7.5)^2}{4} = 29.35 \text{ in}^3 \)

Torsional constant, \( J = 9(0.84)^3 + 16.32(0.36)^3 + 7.5(0.84)^3 = 3.514 \text{ in}^4 \)

Section Classification

Flange in compression
\[
\lambda = \frac{b}{t} = \frac{1/2 \times 7.5}{0.84} = 4.464
\]
\[
k_c = \frac{4}{\sqrt{\frac{d_w}{t_w}}} = \frac{4}{\sqrt{\frac{16.32}{0.36}}} = 0.594
\]

Per Table B4.1a, \( \lambda < \lambda_r = 0.64\sqrt{\frac{E}{F_y}} = 0.64\sqrt{\frac{29,000}{50}} = 11.88 \), therefore flanges are non-slender for compression.

Web in compression
\[
\lambda = \frac{d_w}{t_w} = \frac{16.32}{0.36} = 45.33
\]

Per Table B4.1a, Case 5, \( \lambda > \lambda_r = 1.49\sqrt{\frac{E}{F_y}} = 1.49\sqrt{\frac{29,000}{50}} = 35.88 \), therefore the web is slender for compression.

Flange in bending (use half the longer flange width as the outstanding width):
\[
\lambda = \frac{b_f}{t_f} = \frac{9}{2(0.84)} = 5.36
\]

Per Table B4.1b, Case 11, \( \lambda < \lambda_p = 0.38\sqrt{\frac{E}{F_y}} = 0.38\sqrt{\frac{29,000}{50}} = 9.15 \), therefore flange is compact for bending.

Web in bending
\[
\lambda = \frac{d_w}{t_w} = \frac{16.32}{0.36} = 45.33
\]

Per Table B4.1b, Case 15, \( \lambda < \lambda_p = 3.76\sqrt{\frac{E}{F_y}} = 3.76\sqrt{\frac{29,000}{50}} = 90.55 \), therefore web is compact for bending.

Compression Capacity

About X Axis:
$\frac{k_x L_x}{r_x} = \frac{1.0(60)}{7.619} = 7.875 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4$  

$F_{ex} = \frac{n^2 E}{(k_x L_x/r_x)^2} = \frac{n^2 \times 29,000}{(7.875)^2} = 4.615$ ksi  

(Eq. E3-4)

$F_y/F_{ex} = \frac{50}{4.615} = 0.011 < 2.25$  

(Eq. E3-2)

$F_{cry} = 0.658 (F_y/F_{ex}) F_y = 0.658(0.011)50 = 49.77$ ksi

Since the web is slender, use the effective area. The effective width imperfection adjustment factors (Table E7.1):

c_1 = 0.18  
c_2 = 1.31

$F_{el} = \left(\frac{\lambda_y}{\lambda}ight)^2 F_y = \left(\frac{1.31}{45.88}\right)^2 = 53.76$ ksi  

(Eq. E7-5)

Therefore, the effective depth of the web in compression for the effective area:

$d_e = d_w \left(1 \cdot c_1 \sqrt{\frac{F_{el}}{F_{cry}}} \sqrt{\frac{F_{el}}{F_{cry}}} \right) = 16.32 \left(1 \cdot 0.18 \sqrt{\frac{53.76}{49.77}} \sqrt{\frac{53.76}{49.77}} \right) = 13.78$ in.  

(Eq. E7-3)

The reduced area of the section then becomes:

$A_e = 19.75 \cdot (16.32 \cdot 13.78) 0.36 = 18.84$ in.$^2$  

$P_{nx} = A_e \times F_{cry} = 18.84 \times 49.77 = 937.4$ kips  

(Eq. E7-1)

About Y Axis:

$k_y L_y/r_y = \frac{1.0(60)}{2.021} = 29.69 < 4.71 \sqrt{\frac{E}{F_y}} = 113.4$  

$F_{ey} = \frac{n^2 E}{(k_y L_y/r_y)^2} = \frac{n^2 \times 29,000}{(29.69)^2} = 324.7$ ksi  

(Eq. E3-4)

$F_y/F_{ey} = \frac{50}{324.7} = 0.154 < 2.25$  

(Eq. E3-2)

$F_{cry} = 0.658 (F_y/F_{ey}) F_y = 0.658(0.154)50 = 46.88$ ksi

Therefore, the effective depth of the web in compression for the effective area:

$d_e = d_w \left(1 \cdot c_1 \sqrt{\frac{F_{el}}{F_{cry}}} \sqrt{\frac{F_{el}}{F_{cry}}} \right) = 16.32 \left(1 \cdot 0.18 \sqrt{\frac{53.76}{46.88}} \sqrt{\frac{53.76}{46.88}} \right) = 14.11$ in.  

(Eq. E7-3)

The reduced area of the section then becomes:

$A_e = 19.75 \cdot (16.32 \cdot 14.11) 0.36 = 18.93$ in.$^2$
\[ P_{ny} = A_e \times F_{cy} = 18.93 \times 46.88 = 887.4 \text{ kips} \]  
(Eq. E7-1)

The Y axis governs; \( P_n = P_{ny} \). The axial capacity:

- The ultimate compression capacity (LRFD) = \( \phi P_n = 0.9 \times 887.4 = 798.3 \text{ kips} \)
- The allowable compression capacity (ASD) = \( P_n / \Omega_c = 887.4 / 1.67 = 531.4 \text{ kips} \)

**Calculate Bending Capacity**

Bending capacity in plastic yielding about Y axis:

\[ M_y = F_y \times Z_y = 50 \times 29.35 = 1,468 \text{ in} \cdot \text{kips} > 1.6F_y \times S_y = 1.6 (50)(17.92) = 1,434 \text{ in} \cdot \text{kips} \]

Use \( M_y = 1,434 \text{ in} \cdot \text{kips} \)

The bending capacity for flexural yielding about the Y axis:

- The ultimate bending capacity (LRFD) = \( \phi b M_y = 0.9 \times 1,434 = 1,290 \text{ in} \cdot \text{kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,434 / 1.67 = 858.4 \text{ in} \cdot \text{kips} \)

Bending capacity in plastic yielding about X axis:

The section is capacity is determined as per F4 in the specification. The design moments for this are from Load Case 4 and occur at mid-span (\( d = 18.9 \text{ in.} \)). The section properties at this location are:

- \( I_{zz} = 1,278 \text{ in}^4 \)
- \( I_{yy} = 80.63 \text{ in}^4 \)
- \( c = 10.01 \text{ in} \)
- \( h_c = 2 \times (10.01 - 0.84) = 18.35 \text{ in.} \)
- \( S_x = 143.8 \text{ in}^3 \)
- \( Z_x = 150.7 \text{ in}^3 \)

\[ M_{yc} = F_y \times S_{yc} = 50 \times 143.8 = 7,192 \text{ ksi} \]
\[ M_p = F_y \times Z_x = 50 \times 150.7 = 7,535 \text{ ksi} \leq 1.6 F_y \times S_x = 11,504 \text{ ksi} \]

The moment of inertia of the compression flange about the Y axis \( I_{yc} = \frac{0.84 (7.5)^3}{12} = 29.53 \text{ in}^4 \), and thus

\[ I_{yc} / I_y = \frac{29.53}{80.63} = 0.366 > 0.23 \Rightarrow \frac{h_c}{t_w} = \frac{18.35}{0.36} = 50.99 < \lambda_{pw} = 90.55 \text{ (limiting slenderness for a compact web per Table B4.1b case 15), so the web plastification factor, } R_{pc} \text{ is determined as:} \]

\[ R_{pc} = \frac{M_p}{M_{yc}} = \frac{7,535}{7,192} = 1.048 \]  
(F4-9a)

Bending capacity in plastic yielding about Y axis:

\[ M_n = R_{pc} \times M_{yc} = 1.048 \times 7,192 = 7,535 \text{ in} \cdot \text{kips} \]

The bending capacity for flexural yielding about the Y axis:

- The ultimate bending capacity (LRFD) = \( \phi b M_y = 0.9 \times 7,535 = 6,782 \text{ in} \cdot \text{kips} \)
- The allowable bending capacity (ASD) = \( M_y / \Omega_b = 7,535 / 1.67 = 4,512 \text{ in} \cdot \text{kips} \)

**Interaction Ratio for Bending and Compression**

Check the interaction ratio for Load Case 3:
\[
\frac{P_r}{P_c} = \frac{5.473}{798.3} = 0.007 < 0.2 \text{ (LRFD)}
\]

\[
\frac{P_r}{P_c} = \frac{5.479}{531.4} = 0.010 < 0.2 \text{ (ASD)}
\]

So use Eq. H1-1b for both methods:

\[
\frac{P_r}{P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0.
\]

\[
\frac{0.007}{2} + \left( \frac{1.225}{6,783} + \frac{0}{1,290} \right) = 0.184 \text{ (LRFD)}
\]

\[
\frac{0.010}{2} + \left( \frac{1.225}{4,513} + \frac{0}{858} \right) = 0.277 \text{ (ASD)}
\]

### V. AISC 360-05 UPT Square Hollow Section

Verify the axial compression capacity, shear capacity, flexure capacity, torsional capacity, and interaction ratio of a user-provided hollow square section member per both the LRFD and ASD methods of the AISC 360-05 code.

#### Details

A 5' × 5' portal frame consists of W12x72 columns and a UPT SHS member for the beam. The section outer depth, $D$, is 8" and the thickness, $t$, is 0.30".
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concentrated torque of 0.75 in-kips at mid-span of the beam.

Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ F_y = 50 \text{ ksi} \]

Validation

Design Forces
The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 599.6 \text{ in-kips}, \ F_y = 67.5 \text{ kips} \)

**Section Properties**

- Inner depth, \( d = 8 - 2 \times 0.30 = 7.40 \text{ in.} \)
- Area, \( A_g = D^2 - d^2 = 9.24 \text{ in}^2 \)
- Shear area, \( A_w = 2 \times D \times t_w = 4.80 \text{ in}^2 \)
- Moment of inertia, \( I = \frac{1}{12} (D^4 - d^4) = 91.45 \text{ in}^4 \)
- Elastic section modulus, \( S = \frac{I}{D/2} = \frac{91.45}{8/2} = 22.86 \text{ in}^3 \)
- Radius of gyration, \( r = \sqrt{\frac{I}{A_g}} = \sqrt{\frac{91.45}{9.24}} = 3.146 \text{ in} \)
- Plastic section modulus, \( Z = \frac{1}{6} (D^3 - d^3) = 26.69 \text{ in}^3 \)
- HSS Torsional constant, \( C = 2 \left( B \cdot t_w \right) \left( D - t_w \right) t_w \cdot 4.5 (4 \cdot \pi) t_w^3 = 35.47 \text{ in}^3 \)

**Section Classification**

- The design thickness, \( t = 0.93 \times t_w = 0.279 \text{ in} \)
- The design depth, \( d = D - 3t = 7.163 \text{ in} \)
- Flange in compression
  \(
  \lambda = \frac{d}{t} = \frac{7.163}{0.279} = 25.67
  \)
- Per Table 4.1a Case 6, \( \lambda < \lambda_r = 1.40 \sqrt{\frac{E}{F_y}} = 1.40 \sqrt{\frac{29,000}{50}} = 33.72 \), therefore flanges are non-slender for compression. Similar for the web of the square section.

  **Flexure classification of flange:**

  - Per Table B4.1-12, \( \lambda < \lambda_p = 1.12 \sqrt{\frac{E}{F_y}} = 1.12 \sqrt{\frac{29,000}{50}} = 26.97 \), therefore flange is compact for bending.

  **Flexure classification of web:**

  - Per Table B4.1-13, \( \lambda < \lambda_p = 2.42 \sqrt{\frac{E}{F_y}} = 2.42 \sqrt{\frac{29,000}{50}} = 58.28 \), therefore web is compact for bending.

**Compression Capacity**

- Effective slenderness ratio:
  \( \frac{k_x L_x}{r_x} = \frac{1.0(60)}{3.146} = 19.07 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \)

- Elastic buckling stress:
  \( F_e = \frac{n^2 E}{\left( \frac{k_x L_x}{r_x} \right)^2} = \frac{n^2 \times 29,000}{(19.07)^2} = 787 \text{ ksi} \) \hspace{1cm} (Eq. E3-4)
\[
\frac{F_y}{F_e} = \frac{50}{787} = 0.064 < 2.25
\]

Critical buckling stress:

\[
F_{cr} = 0.658 \left(\frac{F_y}{F_e}\right)^{0.658(0.064)}50 = 48.68 \text{ ksi}
\]  
(Eq. E3-2)

Nominal buckling strength:

\[
P_n = A_g \times F_{cr} = 9.24 \times 48.68 = 449.9 \text{ kips}
\]  
(Eq. E3-1)

The axial capacity:

The ultimate compression capacity (LRFD) = \(\phi P_n = 0.9 \times 449.9 = 404.9 \text{ kips}\)

The allowable compression capacity (ASD) = \(P_n/\Omega_c = 449.9 / 1.67 = 269.4 \text{ kips}\)

Calculate Shear Capacity

The nominal shear strength:

\[
V_n = 0.6 \times F_y \times A_w \times C_{v2}
\]  
(Eq. G4-1)

where

\[
C_{v2} = 1.0 \text{ per Section G2.2 with } h/t = 25.67 \text{ and } K_v = 5.
\]

\[
V_n = 0.6 (50) (4.80) (1.0) = 144 \text{ kips}
\]

The shear capacity:

The ultimate shear capacity (LRFD) = \(\phi_v V_n = 0.9 \times 144 = 129.6 \text{ kips}\)

The allowable shear capacity (ASD) = \(V_n/\Omega_v = 144 / 1.67 = 86.23 \text{ kips}\)

Calculate Bending Capacity

Bending capacity in plastic yielding (compact section):

\[
M_p = F_y \times Z_x = 50 \times 26.69 = 1,335 \text{ in·kips}
\]  
(Eq. F7-1)

The bending capacity for flexural yielding about the Y axis:

The ultimate bending capacity (LRFD) = \(\phi_b M_y = 0.9 \times 1,335 = 1,201 \text{ in·kips}\)

The allowable bending capacity (ASD) = \(M_y/\Omega_b = 1,335 / 1.67 = 799.2 \text{ in·kips}\)

Torsional Capacity

\[
\frac{h}{t} = 25.67 < 2.45 \sqrt{\frac{F_e}{F_y}} = 59.0
\]

\[
F_{cr} = 0.6F_y = 30 \text{ ksi}
\]

Nominal torsional capacity:

\[
T_n = F_{cr} \times C = 1,064 \text{ ksi}
\]

The torsional capacity:

The ultimate torsional capacity (LRFD) = \(\phi_T T_n = 0.9 \times 1,064 = 957.7 \text{ kips}\)

The allowable torsional capacity (ASD) = \(T_n/\Omega_T = 1,064 / 1.67 = 637.2 \text{ kips}\)

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:
Verification Examples
V.09 Steel Design

\[
\frac{P_r}{P_c} = \frac{11.80}{404.9} = 0.029 < 0.2 \text{ (LRFD)}
\]

\[
\frac{P_r}{P_c} = \frac{11.80}{269.4} = 0.044 < 0.2 \text{ (ASD)}
\]

So use Eq. H1-1b for both methods:

\[
\frac{P_r}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0.
\]

\[
\frac{0.029}{2} + \left( \frac{599.7}{1,201} + \frac{0}{1,201} \right) = 0.514 \text{ (LRFD)}
\]

\[
\frac{0.044}{2} + \left( \frac{599.7}{799.2} + \frac{0}{799.2} \right) = 0.765 \text{ (ASD)}
\]

STAAD.Pro Input

The file C:\Users\Public\Public Documents\STAAD.Pro CONNECT Edition\Samples\Verification Models\09 Steel Design\US\AISC\AISC 360-05 UPT Square Hollow Section.STD is typically installed with the program.

The following D1.A.6 Design Parameters (on page 1093) are used:

- The welded SHS member is specified using STP 2
- Shear lag factor, $U$ for tension rupture capacity is specified by SLF 0.8

The remaining parameters all use their default values.

V. AISC 360-05 UPT Pipe Section

Verify the axial compression capacity, flexure capacity, and interaction ratio of a tapered I section member per both the LRFD and ASD methods of the AISC 360-05 code.

Details

A 5' × 5' portal frame consists of W12x72 columns and a UPT pipe member for the beam. The pipe outer diameter, \( D \), is 10" and the thickness, \( t \), is 0.25".
The following load cases are evaluated:

1. A uniformly distributed load of -2.25 k/in along the beam in the global Y direction.
2. Lateral loads at the top of the left column of 50 kips in the global X direction and 25 kips in the global Z direction (out of plane).
3. A concentrated torque of 0.75 in·kips at mid-span of the beam.

Material Properties

\[ E = 29,000 \text{ ksi} \]
\[ F_y = 50 \text{ ksi} \]

Validation

Design Forces
The following design loads are used from the STAAD.Pro analysis are then used:

1. \( M_z = 599.6 \text{ in-kips} \), \( F_y = 67.5 \text{ kips} \)

**Section Properties**

Inner diameter, \( d = 10 - 2 \times 0.25 = 9.5 \text{ in.} \)

Area, \( A_g = \frac{\pi}{4} (D^2 - d^2) = 7.66 \text{ in}^2 \)

Shear area, \( A_y = A_x = A_g / 2 = 3.83 \text{ in}^2 \)

Moment of inertia, \( I_x = I_y = \frac{\pi}{64} (D^4 - d^4) = 91.05 \text{ in}^4 \)

Elastic section modulus, \( S_{xx} = \frac{I_x}{D/2} = \frac{91.05}{10/2} = 18.21 \text{ in}^3 \)

Radius of gyration, \( r_x = \sqrt{\frac{I_x}{A_g}} = \sqrt{\frac{91.05}{7.66}} = 3.448 \text{ in} \)

Plastic section modulus, \( Z_x = \frac{1}{6} (D^3 - d^3) = 23.77 \text{ in}^3 \)

HSS Torsional constant, \( C = \frac{n}{2} (D - t)^2 t = 37.33 \text{ in}^3 \)

**Section Classification**

Flange in compression

\[ \lambda = \frac{D}{t} = \frac{10}{0.25} = 40 \]

Per Table 4.1a Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} = 0.11 \frac{29,000}{50} = 63.8 \), therefore flanges are non-slender for compression.

Web in compression

Per Table 4.1a, Case 9, \( \lambda < \lambda_r = 0.11 \frac{E}{F_y} = 0.11 \frac{29,000}{50} = 63.8 \), therefore the web is non-slender for compression.

Flexure classification:

Per Table 4.1b, Case 20, \( \lambda < \lambda_p = 0.07 \frac{E}{F_y} = 0.07 \frac{29,000}{50} = 40.6 \), therefore flange is compact for bending.

**Compression Capacity**

Effective slenderness ratio:

\[ \frac{k_x L_x}{r_x} = \frac{1.0(60)}{3.448} = 17.40 < 4.71 \sqrt{\frac{E}{F_y}} = 4.71 \sqrt{\frac{29,000}{50}} = 113.4 \]

Elastic buckling stress:

\[ F_e = \frac{\frac{E}{(k_x L_x)^2}}{r_x} = \frac{E}{(17.40)^2} = 945 \text{ ksi} \]  

(Eq. E3-4)

\[ \frac{F_y}{F_e} = \frac{50}{945} = 0.053 < 2.25 \]
Critical buckling stress:

\[ F_{cr} = 0.658 F_y = 65.8 \times 50 = 48.91 \text{ ksi} \]  \hspace{1cm} (Eq. E3-2)

Nominal buckling strength:

\[ P_n = A_g \times F_{cr} = 7.66 \times 48.91 = 374.5 \text{ kips} \]  \hspace{1cm} (Eq. E3-1)

The axial capacity:

The ultimate compression capacity (LRFD) = \( \phi_c P_n = 0.9 \times 374.5 = 337.0 \text{ kips} \)

The allowable compression capacity (ASD) = \( P_n / \Omega_c = 374.5 / 1.67 = 224.3 \text{ kips} \)

Calculate Shear Capacity

Critical stress is the minimum of \( F_{cr1}, F_{cr2}, \) and \( F_{cr3} \):

\[ F_{cr1} = \frac{1.23E}{\sqrt{D/D_t^{3/4}}} = 144.8 \text{ ksi} \]

\[ F_{cr2} = \frac{0.78E}{(D/D_t)^{3/2}} = 89.4 \text{ ksi} \]

\[ F_{cr3} = 0.6F_y = 30 \text{ ksi} \]

So, \( F_{cr} = 30 \text{ ksi} \).

The nominal shear strength:

\[ V_n = F_{cr} \times A_x = 30 \times 3.83 = 114.9 \text{ kips} \]

The axial capacity:

The ultimate shear capacity (LRFD) = \( \phi_v V_n = 0.9 \times 114.9 = 103.4 \text{ kips} \)

The allowable shear capacity (ASD) = \( V_n / \Omega_v = 114.9 / 1.67 = 68.78 \text{ kips} \)

Calculate Bending Capacity

Bending capacity in plastic yielding (compact section):

\[ M_y = F_y \times Z_x = 50 \times 23.77 = 1,189 \text{ in} \cdot \text{kips} \]  \hspace{1cm} (Eq F8-1)

The bending capacity for flexural yielding about the Y axis:

The ultimate bending capacity (LRFD) = \( \phi_b M_y = 0.9 \times 1,189 = 1,070 \text{ in} \cdot \text{kips} \)

The allowable bending capacity (ASD) = \( M_y / \Omega_b = 1,189 / 1.67 = 711.7 \text{ in} \cdot \text{kips} \)

Interaction Ratio for Bending and Compression

Check the interaction ratio for Load Case 1:

\[ \frac{P_r}{P_c} = \frac{11.75}{337.0} = 0.034 < 0.2 \text{ (LRFD)} \]

\[ \frac{P_r}{P_c} = \frac{11.75}{224.3} = 0.052 < 0.2 \text{ (ASD)} \]
So use Eq. H1-1b for both methods: \( \frac{P}{2P_c} + \left( \frac{M_{rx}}{M_{cx}} + \frac{M_{ry}}{M_{cy}} \right) \leq 1.0 \).

\[
\frac{0.034}{2} + \left( \frac{599.6}{1,070} + \frac{0}{1,070} \right) = 0.578 \text{ (LRFD)}
\]

\[
\frac{0.052}{2} + \left( \frac{599.6}{711.7} + \frac{0}{711.7} \right) = 0.869 \text{ (ASD)}
\]

**Calculate Torsion Capacity**

Critical stress is the minimum of \( F_{cr,1}, F_{cr,2}, \text{ and } F_{cr,3} \). From shear calculations, \( F_{cr} = 30 \text{ ksi} \).

The nominal shear strength:

\[ T_n = F_{cr} \times C = 30 \times 37.33 = 1,120 \text{ in\cdotkips} \]

The axial capacity:

The ultimate torsional capacity (LRFD) = \( \phi T_n = 0.9 \times 1,120 = 1,008 \text{ in\cdotkips} \)

The allowable torsional capacity (ASD) = \( T_n / \Omega_T = 114.9 / 1.67 = 670.6 \text{ in\cdotkips} \)

The following [D1.A.6 Design Parameters](on page 1093) are used:

- The welded pipe member is specified using STP 2
- Shear lag factor, $U$ for tension rupture capacity is specified by SLF 0.8

The remaining parameters all use their default values.

*All units are - KIP FEET (UNLESS OTHERWISE Noted)*
V. AISC 360-05 W D.1

References

Details
From reference (2):

Select an 8 in. W-shape, ASTM A992, to carry a dead load of 30 kips and a live load of 90 kips in tension. The member is 25 ft long. Verify the member strength by both LRFD and ASD with the bolted end connection shown. Verify that the member satisfies the recommended slenderness limit.

Validation
Refer to reference.

V. AISC 360-05 W E.1C

References

Details

From reference (2):

Calculate the available strength of a W14×132 column with unbraced lengths of 30 ft in both axes. The material properties and loads are as given in Example E.1a.

From Example E.1a (also from Reference (1), p.E-4):

...an ASTM A992 (Fy = 50 ksi) W-shape column to carry an axial dead load of 140 kips and live load of 420 kips.

Validation

Refer to reference.

V. AISC 360-05 W E.1D

References

Details
From reference (2):

Calculate the available strength of a W14×90 with a strong axis unbraced length of 30 ft and weak axis and torsional unbraced lengths of 15 ft. The material properties and loads are as given in Example E.1b. [which then references Example E.1a]

From Example E.1a (also from Reference (1), p.E-4):

...an ASTM A992 (Fy = 50 ksi) W-shape column to carry an axial dead load of 140 kips and live load of 420 kips.

Validation
Refer to reference.

V. AISC 360-05 W Flex Memb F.1-1

References

Details
From reference (2):

Select an ASTM A992 W-shape beam with a simple span of 35 feet. Limit the member to a maximum nominal depth of 18 in. Limit the live load deflection to L/360. The nominal loads are a uniform dead load of 0.45 kip/ft and a uniform live load of 0.75 kip/ft. Assume the beam is continuously braced.

Validation
Refer to reference.

STAAD.PRO CODE CHECKING - ( AISC-360-05-ASD) v3.3a

ALL UNITS ARE - KIP FEET (UNLESS OTHERWISE Noted)
V. AISC 360-05 W Local Buckling F.3

References

Details
From reference (2):
Select an ASTM A992 W-shape beam with a simple span of 40 feet. The nominal loads are a uniform dead load of 0.05 kip/ft and two equal 18 kip concentrated live loads acting at the third points of the beam. The beam is continuously braced. Also calculate the deflection.

Validation
Refer to reference.

Verification Examples
V.09 Steel Design

V. AISC 360-05 W LTB Test F.1-2

References

Details
From reference (2):

Verify the strength of the W18×50 beam selected in V. AISC 360-05 W Flex Memb F.1-1 (on page 5602) if the beam is braced at the ends and third points rather than continuously braced.

Validation
Refer to reference.

V. AISC 360-05 W Memb Selection F.4

**References**

Details

From reference (2):

Select an ASTM A992 W-shape flexural member by the moment of inertia, to limit the live load deflection to 1 in. The span length is 30 ft. The nominal loads are a uniform dead load of 0.80 kip/ft and a uniform live load of 2 kip/ft. Assume the beam is continuously braced.

Validation

Refer to reference.

V.09 Steel Design

V. AISC 360-05 W Shape Strong Axis Shear G-1

References

Details
From reference (2):

Verify the shear strength of a W24×62 ASTM A992 beam with end shears of 48 kips from dead load and 145 kips from live load.

Validation
Refer to reference.

STAAD.Pro

5634 User Manual
V. AISC 360-05 W Tens and Bending H3

References

Details
From reference (2):
Select an ASTM A992 W-shape with a 14-in. nominal depth to carry nominal forces of 29 kips from dead load and 87 kips from live load in axial tension, as well as the following nominal moments:

\[
\begin{align*}
M_{xD} &= 32.0 \text{ kip-ft} \\
M_{xL} &= 96.0 \text{ kip-ft} \\
M_{yD} &= 11.3 \text{ kip-ft} \\
M_{yL} &= 33.8 \text{ kip-ft}
\end{align*}
\]

The unbraced length is 30 ft and the ends are pinned. Assume the connections are made with no holes.

**Validation**

Refer to reference.

References

Details
From reference (2):

A WT6×20, ASTM A992, member has a length of 30 ft and carries a dead load of 40 kips and a live load of 120 kips in tension. Assume the end connection is fillet welded and has a length of 16 in. Verify the member strength by both LRFD and ASD. Assume that the gusset plate and the weld have been checked and are satisfactory.

Validation
Refer to reference.

**References**

**Details**

From reference (2):

---

STAAD.Pro 5653 User Manual
Select an ASTM A992 WT beam with a simple span of 6 ft. The toe of the stem of the WT is in tension. The nominal loads are a uniform dead load of 0.08 kip/ft and a uniform live load of 0.24 kip/ft. There is no deflection limit for this member. Assume full lateral support.

**Validation**

Ultimate moment:

\[ w_u = 1.2(0.08 \text{ kip/ft}) + 1.6(0.24 \text{ kip/ft}) = 0.48 \text{ kip/ft} \]

\[ M_u = \frac{0.48(6)^2}{8} = 2.16 \text{ ft-k} \]

Service moment:

\[ w_a = 0.08 \text{ kip/ft} + 0.24 \text{ kip/ft} = 0.32 \text{ kip/ft} \]

\[ M_a = \frac{0.32(6)^2}{8} = 1.44 \text{ ft-k} \]

Try a WT5×6, which has a plastic section modulus, \( Z_x = 2.20 \text{ in}^3 \) and a section modulus, \( S_x = 1.22 \text{ in}^3 \).

**Flexural Yielding**

\[ M_n = M_p = F_y \times Z_x = 50 \times 2.20 = 110 \text{ in-k} \]

\[ = 1.6 	imes 50 \times 1.22 = 97.6 \text{ in-k} \] (F9-2)

Lateral-torsional buckling does not govern since the member is continuously braced.

Flange compactness: \( \lambda = \frac{b_f}{2t_f} = 9.43 \)

Determine the compact and slender flange ratio limits from Table B4.1b:

\[ \lambda_{pf} = 0.38 \sqrt{\frac{E}{F_y}} = 0.38 \sqrt{\frac{29,000}{46}} = 9.15 \]

\[ \lambda_{rf} = 1.0 \sqrt{\frac{E}{F_y}} = 1.0 \sqrt{\frac{29,000}{46}} = 24.1 \]

Thus, the section has a non-compact flange.

\[ M_n = \left[ M_p - (M_p - 0.7F_yS_{xc}) \left( \frac{\lambda - \lambda_{pf}}{\lambda_{rf} - \lambda_{pf}} \right) \right] = \left[ 110 - (110 - 0.7 \times 50 \times 3.20) \left( \frac{9.43 - 9.15}{24.1 - 9.15} \right) \right] = 110 \text{ in-k} > \]

So use \( M_n = 97.6 \text{ in-k} = 8.13 \text{ ft-k} \)

The available flexural strength:

LRFD: \( \phi_b M_n = 0.90(8.13) = 7.32 \text{ ft-k} \)

ASD: \( M_n / \Omega_b = 8.13 / 1.67 = 4.87 \text{ ft-k} \)

### CHECK FOR BENDING-LATERAL TORSIONAL BUCKLING
V. AISC ASD - Column Compression Capacity 1

Determine the axial compression capacity of a W14X132 column.

Reference

Related Links
• D1.B.1.1 Allowables per AISC Code (on page 1123)

Problem

\[ F_y = 36 \text{ ksi} \]
\[ K_y L_y = 16 \text{ ft} \]
\[ K_z L_z = 31 \text{ ft} \]

Comparison

The reported STAAD.Pro value is obtained by multiplying \( FA \) times \( AX \) from the STAAD.Pro output:

\[ 17.36 \text{ ksi (38.8 in}^2) = 673.6 \text{ kips} \]

V. AISC ASD - MC Beam Load Capacity

Determine the bending (transverse load carrying) capacity of an MC18x58 channel. The beam is laterally supported along its entire length.

Reference

Related Links

• D1.B.1.1 Allowables per AISC Code (on page 1123)

Problem

\[ F_y = 36 \, \text{ksi} \]

\[ L = 25 \, \text{ft} \]

Comparison

The reported STAAD.Pro value is obtained by dividing the applied load (using the table capacity) by the reported STAAD.Pro critical ratio \[ = \frac{43}{0.995} = 43.2 \].

V. AISC ASD - 2D Frame Validation

Determine the allowable stresses (per 1989 AISC code) for the members of the structure as shown in the figure. Also, perform a code check for these members based on the results of the analysis.
Reference

Related Links
- D1.B.1.1 Allowables per AISC Code (on page 1123)

Problem

Members 1, 2 = W12X26, Members 3, 4 = W14X43
Members 5, 6, 7 = W16X36, Memb 8= L40404, Memb 9 = L50506
F = 15 kip (wind load)
w = 2 kip/ft (dead load + live load)
Steel: Fy = 36ksi

Hand Calculation

Member 1

Size W12x26, L = 10 ft., a = 7.65 in², S_z = 33.39 in³
Per Section F2 is the lower value for the yielding and lateral-torsional buckling limit states:
M_n = M_p = F_y Z_x = 36ksi × 37.2 in³ = 1,339 in·k = 111.3 ft·k

\[
L_p = 1.76 r_y \sqrt{\frac{E}{F_y}} = 1.76 \left(1.51\text{in}\right) \sqrt{\frac{29,000\text{ksi}}{36\text{ksi}}} = 75.4\text{in}
\]
From clause F1-2, page 5-45 of Manual, $L_c = 6.85\text{ ft.}$

From observation Load case 1 will govern,

$F_x = 25.0\text{ kip (compression)}, M_z = 56.5\text{ ft-kip}$

Area of compressive flange = $6.49*0.38 = 2.466\text{ in}^2$

Allowable bending stress, per Clause F1-8 (page 5-47 of Manual)

$$f_b = 12. \cdot 1000 \cdot 1.0/[10 \cdot 12 \cdot (12.22/2.466)] = 20.1817\text{ ksi}$$

$$(k_l/r)y = 120/1.5038 = 79.8, \text{ so } f_a = 15.38\text{ ksi}$$

Stresses per Table C-36 (page 3-16 of manual)

$$f_a = 25./7.65 = 3.268$$

$$f_b = 56.5 \cdot 12/33.39 = 20.31\text{ ksi}$$

$$(k_l/r)z = 120/5.1639 = 23.238, \text{ so } F'_{ez} = 276.54\text{ ksi}$$

Equation H1-1, page 5-54 of Manual

$$3.268/15.38 + 0.85 \cdot 20.31 / [(1-3.268/276.54) \cdot 20.1817] = 1.078$$

Equation H1-2, page 5-54 of Manual.

$$3.268/(0.6 \cdot 36) + 20.31/20.1817 = 1.1576$$

Therefore, equation H1-2 governs and ratio = 1.1576

**Member 2**

Size W12x26, $L = 5\text{ ft}, a = 7.65\text{ in}^2, S_z = 33.39\text{ in}^3$

From observation load case 1 will govern,

$F_x = 8.71\text{ kip (compression)}, M_z = 56.50\text{ ft-kip}$

Since $L$ is less than $L_c = 6.85\text{ft}$, per Clauses F1-1 & F1-2 (page 5-45 of Manual)

$$f_b = 0.66 \cdot 36 = 23.76\text{ ksi}$$

$$(k_l/r)y = 60/1.5038 = 39.90, \text{ so } f_a = 19.19\text{ ksi}$$

Per Table C-36 (page 3-16 of Manual)

$$f_a = 8.71/7.65 = 1.1385, f_b = 56.5 \cdot 12/33.39 = 20.31\text{ ksi}$$

Since $f_a/F_a$ less than 0.15, apply equation H1-3 (page 5-54 of Manual)

$$1.1385/19.19 + 20.31/23.76 = .0593 + .8548 = 0.9141$$

**Member 3**

Size W14X43, $L = 11\text{ ft}, a = 12.6\text{ in}^2, S_z = 62.7\text{ in}^3$

From observation load case 3 will govern,

$F_x = 25.5\text{ kip (compression)}, M_z = 112.173\text{ ft-kip}$

Referring to clause F1-2, page 5-45 of Manual.

$L_c = 8.4\text{ ft.}$ Therefore
\[ f_b = 0.6 \cdot 36 = 21.6 \text{ ksi} \]

\[ (kl/r)y = 132/1.8941 = 69.69, \]

so \( f_a = 16.46 \text{ ksi} \) per Table C-36 (page 3-16 of Manual)

\[ f_a = 25.5/12.6 = 2.024 \]

\[ f_b = 112.173 \cdot 12/62.66 = 21.48 \text{ ksi} \]

since \( f_a/F_a \) less than 0.15, use equation H1-3, page 5-54 of Manual

\[ 2.024/16.46 + 21.48/21.6 = 0.123 + 0.994 = 1.117 \]

**Member 4**

Size W14x43, \( L = 4 \text{ ft}, a = 12.6 \text{ in}^2, Sz = 62.7 \text{ in}^3 \)
From observation, load case 3 will govern,
\( F_x = 8.75 \text{ kip (tension)}, M_z = 112.173 \text{ ftkip} \)
Since \( L \) is less than \( L_c = 8.4 \text{ ft} \)
\[ f_b = 0.66 \cdot 36 = 23.76 \text{ ksi} \]
Clause F1-1 (page 5-45 of Manual)
\[ f_a = 8.75/12.6 = 0.694 \]
\[ f_b = 112.73 \cdot 12/62.66 = 21.48 \text{ ksi} \]
Combined tension and bending, use equation H2-1, page 5-55 of Manual.
\[ 0.694/(0.6 \cdot 36) + 21.48/23.76 = 0.032 + 0.904 = 0.936 \]

**Member 5**

Size W16x36, \( L = 5 \text{ ft}, a = 10.6 \text{ in}^2, Sz = 56.49 \text{ in}^3 \)
From observation, load case 3 will govern.
\( F_x = 14.02 \text{ kip (compression)}, M_z = 57.04 \text{ ftkip} \)
Since \( L \) is less than \( L_c = 7.37 \) (per Clause F1-2, page 5-45 of Manual)
\[ f_b = 0.66 \cdot 36 = 23.76 \text{ ksi} \]
\[ (kl/r)y = 60./1.52 = 39.47 \]
so \( f_a = 19.23 \text{ ksi} \) per Table C-36 (page 3-16 of Manual)
\[ f_a = 14.02/10.6 = 1.32 \]
\[ f_b = 57.04 \cdot 12/56.5 = 12.12 \text{ ksi} \]
Since \( f_a/F_a \) less than 0.15, use equation H1-3, page 5-54 of Manual
\[ 1.32/19.23 + 12.12/23.76 = 0.069 + 0.510 = 0.579 \]

**Member 6**

Size W16x36, \( L = 16 \text{ ft}, a = 10.6 \text{ in}^2, Sz = 56.49 \text{ in}^3 \)
From observation, load case 1 will govern. Forces at midspan are
\[ F_x = 5.65 \text{ kip (compression)}, M_z = 71.25 \text{ ft-kip} \]

From Chapter F of the AISC ASD 9th ed. specs., with \( C_b = 1.0 \),

\[
(102,000 C_b/F_y)^{1/2} = 53.229
\]

\[
(510,000 C_b/F_y)^{1/2} = 119.02
\]

\[ L/rT = 192/1.79 = 107.26 \]

\[ 53.229 < 107.26 < 119.02 \]

Therefore \( F_b \) (as per F1-6, page 5-47 of Manual)

\[
[(2/3) - 36 \cdot 107.26 \cdot 107.26/(1,530,000)] \cdot 36 = 14.25 \text{ ksi}
\]

\[ (KL/r)y = 192/1.5203 = 126.29 \]

so \( f_a = 9.36 \) per Table C-36 (page 3-16 of Manual)

\[ f_a = 5.65/10.6 = 0.533 \]

\[ f_b = 71.25 \times 12/56.49 = 15.14 \text{ ksi} \]

Since \( f_a/F_a \) less than 0.15 use formula [H1-3, page 5-54 of Manual]

\[ 0.533/9.36 + 15.14/14.25 = 0.057 + 1.062 = 1.119 \]

**Member 7**

Size W16x36, \( L = 4 \text{ ft}, a = 10.6 \text{ in}^2, Sz = 56.49 \text{ in}^3 \)

\[ L_c = 7.37 \text{ ft (Clause F1-2 page 5-45 of Manual)} \]

From observation load case 3 will govern, \( F_x = 24.06 \text{ kip (tension)}, M_z = 62.96 \text{ ft-kip} \)

From Clause F1-1, the allowable compressive stress is

\[ f_b = 0.66 F_y = 23.76 \text{ ksi} \]

Since section is in tension, per Clause F1-5 (page 5-45 of Manual)

\[ f_b = 0.60 \cdot 36 = 21.60 \text{ KSI} \]

Choosing the larger of above 2 values, \( f_b = 23.76 \text{ KSI} \)

\[ f_a = 24.06/10.6 = 2.2698 \]

\[ f_b = 62.96 \cdot 12/56.49 = 13.37 \]

Since combined tension and bending, use equation H 2-1, page 5-55 of the AISC ASD 9th ed. specs.

\[ 2.2698/(0.6 \cdot 36) + 13.37(23.76) = 0.105 + 0.5627 = 0.6677 \]

**Member 8**

Size L4x4x1/4, \( L = 7.071 \text{ ft}, a = 1.94 \text{ in}^2 \)

From observation load case 1 will govern, \( F_x = 23.04 \text{ kip (Comp.)} \)

\( F_a \) is computed as per page 5-310 of the AISC ASD 9th ed. specs.

\[ Q_a = 1.34 - 0.00447 \cdot (4/0.25) \cdot (36)^{1/2} = 0.9108 \]

\[ Q_a = 1.0 \]
\[ Q = Q_s \cdot Q_a = 0.9108 \]
\[ C_c = 92.0 \pi^2 \frac{E}{(Q \cdot F_y)^{1/2}} = [2.0 \pi^2 \cdot 29000/(0.9108 \cdot 36)]^{1/2} = 132.1241 \]
\[ KI/r = 7.071 \cdot 12/0.795 = 106.73 < C_c. \]

Hence, \( f_a = 11.6027 \text{ ksi} \) (computed per equation 4-1)

Actual compressive stress
\[ f_n = 23.04/1.94 = 11.876 \text{ ksi} \]

Therefore, Ratio = 
\[ f_n/f_a = 11.876/11.602 = 1.024 \]

**Member 9**

Size L5x5x3/8, \( L = 5.657 \text{ ft} \), \( a = 3.61 \text{ in}^2 \)

From observation, load case 1 governs, \( F_x = 48.44 \text{ kip (Comp.)} \)

\( Fa \) is computed as per page 5-310 of the AISC ASD 9th ed. specs.
\[ Q_s = 1.34 - 0.00447 \cdot (5/0.375) \cdot (36)^{1/2} = 0.9824 \]
\[ Q_a = 1.0 \]
\[ Q = Q_s \cdot Q_a = 0.9824 \]
\[ C_c = 92.0 \pi^2 \frac{E}{(Q \cdot F_y)^{1/2}} = [2.0 \pi^2 \cdot 29000/(0.9824 \cdot 36)]^{1/2} = 127.2238 \]
\( (KI/r)_{\text{min}} = 5.657 \cdot 12/0.99 = 68.57 < C_c. \)

Hence, \( f_a = 16.301 \text{ ksi} \) (computed per equation 4-1)

Actual compressive stress
\[ f_n = 48.44/3.61 = 13.418 \text{ ksi} \]

Therefore Ratio = 
\[ f_n/f_a = 13.418/16.301 = 0.823 \]
